INTRODUCTION*

TO THE ARTICLES ON INORGANIC CHEMISTRY.

IT has been thought advisable to include in an Addenda brief accounts of the chief work done in descriptive inorganic chemistry since the publication of Vols. I., II., and III., and the printing off the final proofs of Vol. IV.

Nothing bearing on organic chemistry has been included in the ADDENDA, as to give an account of what has been done in this department since the various volumes were published would occupy many hundred pages.

Dates are attached to the references made to original memoirs in the ADDENDA; and references are frequently made to abstracts of the memoirs in the Journal of the Chemical Society.

M. M. PATTISON MUIR.

INTRODUCTION

THE ARTICLES RELATING TO ORGANIC CHEMISTRY.

THE names used to denote ring formulæ are given below for convenience of

Since the publication of the last volume I have been assisted in the work of reading and making abstracts of original memoirs by Drs. T. Cooksey, T. A. Lawson, Samuel Rideal, Messrs. J. Wilkie, G. N. Huntly, and J. T. Norman. I have also been existed by Mr. Arthur G. Green and Mr. Cecil W. Cumhington in the work of revising the proof-sheets. I have great pleasure in thanking these gentlement for the energetic and Miscient manner in which they have carried out their share of the work.

H. FORSTER MORLEY.

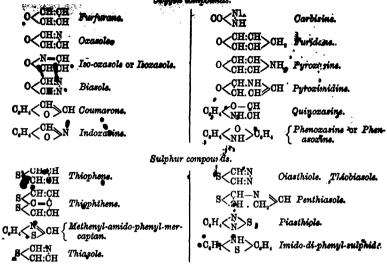

Nomenclature of Ring Formulæ.

Hydrocarbons.

OH, CH, Tri	imethylens.	•сн<сн Он Он	Tetramethenyl.
$CH_2 < CH_2 > CH_2$	Tetramethylene.	CH₂ <ch:ch< td=""><td>Pentamethenyl hydride.</td></ch:ch<>	Pentamethenyl hydride.
OH ₂ CH ₂ OH ₂ Pe	entamethylene.	с"н"<Сн >он	Indonaphthene.
	Nitrogen o	empounds.	
ин<сн:он	Pyrrole.		OH Pyridasine.
NH <n=ch< td=""><td>Pyrazole.</td><td>N≪CH:⊕H></td><td>N Pyrasins.</td></n=ch<>	Pyrazole.	N≪CH:⊕H>	N Pyrasins.
NH CH: N	Glyoxaline.	N≪CH:N CH.CH	CH Pyrimidine.
n≪ ^{oh.oh} ,	Metapyrasole.	n≪ch. n >	CH Triazoline.
$NH < \stackrel{OH:N}{\underset{CH:N}{\text{OH}}} \stackrel{\bullet}{\text{or}} N < \stackrel{OI}{\underset{CI}{\underset{CI}{\text{OH}}}}$	H.NH H:N <i>Triazole.</i>	$N \leqslant_{N:CH} N :_{CH}$	CH Osotetrasole.

                             " of a gas at constant volume.
 S.H. p. .
                Quantity of heat, in gram-units, produced during the complete com-
bustion of the mass of a solid or liquid body represented by its
                                                           pressure.
 H.C.
                      formula, taken in grams.
 H.C. v. .
                Heat of combustion in gram-units of a gram-molecule of an element or
                      compound, when gaseous, under constant volume.
H.C. p. .
                The same, under constant pressure.
                Quantity of heat, in gram-units, produced during the formation of the mass of a solid or liquid body represented by its formula, taken in
H.F.
                      grams, from the masses of its constituent elements expressed by
                    • their formulæ, taken in grams.
               Heat of formation of a gram-molecule of a gaseous compound from the gram-molecules of its elements under constant volume.
 ■.F. v. ..
H.F. p.
H.V.
                The same, under constant pressurce
               Heat of vaporisation of a liquid, i.e. gram-units of heat required to change
                     a gram-molecule of the liquid compound at B. P. into gas at same temperature and pressure.
T.C. .
                Thermal conductivity (unit to be stated).
8.V. .
                Specific volume; or the molecular weight of a gaseous compound divided
                      by the S.G. of the liquid compound at its boiling-point compared with
                      water at 4°.
               Specific volume of a solid; or the mass of the solid expressed by its formals, taken in grams, divided by its S.G.
S.V.S. .
E.C. .
               Electrical conductivity (the unit is stated in each case).
C.E. (10°
to 20°)
                Coefficient of expansion (between 10° and 20°).
                                           of a gas = volume dissolved by 1 volume of water.
of a liquid or solid = number of grms. dissolved by

    •
                 attached to nitrogen.
                 Employed to denote that the substituent is attached to a carbon atom
                        which is next, next but one, or next but two, respectively, to the terminal carbon atom. The end to be reckoned from is determined
        40
8
    .
                        by the nature of the compounds. Thus CH2.CHBr.CO2H is a-bromo-
                        propionic acid.
                  denotes that the element or radicle which follows it is attached to a ter-
                        minal carbon atom.
 α,β,γ,&ο.
                  indicate position in an open chain, only. .
 1,2,8, &c.
                  indicate position in a ring only.
                  Used when a, $, &c. are employed in a sense different from the above,
 (α), (β),
&c.
                  e.g. (a)-di-bromo-camphor.
Baeyer's Nomenclature:
 (B.) . . (Py.) . .
                        benzene ring.
                        pyridine ring
                        pyridine ring.

Thus (B. 1:8) dichloroquinoline, means a meta-dichloroquinoline in which the chlorine atoms are both in the benzene ring.

While (Py. 1:8) dichloroquinoline, means a similar body, only the chlorine atoms are in the pyridine ring. The numbers are counted from two carbon atoms which are in different rings; but both united
                         to the same carbon atom.
                  denotes the central ring in the molecule of afithracene, acridines, and
 (4.) . .
                         azines.
                  means that the element or radicle it procedes is in a closed ring.
 480-
                                                                                       not in a benzene ring.
                   denotes isomerism that is not indicated by ordinary formulæ; thus maleïe
 allo- .
                  acid may be called allo-fumaric acid.
denotes displacement of oxygen by sulphur.
 thio. .
                             the group 80.H, except in the word sulphocyanide.
 sulpho-
 sulphydro-
                             the group SH.
                  Tribromonitrobenzene sulphonic acid [2:2:3:4:5] means that the three bromines occupy positions 1, 2, and 8; the nitro-group the position 4,
```

and the sulpho- group the position 5. " Denotes that the formula to which it is affixed has not been determined by analysis. But it by no means follows that formulæ without this mark are those

analysed compounds.

All temperatures are given in degrees Centigrade unless when specially stated

Wavy-lengths are given in 10-' mm.
Formulas, when used instead of names of substances, have a qualitative meaning only.

Thomsen's potetion is used in thermochemical data.

DICTIONARY OF CHEMISTRY

PHENYL - AZOXAZOLE CH: NO. [30°]. (OPh: NO. [30°]. (OPh:

PHENYL - BENZAMIDINE C₁₈H₁₈N₁ i.e. C.H₁C(NH).NHPh or C₁H₁C(NPh).NH, [112°]. Formed from benzonitrile and aniline hydrochloride at 230° (Bernthsen, A. 184, 848; 192, 83). Formed also from benzimido ether and aniline, and from CPhCl:NPh and NH, (Kobbert,

**Manufacture of the state of t 8. CS, at 100° forms thio-benzanilide and phenylbenzamidine sulphocyanide.-4. Reduced by sodium-amalgam to C.H., CH(NH₂). MHPh. — 5. Nitrous acid forms benzanilide (Mieran,

4. 265, 141). The derivatives The derivatives C.H.C(N.SO.Ph).NHPh [189°] and C.H.(SO.N.C(NHPh).C.H.), [196°] have been prepared (Wallach, A. 214, 214;

Jackson, Am. 9, 846).

s - Di - henyl - bensamidine • C₁₁H₁₄N₂ i.s.

C.H. C(NPh) NHPh. [144°].

Formation.—1. From benzamilide by treat-

Formation.—1. From benzanilide by treatment with PCl, and aniline (Gerhardt, A. 108, 219; Hofmann, 5-1866, 161; Wallach, A. 184, 88).—2. From Ph.CCl, and aniline with or without ZnCl, (Limpricht, A. 135, 82; Döbner, B. 15, 283).—3. A produce of the action of aniline hydrochloride at 250° on benzonitrile, thiobenzamide, or phenyl-benzamidine (Bernthsen, A. 184, 352).-4. By heating benzanilide with phenyl cyanate at 190° (Kühn, B. 18, 1476)...5. By heating the hydrochloride of benzimido-ether in alcohol with aniline for a long time (Kobbert, A. 265, 155).

Properties.—Needles (from alcohol), m. sol.

beasene. Its alcoholic solution is neutral to litmus. Not affected by nitrous acid. Split up into aniline and benzanilide when boiled for a

leng time with alcohol.

Rections.—1. Dry H.S at 160° forms thic-Realtions.—1. Dry H.S at 160° forms thickness and the second of the seco

Its alcoholic solution turns litmus blue. Conc. H₂SO₄ gives a violet blue colour on warming.

Reactions.—1. Dilute HClAq as 180 forms.

NPh.Bs.—2. The free base and its hydrochloride yield benzonitrile and diphenylamine on heating—3. Nitrons soid forms Ph_Bs (Klobbert, A. 265, 157).—4. H₂S at 130° forms Ph.CS.NH₂, dippenylamine, Ph.CS.NPh₃ and NH₄₅—5. CS, at 140° forms Ph.CS.NPh₃ and HNOS.—Salts.—B'HCl. [c. 228°]. Moncolinia

Saits.—B'HCl. [c. 225°]. Moncelinie crystals, a:b:c=529:1: 507; \$=85°52'. V. sol. water, sol. alcohol, insol. ether.—B-H-2PtCl.—B'HNOS. [208°]. Yellow prisms.
PHENYL-BENZAMIDOXIM

PHENYL-BENZABIDULIE

C.H.,C(NOH).NHPh. [188°]. Formed by boi
ing C.H.,CS.NHPh with an alcoholic solution a
hydroxylamine (Müller, B. 19, 1669). Needles
(from water). Yields BERGI. CICO.Et forms

CI.H.,N.O. [187°].

DI.PHENYL-BENZAZIDINE C.H.,N. d.c.

H. C. MEDEL NH NHPH. [170°]. Farmed by

C.H.C(N.MHPh).NH.NHPh. [179°]. Termed by the action of phenyl-hydrasine on PhCQl, or on the hydrochloride of benz-imide-ether dissolved in absolute alcohol-(Pinner, B. 17, 182; Marckwald, C. C. 1888, 1410). Dark-red needles. PHENYL-BENZENE v. DIPHENYL.

p.Di-phenyl-bensene C.H. i.e. C.H.Ph. Mol. w. 290. [207°]. (c. 405°). Formation.—1. A product of the action of sodium on an ethereal solution of p-di-bromobenzene, or, better, of a mixture of p-di-bromo-benzene with bromine (Riese, Z. [2] 6, 192, 785; A. 164, 168).—2. Tegether with its isomeride, and other products, by passing the vapour of benzene, or of a mixture of benzene. and toluene, through a red-hot tube (G. Schultz, B. 6, 415; A. 174, 280; 208, 118; Carnelley, C. J. 37, 712).—8. Together with the isomerida and other products, by the action of AlCl, on a mixture of MeCl and diphenyl (Adam, Bl. [2] 49, 97; A. Ch. [6] 15, 241).
Properties.—Needles (from bensene), or iri-

descent laminæ (by sublimation); insol. alcohol, v. al. sol. HOAc. Its solution in benzene shows blue fluorescence. Conc. H,SO; gives a dirty The fluorescence. Conc. H₂SU₂ gives a dirty green solution changing to purple. GrO, in HOAc oxidises it to diphenyl p-earboxylic [3167] and terephthalic scids. Does not form a compound with piorie acid. Not volatile with stearity lields C₁₆Cl₁₆ on exhaustive chilerination with SbCl₁ (Mern a. Weith, B. 16, 2884).

References. — Brown and Tax-critical. Dt.

PRENTL-BUNKENS Iso-di-phenyl-benzene C, H,, [85°]. (c. 870°). Formed as above. Slander prigns, v. sol. al. Rormed from benzamidine hydrochloride, phenyl cyanate, and NaOHAc (Dispute of the control of the Nacias, and NaOHAq (Pinner, B. 22, 1607).
Nacias, inc.). water, v. sl. sol. hot alcohol.
PHENYL-BENZIMIDO-ETHEE C, H, NO i.e. OPh(NPh).OEt. A product of the action of aniline on bensimido-ether (Lossen, A. 265, 138). Oil. Decomposed by conc. HClAq into EtCl and benzanilide. PHENTL BENZOATE v. Benzoul derivative of PHENOL PHENYL. RENZOIC ACID of DIPHENYL-CARR-OXYLIC ACID. ONTLICATION.

PHENYL-BERZOPHENOME C₁₂H₁₁O.i.e. [1:4]

C.H., C.H., C.H., ClO4*]. V.D. 9*0. Formed by oxidation of p-benzyl-diphenyl with chromic acid (Goldschmiedt, M. 2, 487; Köller, M. 12, 10).

ENTLY Parad also from diphenyl Bell, and 501). Formed also from diphenyl, BzCl, and AlCl. (Wolf, B. 14, 2032). Scales, sol. alcohol. Yields benzophenone-p-carboxylic scid on further oxidation by CrO.

Oxim. [1946]. Needles. When HCl is passed into its solution in HOAc containing and the mixture heated in sealed tubes Ad 0 and the mixture nearest in scales successions. 100°, it is converted into the isomeric O.H., C.H., CO.N.H.C.H., 1224°]. The oxim is reduced by sodium-amalgam to the corresponding amine C.H., C.H., C.H.(N.H.), C.H., [77°]. Bensoyl derivative of the Oxim [198°]. Needles (from alcohol). Phenyl-hydraside. [144°]. medies (from dilute alcohol).

10 - phanyl. benzophenone (C,H,C,H,),CO.

120 - Rormed by the action of COCl. on
diphenyl in presence of AlCl. (Adam, Bl. [2] 47,
638]; A. Gh. [6] 15, 259). Got also by oxidising
CH-(C,H,Ph), (Weiler, B. 7, 1188). White needles,
sol. acctone, v. sl. sol. alcohol. Not attacked by
toming HNO, or by H,SO, and HNO, at 100°.
By adding Na to its solution in alcohol-benzene
life reduced to (C,H,C,H,),CH,OH, [151°], S.
(chert) 5; S. (Scohol) 1:25 at 15°. Potash-fusion
mile, diphenyl.-p-carbof-pile acid [218°].

de blos allowed about the

Arti-phenyl-beasene C.H., i.e. C.H.M., Mol. v. 866. [13°]. (shows 860°). Formed from actiophanone by treatment with F.O., with alcoholie NH., or with dry HCl (Engley, B. 6, 688; 7, 1128). Formed also by heating O.H.(O.H., CO.H.), tith KOH (Gabriel a. Michael, B. 11, 1007). It is also a by-product in the action of actiophenone on dimethylaniline in presence of 2nCl? (Dopper a. Petachoff, A. 242, 389). Trimetricerystals; a: to = 566:1: 766, affsol. alcohol. Yields benzole acid on oxidation by Cro. in HOAc (Mellin, B. 28, 2583). By exhaustive chlorination with SbCl, it yields penchloro-triphenyl-benzene (Merz a. Waith, B. 18, 2883). On heating with I and red R at 27%; it yields the crystalline dodeca-hydride C.H., and finally oily C.H., (Mellin, B. 28, 2584). Fuming H.SO, at 100° forms a disulphonic acid, which yields the Bastl C.H.S.O.Ba crystallising immedles.

Ba salt C.H.S.O.Ba crystallising inmeedles. •.
PHENYL BENZENE SULPHAZIDE Phonyl-hydraside of Benzene aulphonic acid. DE-PHENYL-BENZENYL-DI-URBA

PHENYL-BERZOYL IS HERSOFFERD
PHENYL-BERZOYL AGENTO AGEN
CHBerh.CO.H. Wethyl sther MeA'. Form
from de-oxybensoin, McOEt, and CIOO,
(Rattner, B. 21, 1816). Oil, decamposed by d
tillation into C.H.Ph., CO., and HOBs.
PHENYL-BERZOYL-BUTYRIC ACID CHBzPh.OH., CH., CO.H. (B) Beyl-propion acide [186°]. Formed from deoxybenzoi NaOEt, and \$\text{Biodo-propionic ether (Knoevenag B. 21, 1344). Needles. Bields MeA' [64 and EtA' [84°].

PRENTL BENZOYL is BENZOPHENOMA.

The isomeric acid CHBzPh.CHMe.CO, [215°], formed from \$\theta\$-bromo-propionic acid, less sol, alcohol and ether.

PHENYS-BENZOYL-CARBINGL v. BENZOÏ

PHENYL-BENZOYL-PROPIONIC ACID CHBzPh.CH. CO.H. [186°]. Formed from d oxyberzoin, NaOEt, and chloro-acetic eth (Meyer a. Oelkers, B. 21, 1295; Knoevenage 21, 1344). Small tables (from alcohol). Di-phenyl-benzoyl-propionic acid CH,Bz.CPh,CO,H. [183°]. Got by the action (

alcoholic potash on the lactone of oxy-tri-pheay crotonic acid (Japp a. Klingemann, B. 22, 2882 Yields a phenyl-hydrazide C₂₂H₂₁N₂O [185° and an oxim C₂H₂₁N₂O, [152°].

**PHENYL-EENZYL ALCOHOL C₁₂H₁₂O i.

C₄H₂Ph.CH-OH. Got from C₄H₂Ph.CH, by trea

ment with Br and alcoholic potash; the resultin syrupy C.H.Ph.CH.OEt being treated with H (Adam, Bl. [2] 49, 97). Syrup. PHENYL-BENZYL-AMIDO-DI-PHENYI

METHANE C. H., N. i.e. CH., Ph.C., H., NPh.C., H. Formed by heating NPh,H (1 mol.) with bens; chloride (2 mols.) and ZnCl, at 210° (Meldols C. J. 41, 200). Solid; s. sol. ether, insol. alcoho and HOAc. PHENYL-BENZYL-AMINE v. BENZYL-ANIL

Nitrosamine C.H.NPh.NO. [58°]. Needle (Antrick, A. 227, 8860). Yields benzyl-anilinand benzyliden-aniline on treatment with alcoholic HCl (O. Fischer, A. 241, 378). Phenyl-di-bensyl-amine v. DI-BENZYL-ANL

Di-phenyl-benzyl-amine NPh, CH,Ph. [87°] Ot from C.H., CSNPh., zinc-dust, and HCla'd (Bernthsen a. Trompeter, B. 11, 1761; cf. Wilm a. Girard, B. 8, 1196). Needles, al. sol. cold alcohol. Yields a green dye on heating with HClAq and arsenic acid (Meldola, B. 14, 1885). DI-PHENYL-DI-BENZYL-TETRAZONE

NPh(CHPh).N:N.NPh(CH.Ph). [109]. Formed from (a)-phenyl-benzyl-hydrazine. CHCl., and HgO (Michaelis a. Philips, A. 252, 290). Needles. PHENYL-BENZYL-CABBINOL C. H.O. i.e. CH.Ph.(H(OH).C.H., Toluylene hydrate. [62°]. Formed by reducing deoxybenzoln, and by the action of alcoholic potath on the same body action of alcoholic potash on the same-body (Limpricht a. Schwanert, A. 185, 62; Golden-berg, A. 174, 882; Zagoumenny, A. 184, 185; Anschütz, A. 261, 298). Formed the (827) by the action of nitrous acid on CH.Ph.CHP.R.H., (Leuckart, B. 32, 1410). Long similar modelles (from alcohol), inkol. water. Reduced by Hida to dibensyl. Yields a liquid accept derivative. PHERYL RESINIL EXPER a Plengle of the of Bennyl. Access. of Brauer, Appelion. C. J. 1919. Formed from ethyl-thio-cartonide and bensyl-atiline in alcohol (Dixon, O. J. 50, 568). Rectangular frams, insol. cold vater, v. e. sol. boiling alcohol.

An isomeride [91] uncor.] formed from bensyl-thiocartonide and ethyl-aniline crystallises in oblique frisms grouped in rosettes.

PHENYL-MENYL-HYDRAZINE C.H.H.N. CH.Ph.NPh.NH. [269]. Formed from

i.s. CH_Ph.NPh.NH. [26°]. Formed sodium phenyl-hydrazine and benzyl chloride, and got also by reduction of phenyl-benzyl mitrosamine (Antrick, A. 227, 661; Michaelis a. mitrosamine (Antrick, A. 227, 501; Michaells a. Philips, A. 252, 286). Needles (containing aq), decomposed by heat. Benzoic aldehyde forms CH,Ph.NPh.N:CHPh. [111°]. In benzene solution it gives with SOCl, the thiony compound C,H,NPh.N:50Z[65°] (Michaelis a. Ruhl, A. 270, 122). C,HPCl, forms C,H,NPh.N:PC,H, [147], crystallising from ether in needles.—EHCl. [167]: colourless needles. Benzene phosphinate B'O.H.,PH₂O₂ [108°] (Michaelis, A. 270, 185).

Acetyl derivative. [121°]. Scales. Bensylo-chloride (C,H,),NPhClNH,

PHENYL-BENZYLIDENE-ALLYL-HYDRA-ZINE NPh(C,H₄).N:CHPh. [52°]. Formed from phenyl-allyl-hydrazine and benzoic ablehyde (Michaelis a. Claesson, B. 22, 2237). s, v. sol. ether and hot alcohol

PHENYL-BENZYLIDENE-AMINE v. BENZ-YLIDENE-ANILINE.

Phenyl-benzylidene-diamine C.H. CH(NH.)(NHPh). [115°]. Formed by reduction of phenyl-benzamidine with zinc and Hol (Bernthsen a. Szymanski, B. 13, 917).

Small crystals.—B'HCl. (224°). Thick prisms.

—B',H,PtG; : spikes or plates.

DI-PHENYL-BENEYLIDENE. ETHYLENE.

DIAMINE CHPh NPh C.H. [187°]. Formed from benzoid aldehyde and di-phenyl-ethylene-

from cenzous agenyae and up-puenya convented diamine (Moos, B. 20, 432). Needles, split up by the convented from the parent bodies.

PHENYL - BERZYLIDENE - ETHYL
RYDRAZINE PHNELN:CHPh [59°]. Formed the convented for the conven

from benzoio aldehyde and phenyl-shyl-hydrazine (Michaelis a. Philips, A. 252, 272). PHENYL-BENZYLIDENE-HYDRAZINE v.

Phenyl-hydraside of Benzhio Aldehyde.
DI-PHENYL-BENZYLIDENE-DI-INDOLE CHPh(C14H16N)2. [268° uncor.]. Formed from CHPh(C₁,H₁,N)₂. [200 uncor.]. Formed to bensoic aldehyde and C₂H, CH CPh (E.

Fischer a. Schmidt, B. 21, 1074). Slender leaflets, v. sl. sol. hot alcohol. PHENYL-BENZYL-INDOLE

AlCl, on a mixture of phenyl-acetyl chloride and benzepe (Graebe a. Bungener, B. 12, 1879). 6. From phenyl-acetic acid, benzene, and P.O. (Zincke, B. 0, 1771).—7. By the action of alcoholic ammonium sulphide (or KHS) on bensil (Zinin, J. pr. 38, 35; Jena, A. 155, 87).—8, By dissolving s-di-phenyl-acetylene in H. SO, and adding water (Béhal, Bl. [3] 49, 387).

Properties—White plates (from alcohol); al. sol. hot water, volatile with steam.

Reactions.—1. On heating with alcoholic potagh it yields phenyl-benzyl-carbinol and diethyl carbobenzonic acid C₁₈H₁₀(100°), which gives Eth' (309° at 11 mm). (Zagoumenny, A. 184, 163; Anschütz, A. 261, 298). The acid C₁₈H₁₀O₁ is converted by P and HI into an isomeric acid (184°), by HNO, (S.G. 1.18) into C₁₈H₁₀O₂ (196°), by conc. HNO, into C₁₈H₁₆(NO₂O₂ (156°), and by potashrusion into β-benzyl-isobutyric acid.—2. KOH in propyl. alcohol at 150° forms C₂₈H₂₆O₂ (90°) and also an isomeride (139°) which yields C₂₈H₂₆(NO₂)O₂ (176°).—3. KOH in isobutyl alcohol at 140° forms dissobutyl-carbobenzonic acid C₂₈H₂₆O₂ (148°), S. Reactions .- 1. On heating with alcoholic isobutyl-carbobenzonic 'acid C,H,O, [148°], S. (alcohol) 5. The homologous isoamyl compound S₂H₂O₂ [160] may be got in like manner.—4. Reduced by HI to di-phenyl-sthylene and di-phenyl-ethane.—5. Sodium-amalgam reduces it to O₂H₂O₂ and finally to phenyl-benzyl-agrinol.— On Ing. Og and many to pneny - pensy compounds yield oxims melting at 107° and 141° respectively. Fuming HNO₂ (S.G. 1-51) at 0° forms three isomeric di-nitro derivatives at 0° forms three isomeric ol-niero- univasaves [116°], [126°] and [155°] (Golubeff, B. 18, 2408; J. R. 18, 23).—7. Bromine forms C_{1,}H₁,BrO [55°] (Knoevenagel, B. 21, 1355) and C₁H₂,Co.OBr.C.H₁ [112°].—8. PCl. yields CHPh:CClPh.—9. Alcoholic potesh and bensoic aldehyde form benzamarone C, H, O, (215°] (Japp a. Klingemann, B. 21, 2984; cf. Zinin, Z. 1871, 127).-10. NaOEt and nitrous said yield the mono- oxim of benzil.—11. NaOEt and CSCl. yield golden (C.H.C(CS).CO.O.H.).
[2869] (Bergreen, B. 21, 850).—12. NaOEt and MeI yield phenyl phenyl ethyl ketone C.H. CO.OHMePh. Other alkyl fodides act in like manner (V. Meyer, B. 21, 1295).— PHENYL BENZYL INDOLE Unit of discounting the phenyl-hydraxide of d 13. Sodium acting on a bensens solution in absence of air forms C.H., CO.CHRa.C.H., a very hygroscopic yellow substance converted by CO.

anilha yisis ibanyi baniyi ketone, tri-phanyi-ganidine, and H.S.
Osim C.H.CR. C(NOH.C.H., [98°].

Phanyi-Nydraside
CH.Ph.C(N.HPh.Ph. * [108°]. Needles (from sleadhol) (May B. 21° 2447).

PHENYI BENZYI INTONE-c-CARBOXYLIC ACID C_{1.H.1}Co : s. C.H., CO.C.H., C.H., CO.H.
Decrybersolm-carboxpilic acid. [168]. Formed by heating isobenzylidene-phthalide with NaOH (Gabriel, B. 18, 2448). Needles, sol.
dlacohol. Reduced by sodium-amalgam to C.H., CH.(OH). CH., C.H. Ammonia forms isobenzylidene-phthalimidine. Hydroxylenine hydrochloride in Stocholic solution at 100°

ALTO OFFICE OFFICE AND A STATE OF Anhydride v. Isobenzylidene-phthalide.

Methylamide CH,Bz.C,H,CO.NHMe. od methylamine in alcohol at 100° (Gabriel, . 20, 2866). White needles.

Phenyl benzyl ketone o-carboxylic acid

Phenyl bensyl ketone o-componytic acia H. CH. CO.C. H. CO.H. Decaybenzoin-ecarb-iglio acid. [75]. Formed by boiling benz-idene-phthalide with KOHAq (Gabriel a. ichael, B. 11, 1018). Prisms (containing aq). AgA': Crystalline pp. Anhydride v. BENZYLIDENE-PHTHALDE.

Amide CH,Ph.CO.C,H,.CO.NH, [166°]. ormed from benzylidene-phthalide and alcoilio NH, at 100° (Gabriel, B. 18, 2434).

iedles, sol. hot water, converted into henzyl-iedles, sol. hot water, converted into henzyl-idene-phthalimidine by boiling with HOAc. Ethylamids OH_Ph.CO.C.H.,CO.NHEt. [140°]. Formed from benzylidene-phthalide and alcoholic NEtH, at 100° (Gabriel, B. 18, 1258, 2484). Converted by boiling HOAc into C.H. CO(CHPh) NEt. [77°]. Hydroxylamine

forms C,H, C(CH,Ph) N [177°], which is also formed by the action of hydroxylamine on

phenyl benzyl ketone carboxylic acid.

Phenyl benzyl ketone dicarboxylic acid.

C_tH₁(CO_tH).CO.CH₁.CJ.H..CO_tH. [239°]. Formed together with an isomeride [250°] by heating phenyl-acetic-o-carboxylic acid with phthalic anhydride and NaOAc at 190° (Ephraim, B. 24, 2621). Needles. Gaseous HCl acting on its alcoholic solution forms the anhydride O_*H_* COH, COO, $O_*O_*H_*$. [260°]. Hydroxyl-

C,H,<CO,H,.CO,H yields [280°] crystallising in needles. Alcoholic NH, forms crystalline C, H, NO. PHENYL-BENZYL-METHYL-AMINE

FHENYL-BENZIL-MEINIL-AMANA G.H.N i.e. NMePh.CH.Ph. [306°] (Nölting, M. S. [8] 18,88). Methylo-chloride B'MeClaq. [110°]. Formed from di-methyl-aniline and benzyl wormed from di-metayl-aniline and beinsyl abloride (Michler, B. 10, 2079). Tables, v. sol.
water and alcohol. Converted by successive freatment with Ag,80, and baryta into a syrupy bydroxide, which is split up on distillation into Sensyl alcohol and dismethyl-aniline.

FRENTL BENZYL-BENZYL-BENZYL-WETHYL-TRIO-URBA

O.H. N.S. i.a. NPhMc.CS.NHC.H.. [85] Formed from bensyl-thiocarbimide and methyl-sniline (Dizon, C. J. 59, 568). Prisms.

Inqueries NEME CENTRO H. (MI) Formed by boiling methyl-thiocarbimide with bensyl-aniline in alcoholic solution (D.). Talks of white prisms, L. sl. sol. hot water. PHENYL-BENEZYL-METHYL-UREA

CH.Ph.NH.CO.NPhMe. 847. Formed from CH.Ph.NH.COCI and methyl-miline (Kühn a. Riesenfeld, B. 24, 8817). V. sel. alcohol.

EENZYL-PHENYL-NITEOSAMINE
C.H.NPh(NO). Nitrosamine of bensyl-amiline. (10 g.).

[589]. Formed from bensyl-amiline (10 g.).

salobio (126 c.o.), H.SO. (6 c.o.), and NaNO, in the cold, the product being poured into water (500 c.o.) (Antrick, A. 227, 860). Pale-yellowish needles, v. sol. alcohol and ether.

PHENYL-BENZYL-OXIDE v. Phenul ether

of BENZYL LOCHOL.

PHENYL BENZYL-PHOSPHLER?

CH-Ph.PHPh or C. H., P. [171°]. Formed by heating C.H., PCl., with benzyl chloride and zinc (Michaelis a. Gleichmann, B. 15, 1961). Needles, believe the state of the shoring of the state of

converted by successive treatment with chlorine

conversed by successive treatment with chlorine and slikelis into C,H,PO or C,H,P,O, [156].

Di-phenyl-bensyl-phosphine dichloride C,H,PCL,(C,H,), [187°]. Formed from (C,H,PCl and benzyl chloride at 180° (Dörken, B 21, 1506; cf. Michaelis, B, 18, 2117). Priams.

Di-phenyl-bensyl-phosphine oxide
C.H.PO(C.H.). [198°]. Formed by decomposing the preceding body with water. Yields a

tri nitro- derivative [206°].
DI-PHENYL DI-BENZYL-SUCCINIC ACID. Nitrile. CN.CPh(CH,Ph).CPh(CH,Ph).CN. [235°]. Formed from CN.CNaPh(CH,Ph) and I

(235). Formed from UN.UNAFII(CH₂FI) and I (Chalanay a. Knoevenagel, B. 25, 290). White crystalline powder, sl. sol. alcohol.

PHENYL BENZYL SULPHONE C₁₂H₁₂SO₂₆

£. C₂H₂SO₂CH₂Ph. [148°]. Formed from C₂H₃SO₂O₃Na and benzyl chloride (Knoevenagel, B. 21, 1344). Sl. sol. ether₂m.*sol. alcohol.

DI.PHENYL-BENZYL-THIOSENIGAEBAZ-TENDEL (H. N.N. C. N. DE).

DI-PHENNI-BENZYI.-THIOSEMICARBAZ-IDE NPh(C,H.),NH.CS.NHPh. [1509]. Formed from phenyl-benzyl-hydrazine in alcohol and phenyl-liflocarbinide [Michaelis a. Philips, A. 252, 289). Crystals, v. sol. test alcohol. PHENYI.-BENZYI.-THIO-UREA C_{1.}H.,N.S. i.e. NHPh.CS.NHCH.Ph. [154°]. Formed by mixing alcoholic-solutions of benzylamine and phenyl-thiocarbimide (Dixon, C. J. 55, 300). Prisms (from alcohol), sl. sol. Cs. Phenyl-di-benzyl-thio-urea C_{1.}H.,N.S. i.e. NPh(C,H.),CS.NH.C,H., [103°]. Formed from phenyl-thiocarbimide and benzyl-aniline (D.). White prisms, v. sl. sol. hot water.

pnenyi-mocarounde and benzyi-aniline (D.). White prisms, v. sl. sol. hot water.

PHENYL-BENZYL-p-TOLYL-BIURET

C₃H₁₁N₄O₂. [95°-104°]. Needles (from dilute alcohol) (Kühn a. Henschel, B. 21, 504).

PHENYL-BENZYL-UREA C₁H₁N₄O i.e.
NHPh.CO.NHOH.Ph. [168°]. Formed by mixing benzyl cyanate with aniline (Letts, C. J. 25, 448). Needles, v. sol. alcohol.

Phanyl-di-henzyl-urea C. H. N.O. [1980]

A48). Needles, v. sol. alcohol.

Phenyl-di-bensyl-ures C₂₁H₂N₁O. [128°].

Got from (O,H₂), N.COCI and spiline (Hammerich, B. 25, 1819). Silky medies (from

alcohol).

PHENYL-BISMUTHINE v. vol. i. p. 517.

PHENYL-BIURET C.H.N.O. t.a. 2.

NHPh.CO.NH.CO.NH... Formed from phenylures and POL. (Weith, B. 10, 1744). Crystals.

s.Diplenyl-biuret NH(CO.NHPh). [310].

Formed by boiling alloghants asher, biums, or

Sales other, with aufline (Hofmann

And Scher, 188 aniline (Hofmann, R.S. 250; Lauchart, J. pr. [2] 21; 27). Formed also by the action of phenyl syanate on phenyl-ures (Rühn a. Henschei, B. 21, 504). Needles. 4-Di-phenyl-biaret NH, CO.NPh.CO.NHPh. [165°]. Got from di-phenyl disyanate and alcoholic NH, (Hotmann). Prisms, sol. alcohol. a-Tri-phenyl-biaret NPh(CO.NHPh), [148°]. Formed from di-phenyl disyanate and aniline (H.) and by heating phenyl syanate with di-phenyl-ures at 150°. Prisms (from alcehol). An isomeride [165°] was gog by Schiff (B. 3, 651) by distilling phenyl-carbamb ether. References.—Di-Bromo-Dr. and Oxy- PHENYL-

References .- DI-BROMO-DI- and OXY- PHENYL-

BIURET.

PHENTI-BORATE C.H.BO. Formed by heating phenol (3 pts.) with B.O. (2 pts.), or, better, by heating tri-phenyl borate with alcohol at 150° (Sahiff, A. Suppl. 5, 202). Sticky mass. Tri-phenyl borate (C.H.), B.O. Formed by boiling phenol with B.O. Glassy mass, decomposed by hot water.

posed by hot water.

Tetra-phenyl diborate (C.H.), B.O. S.G. 1124. Formed, with the preceding body, by heating C.H.BO, at 350°. Thick oil, quickly de-

composed by water.

Phanyl-boric acid C.H.,B(OH), [204°].

Formed from C.H.BCl, and water (Michaelis a. Becker, B. 15, 181). Needles, sol. alcohol, ether, and hot water. Powerful antiseptic, with ether, and hot water. Powerful antiseptic, with but slight physiological action. With HgCl, it gives a pp. of PhHgCl. Reduces ammoniacal AgNO₃, forming a mirror. On heating, it yields the oxide C₄,BO [190°] (above 860°), which forms crystals, sol. alcohol.

Salts.—NaA": dimetric tables.—CaH₂A"₃: crystals.—AgHA": yellow pp.

Ethyl ether Et,A". (176°). Oil.

Chlorida v. volai. p. 581.

Chloride v. vol. i. p. 531. PMENYL BROMIDE v. BROMO-BENZENE. PHENYL BROMO-ALLYL OKIDE v. Bromoallyl derivative of Phenol.
PHENYL BROMO-BENZYL KETONE

C.H., CO.CHBrPh. [55°]. Set by brominating phenyl benyl lessone (Knoevenagel, B. 21, 1856).

PHENYL BROWO BUTYL KETONE
C.H., CO.CH., CH., CH., CH., E. [61°]. Formed

from phenyl oxy-butyl ketone anhydride or its carboxylic acid and cone. HBrAq (W. H. Perkin, jun., C. J. 51, 732; B. 19, 2559). Six-sided plates, v. sol. alcohol. Converted by warm alcoholic potash into the parent

CH, CH, CH, O.

Phonyl di-bromo-butyl ketone C.H. CO.CH. CH. CHBr. CH.Br. Formed from

allyl-acetophenone and Br (Perkin, C. J. 45, 188). Oil. Bromine yields C, H, Br. 0 [122°] esystallising from dilute alcohol in prisms.

PHENYL BROMO-ETHYL KETONE C.H., CO.C.H.Br. Formed from phenyl ethyl strone and Br in CS, (Pampel a. Schmidt, B. 19, 2897). Oil with pungent odour.

PHENEL ROBO-ETHYL OXIDE v. Bromo-

ethyl derivative of PHENOL.
PHENYL BROMG-ETHYL SULPHONE C.H.SO.CHMEBr. [50°]. Formed by boiling an aqueous solution of the Na salt of the acid C.H.SO.CMEBr.CO.H [184°], which is got by bromination of C.H.SO.CMEH.CO.H (Otto, 27 [2] 49, 550). Rectangular takes. PHENYL BROMO-IMESATIN O. ISATIN.

PHENYL - BROMO-MATHEMYL-DI-ETHYL. FHENTL-SEWEU-BERTHEN IN-DI-BUNG.
TRI-SULPHONE C.H. SO. CORTSO, CARL.
[1357]. Formed by bromination of the sulphone
CH(SO,Ph)(SO,Et), (Leves, B. 25, 884). Plates
(from alcohol) or needles (from Aq).
TRI-PHENTL-BROWG METHERYL

SULPHONE OBr(SO,Ph), (255°). Got by brominating CH(SO,Ph), (Laves, B. 25, 851). Amorphous insoluble pp.

PHENYL BROMO-METRYL KETONE v. w-Bromo-acetorhienone.

PHENYL BROMO-METHYL SULPHONE

PHENYL BROMO-METHYL SULPHONE
C.H., SO., CH.Br. [48°]. Formed, together with
C.H., SO., CH.Br. [78°]. From C.H., SO., CH.C.O.H
and Br (Otto. J. pr. [2] 40, 542). Both compounds
form monoclinic tables, v. sol. hot alcohol.

PHENYL BROMO-(a)-NAPHTHYL RETONE
C.B., CO.C., C.H.Br. [98°]. Formed by brominatien of paenyl (a)-naphthyl ketone (Eibs a.
Steinike, B. 19, 1966). Yields a crystalline dinitro. derivativa decomposing at about 90°. nitro derivative decomposing at about 90°.
Yields C, H, Br(SO, H) [116°] on sulphonation.
PHENYL - BROMO - NITRO - METHANE v.

BROMO-NITRO-TOLUENE

PHENYL-BROMO - DI - NITRO - PHENYL -AMINE v. Bromo-di-nitro-di-phenya-amine.

AMINE v. BROMO-DI-NITRO-DI-PHENWI-AMINE.
PHENYL - BROMO - NITRO - PHENYLHYDRAZINE C₄H₂, N₂H₂C₄H₂Br(NO₂), [3:14],
[165°]. Formed from phenyl-hydrazine and
C₄H₂Br(NO₂), (Willgerodt, J. pr. [2] 87, 458).
PHENYL-p-BROMO-PHENYL-HYDRAZINE
C₄H₂N,H₂C₄H₂Br. [115°]. Formed by reduction of C₄H₂N,C₄H₃Br. [115°]. Formed by reduction of C₄H₂N,C₄H₃Br. [115°]. Tables.
PHENYL BROMO-PHENYL FETONE **

PHENYL BROMO-PHENYL KETONE .

Bromo-benzophenone.

DI-PHENYL BROMO-PROPYLENE DISUL. PHONE C.H.Br(SO.Ph). [160°]. Got from CH.Br.CH.Br and NaSPh in alcohol (Stuffer, B. 28, 1411). Needles.

PHENYL BROMO-PROPYL KETONE

C.H. CO.CH. OH. CH.Br. [89°]. Formed from benzoyl-trimethylene carboxylic acid and fuming HBr (W. H. Perkin, jun., C. J. 47, 844). Crystalline mass, v. sol. alcohol.

PHENYL-BUTANE v. But A. Benzene Di-phenyl-butane CH,Ph.CH,.CH,Ph. [52°]. Formed by heating di-phenyl-butylene with HI and P at 250° (Freund a. Immerwahr, B. 25, 2858). Crystals, v. sol. alcohol. Di-phenyl-butane CHMePh.CHMePh.

[128.5°]. Formed by the action of sinc-dust or [123°5]. Formed by the action to annual state of the American Ma on CHMePhBr (Radziszewski, B. 7, 142; Engler, B. 7, 1127). Needles (from ether). Di-phenyl-butane CPh.MeEt. [128°].

Formed from CPh, Me.CO.OH., phosphorus, and HI (Zincke a. Thorner, B. 11, 1990). Tables or prisms, m. sol. alcohol.

prisms, m. sol. alcohol.

De pheryl-butane CH, CH(CH,Ph), (800°).

Formed by heating acetophenone with HIAq and P at 180° (Graebe, B. 7, 1037). Oil.

References.—Amido-, Tel-chilono-, and The CHLORO-DI-MITRO- and OIL-PREMIS-BUTAMES.

PHENYL-BUTAME FRICAR BOXYLIG ACTD.

Ethyl sther C.H.,CH.,C(CO,Rt), CHMs.CO,Rt. (388° cor.). S.G. \$9 1.1008. \(\mu_2\) 1.4850 at 20°.

Four 2 from sodium-propens tri-carboxylie ether and benzyl chloride (Bischoff a. Minty.)

Insol. water. Combines with Br. Excess of Br added to a glacial acetic acid solution forms

promo-phenyl-butenyl ketone dibromide, [120°].
PHENYL-BUTINENE C, L., i.e. OPh:CRt.
Phenyl-sthyl-acetylene. (202°). S.G. 21 923. Premyl-stray-acetylene. (202"). 5.9. 2020. Formed from sodium phenyl-acetylene and EtI (Morgan, O. 7. 29, 162). Liquid. Phenyl-butinene CieHip. (185°—190°). Got from CH.Ph.CH.CH.Br.CH.Br and alcoholic potash at 180° (Aronheim, A. 171, 231). Liquid.

Di-phengl-butines CHPh:CH.CH:CHPh. [148°]. (820°-840°). Obtained by heating CHPh:CH.CH:CPh.CO.H (Rebuffat, G. 15, 107; 20, 154). Micaceous plates.

References .- AMIDO - and OXY - PHENYL -

PHENYL - BUTINENE DICARBOXYLIC ACID CHPh:CH.CH:C(CO.H), [208°]. Formed by heating cinnamic aldehyde with malonic acid and HOAc at 100° (Stuart, C. J. 49, 366).
Needles; gives off CO, when melted.
DI-PHENYL-DI-BUTINYL KETONE

CO(OH:CH:CHPh), [142°]. Formed from colonionioning, laws, rothed from einnamic aldehyde, acctone, and NaOHAq (Diehl a. Einhorn, B. 18, 2825). Needles.

PHENYLBUTINYL METHYL KETONE
CH., CO.CH.CH.CH:CHPh. [68°]. Formed from

sinnamic aldehyde, acetone, and NaOHAq (Diehl a. Einhorn, B. 18, 2821). Plates (from ather). Yields a dibromide [174"] and a phenyl-

sther). Yields a dibromide [174°] and a phenyl-bydrazide [180°] crystallising in plates. DLPHENYBBUTONENE C₁₈H₁₈. Phenyl-naphthalene? [101°]. (846°). Formed from di-oxy-sthyl-benzene (styrolene alcohol) by treatment with H₂SO₂ (16 pts.) and water (9 pts.) Zincke a. Breuer, A. 226, 23). Plates, v. sol. alcohol. Oxidised by K₂Cr₂O₂, and HOAc to C₁₈H₁₈O₂ [110°], which crystallises in golden needles, m. sol. alcohol, and is readily poly-merised by exposure of its solution to light, yielding two polymerides [207°] and [225°-229°]. merised by exposure of its solution to light, yielding two polymerides [2077] and [2265-2229]. The quinone C₁₄H₁₆O₄ is reduced by SnCl₄ to the hydroquinone C₁₄H₁₆O₄D₃ [93°] which gives C₁₄H₁₆OAO₂ [152°]. The quinone C₁₄H₁₆O₄ is reduced by squeous SO₄ at 120° to the quinohydrone C₁₄H₁₆O₄ [138°]. On heating the animone with NaOHAQ it is converted into the cry quinone C₁₄H₁₆O(H)O, [144°], which gives D₁₄H₁₆OAO₂ [111°], and may be reduced to the cry quinhydrone [188°], and the cry quinhydrone [18°]. The oxydininene is suitaised by alkaline KMnO₄ to an acid A₁₄H₁O₄ [177°-197°] whence BaA"2aq, R₂A", OxyGH₁A"6sq, and Ag₄A". Alcoholic NH₂

by water (Popoff, B. 8, 768). Needles.

Tri-pheng-tert-butyl-alcohol CPh, CMe, OH, (above 260°). Formed from CCl. CMe, OH, (benzene, and AlCl. (Willgerode a., Genieser, J. pr. [2] 87, 868). DI-PHENYL-DI-ISOBUTYL-TETRAZONE

C.H.,NPh.N:N.NPh.C.H. [107°]. Got from phenyl-isobutyl-hydrazine in ether by treatment with HgO (Michaelis a. Philips, A. 252, 284).

1062; A. 171, 219). The same hydrocarbon 106§; A. 171, 219). The same hydrocarbon appears to be formed by distilling the lactonic acid of γ-oxy-γ-phenyl-s-di-methyl-succinic acid (Penfield, A. 216, 125). Oil, yielding a liquid dibromide. KNO₂ and HOAc form C₁₀H₁₂N₂O₃, which gives on reduction a base O₁₀H₁₃NO, whence B'HCl and B'₂H₂PtCl₄ (Tōnnies, B. 11, 1211). 1511).

(a) Phenyl-butylene C₄H₁CH:CH.CH.CH.(CH₂CH) (186°). Formed by distilling C₁₆H₁₁Br obtained by bromination of n-butyl-benzene (Radziszawski, B. 9, 260). Forms a dibromide C₁₆H₁₂Br₂ [71°] crystallising in white needles. Probably identical orystallaing in white needles. Frobably identical with the phenyl-butylene (187°) obtained by Perkin (C. J. 33, 567; 35, 140 from phenylangelic acid by successive treatment with Histand Na CO.Aq or with HI and ROLE Perkin's phenyl-butylene corms a crystalline dibromide

phenyl-duylene during a cypesanine during (68°) converted by alcoholic potash into oily C_{1,6}H_{1,1}Br, which forms oily C_{1,6}H_{1,6}Br, (185°). Formed by heating benzoic aldehyde with sodium isobutyrate and isobutyric anhydride for 8 hours with inverted condenser (Perkin, C. J. 35, 138), and by distilling 8-cxy-phenyl-valeric acid (Fittig and by distilling B-CKy-Pnenyi-valence and (Fitting a. Jayne, A. 216, 11d). Oil. Forms an oily dibromide converted by alcoholic potash into C₁₈H₁₁Br, which forms crystalline C₁₈H₁₁Br, (53-5). Yields benzoic and scetic acids en oxidation. Nitrous acid forms C₁₈H₁₈N₂O₈[1127] (Angeli, B. 25, 1962).

DI-PHENYL-BUTYLEHE C. H., 4.6.
C.H., CH.CH.CH.CH.C.H. [39°]. Formed by reduction of the nitrile of e-phenyl-f-styryl-acrylic acid (Freund a. Immerwahr, #. 22, 2858).
Crystals, v. sol' alcohol. Yields a dibsomide [88°].

DI-PHENYL-BUTYLENE-DIAMINE O.H. (NHPh). • Formed from isobutyline dibromide and aniline (Colson, C. R. 105, 1014; Bl. [2] 48, 900). Oil. Yields a nitrosamine [90°].

—B'H.Oi. [98°]. S. 10 at 15°. B'H.Bs. [122°]. S. 10 at 15°; 30 at 100°.

TOPEN IL-DONE CANADADA CPh.NH >C.CH.Pr. [2230]. Formed from benzil, isovaleric aldehyde, and NHAQ (Japp a. Wynne, C. J. 49, 468).—
B"H.PtOl.: orystalline
FHENYL-120BUTYL-HYDRAZINE
C.H.NPh.NH, (240°-245°). Formed from iso-

butyl bromide and sodium phenyl-hydrazine (Michaelis a. Philips, B. 20, 2485; 2. 252, 282; 270, 122). Liquid, which reduces hot Fehling's

solution. Converted by thionyl-aniline into oily C.H.NPh.N:SO.—B.H.SO.: Blates. Acetyl derivative C.H.NPh.NHAc. [114°

PHENYL BUTYL KETONE C.H. CO.CH.Pr. Mol. w. 162. (237°) at 720 mm. Got by boiling propyl-bargoyl-acetic ether with alcoholic potash (Pegkin a. Calman, C. J. 49, 162). Gil. Phenyl isobutyl ketone C.H., CO, CH, Fr.

(228°) at 720 mm. S.G. 175 993. Formed from isopropyl-benzoyl-acetic ether (P. a. C.) and also by distilling a mixture of calcium benzoate and calcium isovalerate (Popoff, A. 162, 153). Liquid. Does not combine with NaHSO. Yields benzoic,

isobutyric, and acetic acids on oxidation.

PHENYL BUTYL RETONE CARBOXYLIC
ACID C.H., CO.CH., CHEL. Co.H. Ethyl-benzoylpropionic acid. [83°]. Formed by heating the
dicarboxylic acid. Small needles.—CaA', aq.

Ethyl ether EtA'. Oil.
Phenyl butyl ketone carboxylic ether C.H. CO.CHPr.CO.Et. Propyl - bensoyl - acetic acid (251° at 300 mm.). Formed from benzovlacetic ether, NaOEt, and PrI at 100° (Perkin a. Calman, C. J. 49, 160). Liquid.

Phenyl isobutyl ketone carboxylic ether C.H. CO.CHPr.CO.Et. (237° at 225 mm.). Formed

in like manner, using isopropyl iodide.

Prenyl butyl ketone dicarboxylic acid

C.H., CO.CH., CEt(CO.H). Benkoyl-ethyl-isosuccinic ether. Got by saponifying its ether, which is formed from sodium-malonic ether and w-brome-scetophenone (Dittrich a. Paal, B. 21, 3463). Organilla mass.—(NH_d)A": amorphous. -KrA": pearly plates, v. sol. water.—CaA" aq.—
Ag.A": plates. Hydrasine salt. [1037].
Phenyl hydraside C.H., N.O., [1227].
PHENYL BUTYL METHYLENE DIRECTORE

C.H. CO.CH. CO.CH. Pr. Valeryl-acetophenone. (184° at 30 mm.). Oil. Got from acetophenone,

isovaleric ether, and NaOEt (Stylos, B. 20, 2181).
PHENYL - BUTYL METHYL KETONE CARBOXYLIC ETHER

CH. CO.CEt(CH.Ph).CO.Et. (c. 297°). Formed from sodium benzyl-acetoacetate and EtI (Conrad, B. 11, 1057).

PHENYL BUTYL OXIDE p. Butyl derivative of PHENOL

PHENYL-ISOBUTYLPHENYL-THIO-UREA C.H.NH.CS.C.H., CH.Pr. [152°]. Formed from C.H., (NH.). CH.Pr. and phenyl-thiocarbimide (Mainzer, B. 18, 2023). Plates, sol. alcohol. DL-PHEFIL-ISORUTYL-QUIFOXALIER

* O.H.(OH.Fr) N:CPh. [144°]. Formed from N:OPh

Bensil and issuitylphenylene-diamine (Gelzer,
B. 20, 8267). Needles, v. sol. alcohol.—B'HCl.
PHENEL-BUTYL-FHIQ-ALLOPHANIC ACID

MIPLOS.N(C,H.).ON. [189°]. Formed from
section systemide, whenyl thiotaxis mide, and isobutyt iedide (Hecht, B. 45, 822). Siender needles, v. al. sol. hot water.

DI-PHENYL-180BUTYL-TRIO-SEMI-CARB-IDE NHPh.CS.NH.NPh(CH.Pr). [140°]. AZIDE NHPh.OS.NH.NPh(Ch. vr). [120].
Formed from phenyl-igobutyl-hydragine and AZIDE phenyl-thiocarbimide (Michaelis a Philips, A. 252, 284). White crystals.

PHENYL-ISOBUTYL-THIO-UREA NHPh.CS.NHC,H, [82°]. Formed from phenylthicoarbimide and isobutylamine (Healt, B. 25, 815). Needles, m. sol. hot water.

PHENYL-BUTYL-THIOHYDANTOIN

CSC NPh.CO (179° uncor.]. Formed by fusing phenyl, thiocarbimide with leucine (Aschan, B. 17, 426). Minute colourless prisms. PHENYL-BUTYRIC ACID C. H. C. i.e. CH.CH.CH.PhCO.H. [42°]. (27°2°). Formed by acconting the nitrile which is made by

by caponifying the nitrile which is made by the action of EtI and solid NaOH on benzyl cyanide (Neure, A. 250, 153). Crystalline Methylether Med. (228°).

Nitrile PhOHEt.ON. (245°).

Phenyl-n-butyric acid

7-range-reserved to the control of t acid by protracted treatment with sodium-amalgam (Jayne, A. 216, 107). Long flat plates

(from water).—CaA',: amorphous mass.

Phenyl-isobutyric acid CH,Ph.CHMe,CO.H. Bensyl-methyl-acetic acid. [87°]. (272°). S. ·81 at 15°.

Formation .- 1. By heating benzyl-methylmalonic acid (Conrad, B. 13, 598).—2. By heating benzyl-methyl-acetoacetic ether with cone. KOHAq.—3. By reduction of the phenylcrotonic acid obtained from benzoic aldehyde. sodium propionate, and propionic anhydride .-4. By reducing phenyl-angelic (methyl-cin-namic) acid with sodium-amalgam (von Miller, B. 23, 1888).

Properties .- Plates. Converted by H.SO, at 150° into oxy-methyl-indonaphthene.

Salt .- AgA'. S. 248 at 20°.

Ethyl ether Eth'. (287°). S.G. 11 Oil (Conrad a. Bischoff, A. 204, 177). Bensyl ether C.H.A'. (820°-528°). S.G. # 1.05.

18 1 046. A product of the action of sodium on benzyl propionate (Conrad a. Hodgkinson, A. 193, 312).

Amide CH.Ph.CHMe.CONH. [100°]. Formed by heating the NH, salt (Edeleano, B. 20, 618). Needles, v. sol. alcohol and ether.

Di-phonyl-butyric acid CH.Ph.OMePh.CO.H. [128°]. Got from its nitrile, which is obtained from a-phenyl-pro-pionitrile and benzyl chloride (Janssen, 4. 250, pionitrie and benzyl chiorine (sanseen, A. 200, 187). Needles, v. sol. ether and alcohol. NaA'7aq: long thin needles,—CaA',—BaA',—CuA'. [78°].—AgA': white insoluble powder. Nitrile O₁H₁₈ON. (887°). Oil.

Isomeride v. Di-Beneyi-Acetic Acid.

References. - Brome, Nitro. Nitro-Amino, and Oxy. Menyi-Butter Acid.

PHENTI-ISORUTTER ACID.

OH, OH(OH,Ph).OHO. (227°). Formed by distilling the corresponding lime salt with calcium formate (Miller a. Rohde, B. 23; 1080). Oil.

PHENYL-BUTYRIC-CARBOXYLIC ACID.

γ-PHENYL-BUTYRIC-o-CARBOXYLIC ACID THE TILE UTTRICE-CARBOXILIO ACID

C1H19O, i.e. C.H4(CO.H).CH.CH.CH.CH.CO.H.

[189]. Formed by heating at 180°-190° the

double-lactone of benzoyl-propionic-o-carboxylic

acid C.H4(CO.O) CCCH2 CH4 with HI

and P (Roser, B. 18, 8118). Small plates.

V. sol. alsohol, sl. sol. cold water.—A"Ba: very

subblem water. soluble in water.

PHENYL-BUTYRO-LACTONE v. Lactone of OXYPHENYL BUTYBIC ACID.

PHENYL-CACODYL v. vol. i. p. 320. PHENYL-CAMPHORAMIC ACID v. CAM-

PHORIC ACID.

PHENYL-CAMPRYL-THIO-URBA *v. CAM-PHYL-THIO-URBA.

PHENYL CARBAMATE NH2. CO.Ph. [148°]. FRIENTL UARBANATFNH, CO, Ph. [148°]. Formed by the action, in ethereal solution, of NH, on ClCO, Ph or of NH, COCl on phenol (Kempt, B. 2, 740; Gattermann, A. 244, 43). Formed also, together with Et, CO,, by heating phenyl ethyl carbonate at 300° (Bender, B. 19, 2268). Needles (from water), sol alcohol and ether. Decomposed by NaOHAq into NH₃, phenol; and Na₂OO, NH₂Aq at 150° forms phenol and uses.

PHENYL-CARBAMIC ACID NHPh.CO₂H.

Carbanilic acid. The ethers of this acid are got by the action of aniline on the chloroformic ethers Cl.CO.OR, and also by the action of phenyl cyanate on alcohols. They are decomposed by potash into CO₂, aniline, and alcohols.

Acetyl derivative NPhAc.CO.H. The Na salt is formed by passing CO₂ over sodium acetanilide in the cold (Seifert, B. 18, 1358). It is decomposed by water into acetanilide and NaHCOs. By heating at 140° under pressure it is converted

into NPhH.CO.CH, CO.Na.

Methyl ether NHPh.CO.OMe. [47°] (Hentschel, B. 18, 978). Prisms. Converted by HNO, (S.G. 1-48) into C,H,(NO₂),NH.CO₂Me [127²] and [6;42:1]C,H,(NO₂),NH.CO₂Me [127²] (Van Romburgh, R. T. C. 10, 185). H₂SO, torms SO₂H,C₂H₂NH.CO₂Me which is converted by horse size of the No. 1985. by bromine into c.H.Br.NH.Co.Me [96:5°] (Hentschel, J. pr. [2] 34, 423). Distillation with lime at 260° gives aniline, methyl-aniline, di-methyl-aniline, and di-phenyl-urea (Nölting, B. 21, 8154).

Ethyl ether NHPh.Co.et. [52°]. (238°) (Wilm a. Wischin, C. J. 21, 192). Formed as above and also by boiling the product of the action of phenyl-urea on aceto-acetic ether with conc. HCl (Behrend, A. 233, 6) and by the action of sodium acetanilide on chloro-formic action of sodium acetanilide on chloro-formic ether (Paal a. Otten, B. 23, 2590). Needles (from water). Not affected by boiling conc. HClAq, but decomposed by HClAq at 150° into CO, aniline, and EtCl. Boiling alcoholic KOH gives aniline and K_cCO_s. Yields a bromoderivative [81°], a di-nitro-derivative [110°], and, a tri-nitro-derivative [144°]. When distilled with NaOPh at 220° it gives phenol and diphenyl-ures [235°] (Hentschel, J. pr. [2] 27, 438). — NKPh-CO_Et. Formed by dissolving phenyl-carbancie ether in alcoholic potash. phenyl-carbagic ether in alcoholic potash. Hygroscopic needles, decomposed by water.

wards with conc. KOH it yields NPh CH CH [124°], which is converted by HClAq at 170° into chloro-ethyl-aniline.

chioro-etnyi-anima.

Ethylene ether C.H.A". [158°]. Formed from ethylene glycol and phenyl cyanate (Snape, B. 18, 2430; C. J. 47, 73). Prisms.

Propyl ether PrA'. [59°]. Slender needles, v. sol. sloopol (Rômer, B. 6, 1101).

v. sol. alcohol (Römer, B. č. 1101).

Isopropyl ether PrA'. [90°] (Gumpert,
J. Jr. [2] 81, 119; 32, 278); [48°] (Spica,
G. 17, 165). Needles (trom dilute alcohol).

Di-chloro-propyl ether (Otto, J. pr. [2]
44, 22) CH.Cl.CH.Cl.CH.A'. [74°]. Prisms.

Isobutyl ether C.H.A'. [80°]. (216°).

Needles, v. sol. alcohol (Mylius, B. 5, 972).

Hepterbyl ether C.H., A'. [85°]. Formed
by the action of phanyl ayanate and he heptenyl
alcohol got by reducing suberone (Markownikoff,
C.R. 110, 466). Prisms (from alcohol).

Giyceryl ether & GIYCERYL-TRI-PHENYL-

Glyceryl ether & GLYCERYL-TRI-PHENYL-

TRI-CARBAMATE.

Phenyl ether NHPh.CO.Ph. [126°]. Formed from phenyl cyanate and phenol (Gumpert; cf. Hofmann, B. 4, 249). Needles (from benzene). With NH Aq it forms phenyl-urea.

Phenylene ethers. Theo [165°], m[164°], and p [207°] compounds are got by heating pyrocatechin, resorcin, and hydroquinone respectively

with phenyl cyanate (Snape, B. 18, 2428).

Phenylphenyl ether C.H., C.H., A'.

[110°]. Formed from p-amido-diphenyl and ClOo_Et_(Zimmermann, B. 18, 1965).

(a)-Naphthyl ether C, H,A'. [178:5°]. Slender needles (Leuchart a. Schmidt, B. 18, 2340; Snape, C. J. 47, 776). Decomposed by [178.50].

 (β) - Naphthyl ether C₁₀H₁A'. [230°].
 (L. a. S.); [155°] (S.). Thick prisms. The tetrahydride C₁₀H₁O.CONPhH [98°5] is formed from (B) naphthol ac-tetrahydride and phenyl cyanatè.

phenyl cyanate.

Di-phenyl-carbamic acid.

Chloride NPh. CGCl. [85]. Formed from COCl. and diphenylamine in CHCl. (Michler, B. 9, 396). White scales (from alcohol).

Ethyl ether NPh. CO.Et. [72]. (above 360°). Formed by heating diphenylamine with ClCO. Et (Merz a. Werth, B. 6, 1511; Hager, B. 18, 2573). Leave prime (from beneze).

Phenyl ether* PhA'. [104*]. Formed from the chloride and KOPh (Lellmann a. Bonhöffer, B. 20, 2122). The compound C,H,(NO2)A [1147], made in like manner from o-nitrophenol, may be reduced to C,H,(NH-)A' [1912]. The mand p-nitrophenyl ethers [90°] and [116°] yield m- and p-amido-phenyl ethers [133°] and [146°] (Lellmann a. Benz, B. 24, 2111).

**PoTolyl-ether C,H,A'. [81°]. (L. B. B.). References.—Amido., Bromo., Dr. Bromo. Nitro., Nitro., Nitro. Mitro., Nitro. Oxy., Oxy., OXY-AMIDO-, and NITRO- PHENYL-CARBANIC ACID

and ETHER.

PHENYL CARBAMINE C.H.NO. Mol. w. 103. (167°). S.V. 121.6 (Lossen, A. 254, 78). Formed by distilling aniline with chloroform and alcoholic potash (Hofmans, A. 144, 117). Stinking liquid, quickly decomposed by acids Chloro-ethyl ether

Chloro-ethyl ether

and alcoholic potash (Hofmans, A. 144, 117).

NHPh.CO.CH.CH.Cl. [51°]. Formed from

aniline and Cl.CO.CO.H.Cl (Nemirowsky, J. pr.

[3] 31, 174; Otto, J. pr. [3] 44, 15). Needles,

sl. sol. hot water. When boiled alone and after
(Weith, B.8, 210). Yieldsphenyl-thiocarbindide

en heating with sulphur. Mixed with propionitude and ether, it yields, by successive treatment with sodium and water, the compound CPh(NH).CHMe.CN [97°] (Von Meyer, J. pr. [2] 89, 189).

Chloride NPh.CCl. (212°). Formed from phenyl-thiocarbimide and Cl (Sell a. Zierold, B. 7, 1228). Pangent liquid, with nasty smell, yielding s-di-phenyl-urea when heated with

water at 100°

PHENYL-CARBAZIC ACID. The or stal-a calt N.H.Ph.CO.ON.H.Rh is formed by the line salt N.H.Ph.CO.ON.H.Rh is formed by the action of CO. on phenyl-hydrazine and water. It is deliquescent, and sl. sol, water and ether (Fischer, A. 190, 124).

Methyl ether NHPh.NH.CO, Me. [117°].

Methyl ether NHPh.NH.CO₂Me. [117°].
Short prisms (Heller, A. 263, 281).

Ethyl other NHPh.NH.CO₂Et. [87°] (F.) ?

[82°] (N.) Formed from phenyl-bydrasine and ClCO₂Et (E. Fischer, B. 22, 1936), or AcC(CO₂Et)₂ (Nef, A. 266, 107). Needles. Ac₂O forms C₄H.N.HAc.CO₂Et [108°] (H.).

PHENYL-semi-CARBAZIDE C.H.N.O i.s.
NHPh.NH.CO.NH. [172°]. Formed from potessium cyanate and phenyl-hydrazine hydrochloride (E. Fischer, A. 190, 113; Freund, B. 21, 2463). Formed also by heating phenyl-hydrazine hydrochloride (1 mol.) with urea (2 mols.) at 160° for 4 hours (Pinner, B. 20, 2358; mols.) at 160° for 4 hours (Pinner, B. 20, 2358; 21, 2329) and by heating di-phenyl-carbazide with urea (Skinner a. Ruhemann, C. J. 53, 550; B. 20, 3378). Prisms, v. sol. hot water. Yields di-oxy-phenyl-triazole [263°] on heating with urea. By heating at 160° it is converted into displenyl-urazine C_{1,}H_{1,}N₁O₂ [264°] and other products. COCl₂ forms C₄H₁N₁O₂ [167°].

Bensoyl derivative NPhBz.NH.CO.NH₄.

[203°]. Formed from benzoyl-phenyl-hydrazine cyanate (Michaelis as Schmidt, A. 252, 317).

Dr-phenyl-semi-carbazide

C.H.NH.CO.N.HPh. [173°]. Formed from phenyl-hydrazine by combination with phenyl phenyl-hydrazine by combination with phenylyanate; and also by heating phenyl-hydrazine
with phenyl-urea (Kühn, B. 17, 2881; Skinner,
C. J. 58, 552). Acedles or plates (from alcohol
or benzene), sl. sol. water. GOCl₂ in benzene
forms C₁₄H₁₁N₂O, [178°] (Freund, B. 21, 2465).
Di-phenyl-carbaside CO(N,H₂Ph), §151°]
(S. a. K.); [164°] (E. Fischer, B. 22, 1930).
Formed by heating phenyl-hydrazine (2 mols.)
with carbamic ether (1 mol.) (Skinner a. Ruhe-

with carbamic ether (1 mol.) (Skinner a. Ruhe mann, C. J. 58, 550; B. 20, 3372). Formed also from phenyl-hydrazine and COCl₂ (Heller, A. 963, 277). Crystalline. Forms with HgCl₂ a crystalline compound B'HgCl, not melted at 136°. Alcoholic potash forms a red solution containing di-phenyl-carbasone N2H2Ph.CO.N:NPh crystallising in orange needles [157°]. Benzene and CSCl, form CS NPh.N C.N; NPh (176°)

(Freund a. Kuh, B. 23, 2833).

PHENYL-CARBIMIDE v. Phenul isocuanate.

vol. ii. p. 815. . DI - PHENYL - DI - CARBINIDO - TETRA - p -AMIDO-TETRA-TOLYL-DI - o-SULPHIDE

PhN:C NH.C.H., S.C.H., NH C:NPh. Di-thiop-tolyl-di-phenyl-di-quanddine. [c. 119°]. Formed by heating di-thiocarbonyl-tetra-amido-tetra-dolyl-di-sulphide with aniline and HgO (Truhlar, B. 20, 674). Amornhous; v. sol. alcohol.

DI-PHENYL-CARBINOL C_{1.}H., O i.e. Ph., CH(OH). Benshydrol. Mol. w. 184. [68°]. Ph. On Oct. 100 p. 100 amalgam (Linnemann, A. 188, 6; Beckmann, B. 22, 915); or by heating bengophenone with zine and alcoholic KOH (Zagumenny, A. 184, 174). Slender silky needles, v. e. sol. alcohol and ether. Converted into bensophenone by oxidation with chromic acid. Bromine forms a dibromo-benzhydrol [163°]. Zn and HOAc form benzpinacone. Zn and HCl in acetic acid Zn and HOAc

tillation contly resolves benzhydrol into water and benzhydrolic efter. P.S. forms C₂,H₂₁(SH)₂ [161°] and oily Ph₂OH(SH) (Engler, H₂, 11, 922). Ethyl derivative C₁₁H₁₁OEt. (288°). S.G. ²⁰ 1·03. From benzhydrol, alcohol, and H₂SO₄, or from Ph₂CHBr and alcoholic KOH (Friedel a. Balsohn, Bl. [2] 33, 389). Liquid.

soletion reduce it to tetra-phenyl-ethane. Dis-

Isoamyl derivative C₁,H₁₁,OC₂H₁₁, (810°).

Chloride Ph.CHCl. [14°]. From benzhydiol and HCl (Engler a. Bethge, B. 7, 1128).

Bromide Ph₂CHBr. [45°]. From di-phenylmethane and bromine at 150° (F. s. B.). Water at 150° decomposes it into benzhydrol and benzhydrolic ether. Conc. NH,Aq forms mono-and di-benzhydryl-amine (Friedel a. Balsohn, Bl. [2] 33, 587).

Acetyl derivative Ph₂CH.OAc. [42°]. (302°). S.G. 22 1·49. Prisms, v. sol. alcohol, acetic acid, and ether (Vincent, Bl. [2] 85, 304). Bensoyl derivative Ph₂CH.OBz. [89°]. Non-volatile. Trimetric, a:b:c=1: 477: 668.

Succinyl derivative

(Ph_CH.O)₂.O₂.O₂.O₂.H., [142°]. Gives, on distillation, succinic acid and benzhydrolene C₁₂H₁₄. [210°].

Anhydride CaH200 i.e. Ph20-CPh2(?)

[111°]. (315°) at 745 mm. From benzhydrol by long boiling with water or by treatment with PCl₂, BzCl, or diluted H₂SO₄. Monoclinic crystals (from benzene). Reduced by zinc and HCl in HOAc to tetra-phenyl-methane (Zagumenny, J. R. 12, 431). Zinck® a. Thorner (B. 11, 1398) obtained this anhydride by heating benzpinacone, $C_{2x}H_{2x}O_{2x}$, and consequently assume the formula $C_{2x}H_{2x}O_{2x}$.

References .- DI-AMIDO-, DI-BROMO-, and OXY-

DI-PHENYL-CARBINOL

Tri-phenyl-carbinel C, H, O i.s. CPh. OH.

Mol. w. 260. [159°]. (above 860°). Formation. — 1. By boiling tri-phenylmethane with chromic acid mixture (Hemilian, B. 7, 1203).-2. From CPh.Br and water.-3. By the action of water on CPh₂Br and water.—8.
By the action of water on CPh₂Cl got from
AlCl₂, benzene, and CCl₃, or CCl₂COCl (Friede
a. Crafts, A. Ch. [6] 1, 499; Hentschel, J. pr.
[2] 86, 311).—4. By heating its dicarbaxylic
acid with baryta (Hemilian, B. 19, 3073).

Properties.—Six cided plates — 11.

Properties.—Six-sided plates, v. sol. alcohol.

Acetyl derivative CPR, OAc. [99°]. Acetyl derivative Prisms (Allen a. Kölliker, A. 227, 116).

Methylether CPh.OMe. [82°]. Lamine. Ethylether CPh.OEt. [72°] (F. s. C.);

[83°] (A. a. K.). Chloride v. Chloro-tri-phenti-methams.

DI-PHENTL-GARRINGL CARBOXYLIC | ACID O. OXY-BENEYL-BENZOIC ACID.

AUD c. ONE-BENEYL-BENZOIC AUD.

Di-phesyl-earbinel dicarboxylic acid

CH(OH)(O,H,&O,H), Formed by heating
benzil di-o-carboxylic (diphthalylic) acid with

KOHAq (50 p.c.) at 180° for 5 minutes (Graebe
a. Juillard, 4. 242, 238). The acid splits up at

the moment of liberation into water and anhy.

dride.—BaA"aq.

Anhydrids C_{1,}H₁₀O₄. [203°]. S. 022 at 23°. Formed as above, and also by reducing benzophenone di-o-carboxylio acid. Monocilinic crystals (from alcohol). On heating, it yields a white sublimate [172°] reconverted by treatment with NaOHAq and HCl into the original anwith Neuthal and stul into the engine an-hydride. Phenyl-hydrazine gives O_2H_1N,O_2 . H_2SO_4 and HNO_2 give $C_2H_4(NO_2)_2O_1$ [c. 275°], which forms EtA' [148°].— $Bg(O_1H_1O_1)_2$ [aq. — OuA'_4 Saq.— AgA'_4 — C_1H_2 MeA'. [155°].— EtA'_4 . [100°].— $C_1H_2O_4(NH_2)_4$. [160°]. Needles. •

Isomeride v. Oxy-BENZYL-ISOPHTRALIC ACID. Di-phenyl-carbinol tri-carboxylic acid

O(OH)(CO,H)(C,H,,CO,H), Anhydrids Cl.H1,Oo. [170°]. Formed by heating benzil dio-carboxylic acid with MaOHAQ (4 p.c.) at 112° for 8 minutes (G. a. J.). Minute crystals, sl. sol. cold water. Gives off CO₂ on oryseas, s., sol. cold water. Gives on CO₂ on heating, yfelding the anhydride of di-phenyl-carbinol dicarboxylic acid.

Ethers of the anhydride Me,A". [148°].

—Et_A". [108°]. Prisms, v. sol. alcohol.

Tri-phenyl-carbinol.o-carboxylic acid *OPh,(OH).C.H..CO.H. The Na salt is formed by heating di-phenyl-phthalide with NaOHAq. but the acid splits up on liberation into water and its anhydride, di-phenyl-phthalide (Baeyer, A. 202, 50).

Tri - phenyl - carbinol m - carboxylic acid. [162°]. Formed by oxidation of di-phenyl-m-tolyl-methane with CrO, and HOAc (Hemilian, B. 16, 2369). Trimetric plates.

Tri-phenyl-carbinol p-carboxylic acid (?). [187°]: Formed by oxidation of CHPh, C.H. CHO (Oppenheim, B. 19, 2028) or of di-phenyl-tolyl-methane (Hemilian, B. 7, 1210). Needles.—
BaA'₂7aq. Needles, v. sl. sol. cold water.
Tri-phenyl-carbinol dicarboxylic acid. An-hydrids CPh. Co.—CO.

Di-phenyl-phthalide carboxylic acid. [246°]. Formed by oxidation of di-phenyl-y-xylyl-methane, di-phenyl-tolyl-methane o-carboxylio acid, di-phenyl-tolyl-carbinol m-carboxylic acid, or di-phenyl-methyl-phthalide (Hemilian, B. 16, 2372). Crystals, v. sol. alcohol and HOAc. Yields benzophenone and terephthalic acid on fusion with potash. Zinc-dust and NaOHAq reduce it to tri-phenyl-methane dicarboxylic acid.

Tri-phenyl-carbinol dicarboxylic acid $C_{\eta,H_1}O_1$, ϵ . $CPh_{\eta}(OH)_{\tau}C_{\eta,H_2}(OO,H)_{\tau}$ [1:3:4]. [180*]. Formed by oxidation of di-phenyl-xylyl-methane with K.Cr.O, and H.SO.Aq (Hemilian, Bs.19, 8072). Needles (from water), v. e. sof. alcohol. On jusion it yields an amorphous anhydride $C_{\eta,H_1}O_{\tau}$. On fusion with $B_{\eta}(OH)_{\tau}$ it forms tri-phenyl-carbinol.—Ag.A": pp. Tri-phenyl-carbinol dicarboxylic soid $CPh_{\tau}(OH)_{\tau}CH_{\tau}(OH)_{\tau}$. [12:24]. Anhydride Tri-phenyl-carbinol dicarboxylic acid

QPh_(OH, O,H,(OO,H), [1:2:4]. Anhydride C_nH,O. Di-phonyi-phthalide carboxylic acid. [228]. Formed by oxidation of the correspond-

ing di-phenyl-xylyl-methane (H.). Tables (coning di-phenyi-xylyi-methane (m.). Issues tout-taining EtOH)....Cah', 3aq....Agh': needles. DI-PHENYI-CARBINYLAMINE C13H12N i.e.

OHPh, NH. Benshydrylamins. Exo-amido-di-phenyl-methane. (289°). Formed, together with tetra-phenyl-di-cathinyl-amine, by leaving benzhydryl bromide, CHPh.Br. with conc. NH.Aq for 48 hours (Friedel a Balsohn, Bl. [2] 33, 587). Got also by reducing benzophenone oxim in alcoholic solution by sodium-amalgam and accetic acid (Goldschmidt, B. 19, 3233).

Properties.—Albaline liquid, absorbing CO. from the air.

Salts.—B'Hcl: [270°]; long needles, sl. sol.

Salts.—B'HCl: [270°]; long needics, si. soi. cold water.—B',H,PlCl, 2aq: lancet-like needles (L. a. B.); B'H,PtCl, aq (G).—*B',H,CO, [91°]. Formyl derivative Ph,CH,H,CHO. [182°]. (860°). Formed, almost quantitatively, by heating benzophenone with ammonium formate at 200°–220° (Leuchart a. Bach, B. 19, 2129).

Urea Ph,CH,NH,CO,NH, [143°] (J. a. B.).

Tatra_nhanvl_di_cashinvl_amina(Ph,CH),NH.

Tetra-phenyl-di-carbinyl-amine (Ph.CH),NH. [136°]. Prepared as above, crystallises from alcohol in slender needles, not affected by MeI or AcCl at 100° (F. a. B.).

Tri-phenyl-carbinyl-amine CPh, NH, [103°] TTI-phenyl-carbinyl-amine CPh, NH, [103°]. Torned by passing dry NH, through a solution of CPh, Br in benzene (Hemilian a. Silberstein, Bl. [2], 43, 118; B. 17, 741; cf. Nauen, B. 17, 442). Needles, sl. sol. cold alcohol. Yields B'HCl, B'H.PtCl, 7|aq, CPh,NHWE [73°], CPh,NHCH,Ph [110°], and the acetyl derivative CPh, NHAo [208°]. Forms a crystalline oxalate [253°] (Elbs, B. 17, 701). and the compounds C. H. NRE, R'I. and 701), and the compounds C1.H1, NBr2, B'I2, and B',I,

PHENYL-CARBINYL CHLORIDE v. CHLORO-TRI-PHENYL-METHANE.

TRI-PHENYL - CARBINYL - MAIONIC TRI-PHENYL - CARBINYL - MAIONIC THER CPh., CH(CO_Ett_ [33859]. Gof from sodium malonio ether and CPh., Br (Henderson, B. 20, 1014). Needles (from alcohol).

TRI-PHENYL CARBINYL SUTPHOCYANIDE CPh., NCS. [1379]. Formed from CPh., Br and ammonium sulphocyanide Elles, B. 17, 700).

TRI-PHENYL - CARBINYL - TOLUIDINE CPh., NHO, H., The o [1429] and p [1779] compounds are formed from CPh. Br and o and p

pounds are formed from CPh,Br and o and p toluidine respectively (Elbs, B. 17, 706). The p- compound yields a crystalline nitrosamine [1450_1480].

PHENYL-CARBIZINE. Formyl derivative C.H.N (N.CHO). [72°]. (256°). Formed by the action of COCl, in benzene on the phenyl-hydrazide of formic aldehyde (Freund, B. 21, 1240, 2458). Needles (from CS.), ... sol. alcohol and ether. Decomposed by boiling Na CQ.Aq into CO, and the phenyl-hydrazide of formic aldehyde.

Acetyl derivative CO (280°). Formed in like manner from acetic aldehyde. Monoclinic prisms; a:b:c=1.210:1:1:557; $\beta=73^{\circ}23'$.

Propionyl derivative. [68°]. Needles. Bensoyl derivative CO NPh. [114°]. Meedles (from alcohol) or plates (from HOAc), PHENYL CARBONATES.

Phenyl-sarbonic acid *6.H.O.CO.H.

Boldium sail PhO.CO.Na. Prepared by treating dry sodium phenylate in the cold for a mouth with CO, until it has taken up the calculated quantity of the gas. The product is a very hygroscopic powder.

hygroscopic power.

Reactions.—1. With water it gives off half its CO_2 in gaseous form: $2\text{PhO.CO.Na} + \text{H.O} = \text{PhONa} + \text{PhOH} + \text{NaHOO.} + CO_2 - 2$. At 12^{10} ts splits up into CO_2 and PhONa = 3. Heated rapidly to $180^{-2}.200^{\circ}$ it gives off smaller quantities of CO, together with phenol, the regidue being sodium salicylate. -4. In a sealed sube at 120°-180° for several hours it changes completely to sodium salicylars: C₄H₂O.CO₂N₀ = C₃H₄(OH)CO₂N₀ (R. Schmilt, J. pr. [2] 31,

108).
Di-phenyl carbonate C₁₂H₁₀O₂ i.e. CO(OPh)₂.
78°] (Kenpf. J. pr. [2] 1,404; Hentschel, J. pr. [2] 27,41; 36, 315); [88°] (Richter, J. pr. [2] 27,41). (303°). Formed by passing COCl₂ into in aqueous solution of NaOPh, or into phenol ontaining AlCl₂. Formed also from ClCO₂CCl₂, henol, and AlCl₂. Needles (from alcohol)* (leoholic potash forms phenol and K.CO₂. VaSEt gives NaSPh and (EtS)₂CO (Seiffert, J. pr. [2] 31, 464).

References.—Di-Bromo-*and Nitro-*phenyl.**

DIPHENYL o-CARBOXYLIC ACID C₁₁H₁₀O₂
i.e. C₄H₃,C₄H₄,CO₃H [1:2]. Phenyl-benzoic acid.
Mol. w. 198. [111²]. Formed by potash-fusion from diphenylene ketone (Fittig a. Ostermaier, B. 5, 933; A. 166, 374; Schmitz, A. 193, 115). Formed also, together with diphenylene ketone oxide, by distilling sodium salicylate with triphenyl phosphate (R. Richter, J. pr. [2] 28, 305). Small needles (from hot alcohol), m. sol. hot

Small needles (from hot sleohol), m. sol. hot water.—KA'aq.—BaA',aq.—CaA',2aq.—AgA'.

Ethyl ether Eth'. (300°-305°).

Teorahydrida C.H.,C.H.,e.Co.H. Phenylhexamethylene carboxylk acid. [405°]. Formed
by heating the corresponding dicarboxylic acid,
and by the higdrolysis of phenylhexamethylenyl
methyl ketone carboxylic ether (Kipping a.
W. H. Perkin, inc. C. J. 57, 319). Rosettes of
crystals (from ligroin).—AgA': amorphous pp.

Bibhenyl m. sarboxylic acid.

Diphenyl m carboxylic acid C.H., C.H., (Co.H. [161°]. Formed by exidation by chromic acid and HOAc from [1:3] C.H.Ph., from C.H.PhMe, and from C.H.Ph.CH.Br (Schmidt a. Schultz, A. 203, 132; Adam, A. Ch. [6] 15, 243). It is also a product of the fusion of benzoic acid with potash (Barth a. Schreder, M. 8, 808). Leaflets (from alcohol), sl. sol. water. Yields isophthalic acid on oxidation.— NaA', 2aq.—CaA', 3aq.—BaA', 3aaq: needles.—

Bad', 43aq.

Ethyl ether EtA'. (above 360°). Oil.

Diphenyl p-carboxylic acid C.H., C.H., CO.H., [219]. Formed by saponification of its nitrile, which is got by heating potassium diphenyl sulphonate with KCy in a current of dry CO. (Doebner, A. 172, 109). Formed also by oxidation of [13] C.H.Ph. or [1:4] C.H.PhMe (Schultz, A. 274, 213; Carnelley, C. J. 87, 713). It is also a product of the fusion of benzoic said with potent. Tafts of needles (from alcohol), r. al. sol. hot water. May be sublimed. Yields

terephthalic acid on oxidation—Bah',—Cah', Mthyl ther Eth'. [46°]. Prisms. Mitrile CisH., ON. [85°]. Crystajs.

Anilide G. H., CO.NHPh. [224°]. Got by heating C. H., CONOH. C. H., with HOAc, Ac, O, and dry HOl at 100° (Koller, M. 12, 503).

Diphenyl dio-carboxylic acid C. H., O, i.e. [2:1]CO.H.O.H., C.H., CO.H.[12]. Diphenic acid. Mol. w. 242. [228°]. Formed by the oxidation of phenanthraquinone or phenanthrene (Fittig a. Ostermayer, A. 166, 361; Schmitz, A. 198. 116). It is also produced when phenanthra-quinome is boiled with conc. alcoholic potash (Anschutz a. Schultz, A. 196, 50 208, 97). Plates or prisms, m. sol. hot water. May be sublimed. By exhaustive chlorination with SbCl. it rields perchloro-diphenyl, together with a small quantity of perchloro-benzene (Mers a. Weith, B. 16, 2872). Distillation over with red-hot CaO yields diphenylene ketone; distillation with Ca(OH)₂ gives diphenyl.

Salts.—BaA"aq: v. sol. water.—CaA" 2;aq.

-MgA'4aq.—AgA'': bulky white pp.

•Methyleethers Me₂A''. [73:5°].—MeHA''.

[110°]. Plates, m. sol. water. Got by boiling the anhydride with McOH.

Ethyl ethers Et, A". [42°]. Crystals, insol. A. (Hummel, A. 193, 128).—EtHA". [88°]. Anhydride C.H.CO O. [213°]

Formed by boiling the acid with AcCl or Ac.O Assolutz, B. 10, 1884; 13, 1802: Graebe, B. 20, 848; A. 247, 261). Needles, insol. water, sol. alcohol. Decomposed by heat into CO₂ and diphenylene ketone. H.SO, at 100° forms diphenylene ketone carboxylic acid [217°]. Phenyl-hydrazine forms the crystalline compound CO₂H.C₂H₄.C₄H₄.CO₂N₂H₄Ph [174° cor.] which at 250° yields C₄H₄.CO₂N.NHPh [150°]. Benzene and AlCl, form an acid [148°].

Chloride C_{1.}H_e(COCl)₂. [98°]. Formed from the anhydride and PCl₃. Yields di-oxyphenanthrene on reduction.

dmide C₁₂H_a(CO.NH₂)₂. [212°]. Formed

by warming the imide with cone. NH₂Aq.

Amic acid C₁₂H₂(CO₂H)(CONH₂). [193°].

Got by boiling the anhydride with NH₂Aq.

Plates (from alcohol). Converted by heat into the imide.

Imide C.H. CO NH. [2202]. Formed as above, and also by the action of conc. HClAq on the mono-oxim of phenanthraquinons (Wegerhoff, A. 252, 18). Needles (from alcohol), Yields an acetyl derivative sl. sol. hot water. [92°], and forms C14H.O2(NNa), C14H.O2(NAg),

and C_{1.}H₂O₂(NMe).

Diphenyl om-dicarboxylic acid [2:1]CO,H.C,H.,CO,H.[1:3]. Isodiphents. acid. [216°]. Formed by fusing diphenylene ketone carboxylic acid with potash (Fittig a. Lieppmann, B. 12, 163; A. 198, 155; 200, 9). Reedles (from hot water). Yields diphenylene Isodiphenia. ketone on heating with lime. Gives isophthalic

ketone on heating with lime. Gives isophthalic acid on oxidation with CrO₂.—BaA" 6aq. Crystalline.—CaA" 2aq.—Ag,A": pp., al. sol. hot wateg. Mathy l either Me,A". [69-50]. Ethy l either Et,A". Thick bil. Diphenyl op-di-carboxylic acid [2:1] CO,H.O,H.,C,H.,CO,H.[1:4]. [252°]. Formed by saponification of its nitrile [158°] which is got by Sandmeyer's reaction from op-di-amido-diphenyl (Reuland, B. 22, 8018).

Bishenyldi-m-earboxyfic seid. [above 840°]. | forms (C.H.,SO,C.H.),NH.—7. Alcoholic KHS rmed by the action of nitrous acid on di-p-ido-diphenyl dicarboxylic acid (Griess, B. | Phenyl chloro-ethyl anlphone Formed by the action of nitrous acid on di-p-amido-diphenyl dicarboxylic acid (Griess, B.

amido-diphenyl dicarboxylic acid (Griess, B. 21, 982). Small needles, almost insol. cold water.—Bah" Baq ; crystalline aggregates.

Diphenyl di-p-earboxylic acid
[4:1] CO,H.O,H.,C.H.,CO,H.[1:4]. Formed by saponification of its nitrile, and also by oxidation of p-ditolyl (Doebner, B. 9, 129, 272; A. 172, 109). Amorphous powder, nearly-insol. most solvents.—Cah"; insoluble pp.—Bah".—Ar,A'", white np.

Ag₂A": white pp.

Ethyl ether Et,A". [112°]. Prisms.

Nitrile C,H,(CN). [234°]. Formed by heating potassium diphenyl diswiphonate with KCy. Needles (from alcohol)

Diphenyl dicarboxylic acid a C₄H₄,C₆E₄(C₀,H₄), [1:3:5]. [c. 310°]. Formed by heating benzoic aldehyde with CH₂,CO.CO₂H and baryta-water (Doebner, B. 23, 2381 • 24, 1750) 'Orwatals v. al. sol. cold HeAc. Yields 1750). Crystals, v. sl. sol. cold HOAc. Yields diphenyl on distillation with lime.—BaA"4}aq: needles.-CsA".-CuA".

Diphenyl tricarboxylic acid C_{1.}H₁₀O₆ i.e. CO₂H.C₂H₁,C₆H₁(CO₂H)₂. Formed by fusing diphenylene ketone dicarboxylic acid with KOH (Bamberger a. Hooker, B. 18, 1035; A, 229, 169). White crystalline powder, v. sol. alcohol and ether, sl. sol. hot water.—Pb,A'''2: insoluble crystalline pp.—Ag, A", white pp.

References.—Amido-, Bromo-, Iodo-, Nitro-,

and Oxy- DIPHENIC and DIPHENYL CARBOXYLIC ACIDS.

PHENYL-CETYL-AMINE v. CETYL-ANILINE. PHENYL-CHELIDAMIC ACID v. CHELI-

DONIC ACID PHENYL-CHLORO-ACETIC ACID v. CHLORO-

PHENYL-ACETIC ACID PHENYL CHLORO-BENZYL KETONE

C.H.,CO.OHCI.C.H., [65°]. (Curtius, J. pr. [2] 44, 547). Formed by reducing phenyl dichlorobenzyl ketone with iron and acetic acid (Lashovitch, B. 17, 1163). V. sol. alcohol.

Phenyl di-chloro-bensyl ketone C.H., CO.CCl., C.H., [71°]. (Zinin, A. 119, 177); [61°] (L.). Formed from benzil and PCl., Prisms (from ether). Reduced by zinc and HCl to phenyl benzyl ketone.

PHENYL CHLORO-BENZYL SULPHONE CH.CO.CHCI.O.H. Formed by heating benzylidene obloride with C.H., SO.Na and alcohol at 150° (Otto, J. pr. [2] 40, 517). Needles (from HOAc), sl. sol. hot alcohol.

PHENYL-CHLORO-ETHANE v. CHLOBO-

ETHYL-BENZENE. PHENYL CHLORO-ETHYL OXIDE

**Chloro-thyl derivative of Phenon.

PHENYL CHLORO-ETHYL SULPHONE
C.H., SO., CH., Chl. (56°). Formed by the action of PCl, or HCl on phenyl oxy-ethyl sulphone (Otto, J. pr. [2] 30, 197). Six-sided tablets (from benzene), sl. sol. water.

Reactions.—1. Boiling with alcohol and Ag₂O

converted it into O.H., SO., C.H., OH. — 2. By heating with Q.H., SO., C.H., — B. Sodium-dradgam reduces it, in alcoholic solution, to benzene sulphinic acid.—4. Alcoholic NaOEt forms O.H., SO., C.H., OEt. — 5. Converted by P.H. SO., C.H., OET. — 6. Ammonia column (C.H., SO., C.H.,)2. — 6. Ammonia

CH.SO. CHCI.CH. [52°]. Formed by heating aqueous CH. CCI.CO.Na (1 mol.) with sodium benzene sulphinate (2 mols.) at 100° (Otto, J. pr. [2] 40, 532). Crystals (from alcohol). PHENYL-CHLORO-IMERAMN v. ISATIN. PHENYL CHLORO-METHENYL DI-ETHYL

TRI-SULDHONE CCI(SO2Ph)(SO2Et)2. [130°]. Got by chlorinating CH(SO,Ph)(SO,Et), (Laves,

B. 65, 863). Plates, sl. sol. hot water.
TRI-PHENYL CHLOROMETHENYL TRI-SULPHONE CC(SO,Ph), [260°]. Got by chlorinating CH(SO,Ph), (Laves, B. 25, 350).

PHENYL CHLORO-METHYL KETONE v. Got by

CHLORO-ACETOPHENONE

PHENYL CHLORO-METHYL SULPHONE

C₄H.,SO₂.CH.Cl. 753°]. Formed by boiling an
aqueous solution of C₄H₃SO₂Na (2 mols.) with the theoretical quantity (Otto, J. pr. [2] 40, 527; 32, 21, 656). Formed also from C.H., 80, Na and CH,Cl2

Phenyl di-chloro-methyl sulphone C.H.SO.CHCl. [59°]. Formed by treatment of C.H.SO.CH.CO.H with Cl in diffused days light (Otto, J. pr. [2] 40, 511). Monocl prismatic tables, v. sol. hot alcohol.

PHENYL-CHLORO-NAPHTHYL-AMINE. Monoclinia

Bensoylderivative C₆H,NBz.C₆H₆Cl. [152°]. Formed from NPhBz.C₁₆H, and PCl. (Claus a. Richter, B. 17, 1590). Needles, sol. alcohol. PHENYL-GHLORO - NITRO - PHENYL-HY-

DRAZINE C.H., N2H2.C.H3Cl(NO2) [1:4:6]. [140°].

DRAZINE C₂H., N₂H₂C.,H.,Cl(NO₂) [1:4:6]. [140]. Formed from phenyl-hydrazine and C₄H.,Cl(NO₂). in the cold (Willgerodt, J. pr. [2] 37, 355). Red prisms (from alcohol and ether).

PHENYL TRI. CHLORO OXY PROPYL

KETONE C₂H.,COCH.,CH(OH).CH., [64°] and [77°]. Got from acetophenone, chloral, and HOAc (Koenigs, B. 25, 795). V. sl. sol. water. Converted by H.,SO, into C₆H.,CGCH:CH.CCl, 1103°]. [102°]

PHENYL CHLORO PHENYL HYDRAZINE C₂H₂,N₂H₂,C₃H₄,D₄D₅ Formed by reducing C₄H₂,N₂,C₄H₄Cl with alcoholic ammonium sulphide (Heumann a. Mentha, B. 19, 1688).
PHENYL CHLORO-PHENYL RETONE

CHLORO-BENZOPHENONE

PHENYL-CHLORO-PROPIONIC ACID CHLORO-PHENYL-PROPIONIC ACID

PHENYL &-CHLORO-p-TOLYL RETONE
C.H., CO.C., H., CH., Cl. Benzoylbenzyl chloride. ketone at 110° (Thorner, A. 189, 89). Silky needles (from dilute alcohol). May be sublimed. On further chlorination at 135° it yields phe On ruther chiormation at 135° It yields phenyl dichlorotolyl ketone or benzoyl benzylidene chloride C₂H₄.CO.C₂H₄.CHCl₂ [95°] and, at 155°, phenyl tri-chloro-tolyl ketone or benzoyl-benzo-trichloride C₂H₄.CO.C₂H₄.CCl₄ [111°], which is converted by PCl₄ into C₄H₄.CCl₄.CH₄.CCl₄ [80°] crystallising in thin plates.

PHENYL-CHRYSYL-THIO-URBA

CHANGO NUC. 1 (186°) Formed to the children of the converted to the converted to the children of the childr

C.H.NH.CS.NH.C.,H.1. [186°]. Formed from phenyl-thiocarbimide and chrysylamine and from chrysyl-thiocarbimide and aniline in benz-

ene solution (Abegg, B. 24, 957). Crystals.
PHENYL-GINGHONIC ACID v. PHENYL

PHENYL-CINCHONIDINE FHENYL-CINCHONIDINE C₁₀H₂₁PhN₂O. Formed in two modifications (an oil, sol. ether, and an amorphous powder, insol. ether) by heating cinchonidine with aniline (Claus a. Bätcke, B. 18, 2194). Both give B"H2PtCl, 2aq.

PHENYL-CINNAMIC ACID C₁₈H₁₂O₂ i.e.

C.H. CH:CPh.CO.H. [170°]. Formed by saponifying the nitrile or heating sodium phenylacetate with banzoic aldehyde and Ac.O at 150° (Oglialoro, G. 9, 429). Needles, sol. alcohol and ether, v. sl. sol. cold water. Reduced by sodium-

ether, v. sl. sol. cold water. Reduced by sodium-amalgam to $\alpha \beta$ -di-phenyl-propionic acid.— BAA_24aq: micaceous plates. Methyl ether MeA'. [78°] (Cabella, G. 14, 114). Needles (from dilute alcohol). Nitrile C.H.CH.CH.CN. Phenyl-styryl cyanide. [87°]. (360° cor.). Formed by the action of benzyl cyanide on henzoic aldehyde on benzylidene chloride in presence of NaOEt or solid NaOH (Rossolymo, B. 22, 1235; Meyer, A. 250. 124: Janssen. A. 250. 129: Nebre. A. A. 250, 124; Janssen, J. 250, 129; Neure, A. 250, 155; Frost, A. 250, 157). White plates (from alcohol). Yields CHPhBr.CPhBr.CN [130*] and CHPhCl.CPhCl.CN. [168°].

e-Carboxylic acid. Imide

C.H. CO NH. [174°]. Formed by heating the imide of carboxy-phenyl-acetic acid (vol. i. p. 706) with benzoic aldehyde (Gabriel, \hat{B} . 20, Needles.

References .- NITRO- and OXY- PHENYL-CIN-NAMIC ACID.

PHENYL-CINNAMYL-HYDRAZINE CHPh:CH.CH, NPh.NH, [54°]. Formed from sodium phenyl-hydrazine and cinnamyl bromide (Michaelis, B. 22, 2233). Crystals.

PHENYL-CINNAMYL KÉTONE v. PHENYL STYRYL KETONE.

PHENYL-p-COUMARIC ACID [1:4]

 $C_6H_4(OH)$.CH.CH.CO.H. [219°]. Formed by heating p-oxy-benzoic aldehyde with Λc .O and sodium phenyl-acetate and boiling the resulting acetyl derivative with baryta-water (Oglialoro, (J. 13, 173). --AgA': nearly insol. water. Acetyl derivative. [170°]. Methyl ether MeA'. [170°].

Ethyl ether HeA'. [170]. Methyl deriver Eth'. [152].

Ethyl ether Eth. [152]. Vol.iii.p. 738.

Methyl derivative. [489]. Vol.iii.p. 738.

PHENYL-COUMARIN C₁₅H₁₀O₂. [140].

Formed, together with C₂H₄(OAc).CH:CPh.CO₂H, by heating salicylic aldehyde with sodium phenyl-acetate and Ac₂O for 8 hours at 150° (Oglialoro, G. 9, 428). Prisms, sol. ether.

Mono-sulphonic acid C12H2O2(SO3H) 212q. [263]. White needles (Curatolo, G. 14, 257).

—BaA'₂.—PbA'₂4aq: needles, m. sol. hot water.

Disulphonic acid C₁₃H₂O₂(SO₃H), 6aq. [89°]. Deliquescent crystals.—BaA', 4aq: white prisms.—PbA', 5aq: needles, v. sol. water. PHENYL-CROTONIC ACID C₁₆H₁₆O₂ i.e.

C.H. CH: CMe.CO.H. Phenyl-methacrylic acid. (a)-Methyl-cinnamic acid. [82°]. Formed by heating benzoig aldehyde with propionic anhydride and sodium propionate (Perkin, C. J. 31, 391; 32, 661). Formed also by heating benzoic aldehyde with Ac.O and sodium methyl-malonate; and by heating benzois aldehyde with sodium propionate and HOAc or Ac,O (Stuart, C. J. 48, 404; Slocum, 4 227,57). Obtained also by oxidation of the corresponding aldehyde (Miller a. Kin-kein, B. 19, 526). It is also a product of the action of Na on benzyl propionate (Conrad a. Hodgkinson, A. 193, 814).

Transparent plates (from alcohol), sl. sol, hot water. When prepared by Perkin's method it ap pears to be accompanied by an isomeride [740] crystallising in needles, which is converted into the crystallising in needles, when is converted into the acid [82°] by frequent recrystallisation (Raikoff, B. 20, 3396). Yields methrohol (q, v.) when, heated with dilute H₂SO₄. Bromine forms CHPBR₂CMeBr.CO₂H[137°] (Körner, B. 21, 276).

Balt's—Bal', aq: very minute, plates.—
Bal', 4aq: small white crystals, got by slow cooling.—AgA'. S. 374. Needles.

Methylether MeA'. [30°]. (254°).

Amige 128°] [Edeleano, B. 20, 619).

Phenyl-isocretonic acid.

C₄H₅.CH:CH.CH₂.CQ.H. [86°] (J.); [88°] (B. s. D.). (302°). Formed by heating ben2oic aldehyde with succinic anhydride and sodium succinate (Perkin), the yield being 2 p.c. (Jayne, A. 216, 100). • Formed also by heating phenyltrimethylene tricarboxylic acid C.H.Ph(CO.H). in a current of Co at 190° (Buchner a. Dessauer, B. 25, 1155). Prepared by heating benzoic aldehyde with sodium succinate and Ac.O at 125°, and separated from phenyl-paraconic soid by solution in CS₂. Long thin needles (from water) or prisms (from CS₂). When heated with H₂SO₄ (4 pts.) and water (4 pts.) it changes to the isomeric phenyl butyrolactone and an acid [179°] (Erdmann, A. 227, 257). Yields γ -phenyl-nbutyrio acid [49°] on reduction. Boiling NaOHAq converts it into the isomeric C.H.,CH.,CH.;CH.CO.,H [55°]. Split up by long boiling into water and (a)-naphthol. Alkaline KMnO, at 0° forms di-oxy-phenyl-butyric lactone (Fittig a. Obermüller, A. 268, 44).—BaA', 3aq.—

CaA', 3aq. — AgA': bulky pp.
a-Phenyl-crotonic acid CH, CH: CPh.CO, H. Methylatropic acid. [185°]. Formed by heating sodium phenyl-acetate with paraldehyde and Ac₂O (Oglialoro, G. 15, 514). Minute prisms (from water), sol. alcohol and ether.—AgA': m. sol. hot water.

Phenyl-crotonic acid CaH, CH:C(CH,Ph).CO,H. [158°]. Formed from sodium phenyl-propionate, benzoic aldehyde, and Ac.O at 160° (Oglialoro, G. 20, 162). Needles (from alcohol).

Reference. -- OXY-PHENYL-GROTONIC ACID. PHENYL-CROTONIC ALDEHYDE v. PHENYL-METHACRYLIC ALDEHYDE

PHENYL-CUMAZONIC ACID

 $C_{17}H_{15}NO_{2}$ i.e. $C_{6}H_{2}(CO_{2}H) < \frac{CMe_{2}O_{2}}{N}$ [220°]. Formed by heating (3,4,1)-amido-oxypropyl-benzoic acid with BzCl at 100°-120° (Wid-

pyl-benzoic acid with B2Cl at 100°-120° (Wid-mann, B. 16, 2585). White crystals. Sol. alcohol, insol. water.—HA'H,SO, 2aq: thin plates. PHENYL-CUMINYL-AMINE C_{i.H.i.N} i.e. C_{s.H.i.N}II.CH_{.C.i.H.}Pr. [41°]. Formed by re-ducing C_{s.H.i.N}I.CH.C.H.Pr (Uebel, A. 245, 289).

PHENYL-CUMINYL-THIO-UREA
PHENYL-CUMINYL-THIO-UREA
PHENYL-CUMINYL-THIO-UREA
PHENYL-CUMINYL-THIO-UREA
PHENYL-CUMINYL-THIO-UREA [100°-106°]. C.H.Pr.CH2.NH.CS.NHPh. Formed from cuminylamine and phenyl-thio-

romed from cummytamine and phenyr-more carbimide (Goldschmidt a. Gessner, B. 20, 2416)
PHENYL-CUMINYL-UREA C₁,H₂N₁O i.e.
C₁H₁NH.CO.NHC₁eH₁₁. [144°]. Formed from cuminyl cyanate and aniline (Baab, B. 8, 1151)

NPh:C(NH.C.H.(C.H.)[1:4]). Formed from dicumyl-thio-ures and aniline (Francksen, B. 17, 1226). · Resin. ·

PHENT. 4-CUMYL KETONE C., H. O. i.e.

O.H., CO.C.H.Me, [1:2:4:5]. (329°). From
BzCl, 4-cumene, CS, and ACl, (Elbs, J. pr. [2]
35, 491; C. Claus, B. 19, 2891); the yield is
65 p.c. of the calculated.

Reactions .- 1. Boiling produces small quantities of needles [180°], probably (B. 2,8)- di methyl-anthraquinone.—2. Conc. or furning H.SO, st 100° forms benzoic acid and d-cumene sulphonic acid C.H.Me.(SO.H.) [1:2:4:5].—8. Funning HNO, mixed with H.SO, gives two isomeric trinitro-derivatives; one [185°] is v. al. sol. alcohol, the other [155°] is m. sol. v. at soil atcolor, the other [100] is in soil.

alcohol.—4. Dilute nitric acid forms bensayltrimellitic acid. C.H..CO.C.H..(CQ.H), and
C.H..CO.C.H..Mc(CO.H).
Phenyl cumyl ketone C.H..CO.C.,H.Pr.
(348°) at 788 mm. Formed from curringly

chloride, benzene, and AlCl, (Smith). • Yields two oxims [106°] and [132°], the latter of which forms an acetyl derivative [90°].

Phenylen-cumyl ketone. C.H., CO.C.H.Pr. (845° at 716 mm.). Formed from n-cumene, BsCl, and AlCl, (Smith, B. 24, 4033). Yields two oxims [180°] and [104°], which yield acetyl derivatives, melting at 116 and 60°.

PHENYL-4-CUMYL-METHANE CAR3OXY.

LIO ACID [1:2:4] C.H.M., C.H., C.H., CO.H. [1:2] [1869]. Got by reducing C.H., Mc.CO.C. H., CO.H with Zn and NH, Aq (Gresly, A. 234, 238).
DI-PHENYL-W-CUMYL-METAPYRAZOLE

TETRAHYDRIDE C. H.N. i.e.

C,H,,,CH<NPh>C,H,. [125°]. Formed from

p-cuminio aldehyde and di-phenyl-ethylene-di-amine at 100° (Moos, B. 20, 738). Silky needles. PHENYL-UCUMYL-UREA C₁₀H₁₁N₁O i.e. NHPh.CO.NHC,H₂Me₁ [211°]. Formed from w-cumidine and phenyl oyanate (Goldschmidt a. Bardach, B. 25, 1361). White needles. PHENYL-UYANAMIDE v. vol. ii. p. 316. Di-phenyl-oyanamide C₄H₁₀N₂ t.e. C(NPh)₂. Carbodiphenyl-bride. Mol. w. 194. (631° cor.).

Formed by warming a solution of s-di-phenylrormed by warming a solution of the Arrival Rev. 10, 1803; 9, 810). Syrup, drying up to a vitreous mass. Changes spontaneously into an opaque polymeride [170°] resembling porcelain.

Reactions.—1. Boiling dilute alcohol con-

verts it into s-di-phenyl-urea.—2. Aniline yields (a)-tri-phenyl-guanidine.—3. H₂S passed into its solution in benzene forms CS(NHPh)₂.—4. s-Diphenyl-thio-urea at 150° forms phenyl-thiocarb-imide and (a)-tri-phenyl-guanidine. — 5. Di-phenyl-urea at 150° acts in like manner, forming phenyl-wree at 150° acts in like manner, forming phenyl cyanate and tri-phenyl-guanidine.—6. Phenyl-hydrasine at 120° forms the compound C.H.N.:C(NHPh), [204°] which gives the salts B'HCl, B'zH.PcOl., and B'H.SO,, and is converted, by heating with phenyl-hydrazine at 185°, into C.zH.,N. [200°], which gives the salts B'zH.Cl, and B'zH.PCl.. The compound PhN.:C(NHPh), is converted by heating with phenyl-thiocarbimide at 190° into C.zH.,N.S [176°], and by heating with di-p-tolyl-dyanamide

and from phenyl cyanate and cuminylamine into C.H.N. [128°] which gives the salts (Goldschmidt, B. 20, 2415). Small needles.

BHENYL-DI-OPMYL-GUANIDINE

HCV passed into its solution in benzelle forms (C.H.), N. crystalliging from alcohol in prisms [1379]. A little of its solution in H.SO, mixed with water is coloured deep blue by NaOH (Laubenheimer, B. 13, 2155).—8. Tolyleneodiamine at 135° forms C.H., N. [1619] which yields B',H,Cl, [174°] (Dahm a Gasiorowski, B. 19, 3057).

Salt .- B'HCl. Needles (from benzene).

Tri-phenyl-di-eyan-di-amide C₂₀H₁₆N₄.
Formed from NHPh.CS.NH.C(NPh).NHPh, alcohol, and HgO, and also by heating di-phenylconol, and ngo, and also by nearing at pressing guanidine at 175° (Bathke a. Oppenheim, B. 23, 1673). Yellow needles (containing EtOH) (from alcohol).—B'HCl. Needles, insol. water.

—B',H,PtCl, 2aq.—B',H,SO,2aq.

—B',H,SO,2aq.

Reference.—OXY-PHENYL-CYANAMIBE.

PHENYL CYANATE v. vol. ii. p. 315.

PHENYL-CYANIC ACID v. CYANIC ACID.
PHENYL CYANIDE v. BENZONITRILE and PHENYL-CARBAMINE.

Di-phenyl dicyanide C, H, N, i.e.

PhC≪N>CPh? [152°]. Formed from benzamidine and benzoic aldohyde (Pinner, B. 22, 1610; 23, 2925). Prisms. Changes at 200°-270° into cyaphenine.

PHENYL-CYANUEIC ACID v. Cyanuric

acid in the article on Cyanic acid.

PHENYL-p-CYMYL-CARBINOL C₀H₃,CH₂(OH),C₂H₃(C₃H₂) [1:2:5]. (327° uncor.). Formed by reduction of phenyl p-cymyl ketone (Claus a. Elbs, B. 18, 1798; J. pr. [2]

35, 497). Thick colourless oil. PHENYL .-CYMYL ECTONE C.,H,,O i.e. C,H,,CO.C.,H,MePr[1:2:5]. (224° at 40 mm.); (340°) at 760 mm.

Formation.—1. From cymene by heating with benzoic acid and P₂O₃ (Kollarits a. Merz, B. 6, 546, -2. From cyanene, BzCl, and zino (Grucarevic a. Merz, B. 6, 546, 1246). -3. From cymene, BzCl, CS_x and AlCl, (Elbs, J. pr. [2] 25, 4041 35, 494].

35, 494].

Properties.—Yellowish oil, v. sol. alcohol and ether, m. sol. HOAc. Very slightly volatile with steam.

Reactions .- 1. Bromine and iron powder at 140° give benzoic acid and bromo-cymene, C_sH₃BrMePr [1:2:5] [232°]. — 2. Conc. H SO₄ and KNO, give an amorphous di-nitro-deriva-tive.-4. Dilute PNO, gives benzoyl-terephthalic acid .- 5. Concentrated H2SO, at 100° gives benzoic acid and cymene sulphonic acid.

C.H.,MePr(SO.H) [1:4:2]. PHENYL-CYSTEINE C.H., NSO. i.e. PHENYL-USELEMB U.H. INCO. 1-6.
CH., C(SPh)(NH.). CO.H. Formed by boiling phenyl-mercapturic acid with dilute H.SO. (Baumann a. Preusse, H. 5, 337). Plates (from NH.AQ) or six-sided tables (from water), v. sol. acids and alkalis, sl. sol. cold water. Yields phenyl mercaptan on boiling with NaOHAq.

Reference. BROMO-PHENYL-CYSTRING. PHENYL-DECOIC ACID. Nitrile C.H.,OH(C.H.,),ON. (328°). Formed from benzyl cyanide, octyl iodida, and NaOH (Rossolymo, B. 32, 1337). Yellow oil.

PHENYL-DURYL-GARBINOL

[6:4:8:2:1] C₄HMe, CH(OH).O₄H₄. (above 860°)e Formed by seduction of phenyl iso-duryl ketone

Essuer a. Gossin, Bl. [2] 42, 172). Liquid. fields an acetyl derivative boiling above 160° inda bensoyl derivative [75°].

DI PHENYL DURYLENE DIRETONE
J.H.O. i.e. (C.H.CO),C.Me. [270]. (above
180°). Formed from derene, BzCl, and AlCl, Friedel a. Crafts, A. Ch. [6] 1, 512). Prisms.

PHENYL DURYL KETONE C,, H,O i.e. leH.CO.C.HMe. [119°]. (343°) at 725 mm. for from durene, BzCl, and AlCl, (Friedel a. rafts, A. Ch. [6] 1,511). Acioular prisms, v. sol. rarm alcohol. Reduced by HI and P to C., H., 50.59 (310° at 716 mm.). Brooms C., H., Br., O 225°] and other products.

Phenyl isoduryl ketone. [63°]. (300°). ormed by the action of BzCl and AlCl, on the isodurene derived from toluene (Essner a. Gossin, Bl. [29, 42, 170). Suggessive treatment with HCy and alcoholic potash gives the said C.HMe..CPh(OH).CO.H, sol. water and alcohol.

PHENYLENE. The Padicle C.H. PHENYLENE-ACETAMIDINE

C_eH₄<NH>C.CH₂. [170°] (H.); [175°] (L.). Formed by boiling phenylene-o-diamine with HOAc, or by reducing C₄H₄(NO₂)(NHAc) with tin and HCl (Ladenburg, B. 8, 677; Hübner, A. 209, 353). Needles.—B'HCl.—B'₂H₂PtCl₈ aq.— B'HNO₃.—B'H₂SO₄.

Phenylene - di - acetamidine C10H14N4 [1:4] C_oH₁(CH₂C(NH),NH₂). [182°]. Formed by the action of alcoholic NH₃, followed by NaOHAq, upon the hydrochloride of phenylenedi-acetimido-ether (Glock, B. 21, 2660). Plates.

o-PHENYLENE-DI-ACETIC ACID $C_{10}H_{10}O_4$ e.e. [1:2] $C_aH_4(CH_2\cdot CO_2H)_2$. Mol. w. 194. [150°]. Formed by saponification of its nitrile by boiling with dilute H.SO, (Baeyer a. Pape, B. 17, 44%. Slender needles, v. sol. alcohol, m.

sol. cold water.—Ag.A". insoluble pp.

Nitrile C.H.(CH.CH.). [60°]. Form
by the action of KCy on di-ω-bromo-o-xylene.

m-Phenylene-di-acetic acid C.H. (CH2.CO2H)2.

m-Phenylene-di-acetic acid C_sH₁(CH₂·CO₂H)₂.

[170³]. Formed by-boiling its nitrile with alcoholic potash (Kipping, C. J. 53, 42; B. 21, 42).

Needles, v. sol. water.—Ag₅A'': white pp.

Nitrile C₂H₁(CH₂CN)₂.

[29³]. (308° at 300 mm.). From [1:3] G₂H₁(CH₂Br)₂ and gCy.

p-Phenylene-di-acetic acid C₃H₁(CH₂CO₂H)₂.

[241³]. Got from its nitrile (Biedermann, B. 5, 703; Klippert, B. 9, 1766; Kipping, C. J. 53, 44). Needles, m. sol. water.—CaA''2aq.—

[taA''Rag.—RaA''2iag: needles, v. sol. water.

44). Needles, m. sol. water.—CaA" 2aq.—CaA" 8aq.—BaA" 2½ aq: needles, v. sol. water.—ZnA".—CaA".—Ag.A": white amorphous pp. Ethers.—Me.A". [57°].—Et.A". [58°]. Chloride. Oil (Klippert).

Amide. [above 290°]. Plates and needles. Nitrile C.H.(CH.CN)... [96°]. Formed by the action of KCy on C.H.(CH.Br), or C.H.(CH.Cl)... Three-sided prisms (from other). Alcoholic ammonium sulbhide at 100° converts Alcoholic ammonium sulphide at 100° converts it into C₆H₄(CH₂CS.NH₂)₂ [206°] which crystallises from HCAc.

Di-phenylene-acetic acid C.H. CH.CO.H. [222°]. Formed by heating C_{1.}H₁:C(OH).CO_.H with HI and P at 140° (Friedländer, B. 10, 538). Small crystals (from alcohol). Decomposed by heating with soda-lime into CO₅ and fluorens.— AgAb: unstable pp.

Ethul ether Etk'. [165°]. Reference .-- OXY-DIPHENTLENE-ACETIC ACID. Reference.—UXY-DEPHENYLENE ACETIC ACID.
p-PHENYLENE DI-ACETTRIDO-ETHER
C.H.(CH.-C(NH)-OEt). The hadrochloride
B"2HCl [above 240°] formed by the action of
alcohol and HCl on C.H.(CH.-CN), crystallises
in needles (Glock, B. 21, 2660). It is insol, ether.

o-PHENYLENE-DI-ACRYLIC ACID C.H.(CH.CO.H)₂. [above 300°]. Formed by boiling C.H.(CH.;CCI(CO.Et)₂)₂ with also holic potash (Perkin, C. J. 53, 14; B. 19, 435). Sl. sol. water, v. sl. sol. alcohol.—Ag.A": pp.

p-Phenylene di-acrylic acid p-Phenylene di-acrylic acid C.H.(CH:CH.CO.H), [310°]. Obtained by saponitying the mono-ethylether HEtA* [200°] which is got by heating p-aldehydo-cinnamic ether with NaGAc and Ao.O (Low, A. 231, 377). Got also by boiling C,H.(CH.,CBr(CQ.Et)), with alcoholic potash (Kipping, C. J. 53, 41). Yields a tetrabromide crystallising in needles.—Ag.A.".

PHENYLENE - DI - ALLYL - DI - THIO - DI -UREA C.H.(NH.CS.NHC,H.)2. The o- [159°], m- [105°], and p- 200°] compounds are formed by heating the corresponding phenylene-diamines with algohol and allyl-thiocarbimide (oil of mustard) at 100° (Lellmann a. Würthner, A. 228, 201). The o- and p- compounds decompose when heated. They are all sol. HOAc.

o-PHENYLENE - DI - AMIDO - DI - ACETIC ACID [1:2] C.H. (NH.CH., CO., H). The ether Et. A'' [135°] is got from o-phenylene diamine and ClCO Et (Zimmermann a. Knyrim, B. 16, 515).

m-Phenylene-di-amido-di-acetic acid m-Phenylene-di-amido-ai-acetic acia [1:3] C_sH_s(NH.CH_sCO_sH)_s. The ethyl ether Et.A" [78°] is got by heating m-phenylene-diamine with OH_sCl.CO_sEt (Zimmermann B. 15, 518; 16, 514). It is converted by conc. HClAq into crystalline HA"H_sCl_s v. sol. water. p-Phenylene-di-amido-di-acetic acid. The

ethyl ether Et.A" [83°] and the hydrochloride. H2A"H2Cl2 are formed in like manner from p-phonylene-diamine.

o-PHENYLEME-DIAMINE [1:2] C₆H₄(NH₂)₂ Mol. w. 108. [104°]. (252°). Prepared by reducing o-nitro-aniline with tin and HCl (Zincke Sintenis, B. 6, 123; Vignon, Bl. [3] 2, 675; Sandmeyer, B. 19, 2654). Formed also by heating the corresponding di-amido-benzoic acids with baryta (Griess, J. pp. [2] 8, 148; Salkowski, A. 173, 58) and by the action of tin and HCl on bromo-o-nitro-aniline (Wurster, A. 171, 63; Hübner, A. 209, 360) and on o-di-nitro benzene (Zincke, B. 7, 1874). Plates (from water) or tables (from chloroform), v. e.

sol. hot water, sloohol, and ether.

Reactions.—1. FoCl, added to a solution of the hydrochloride forms di-amido-phenazine hydrohydrochloride forms di-amido-phenazine hydrochloride, which crystallises in ruby-red needles C₁.H₁.N₄.HCl (Fischer, B. 22, 355).—2. Pyrocatechin at 200° forms phenazine C₂.H₄.N₃.C₄.H₄. S. (B)-Naphthoquinone forms naphthophenazine C₁.H₄.N₄.C₄.H₄.—4. Cyanogen gas forms C.H₄.N₄ a yellow crystalline powder [c. 280°], sl. sol. water, forming B'.H.PtCl, 3aq and B'.H.PtCl, aq. By heating with HCl it is converted into C.H.N₄.O [280°] and di-oxy-quinoxaline (Bladin, Bl. [2]42, 104; B. 18, 672).—5. The sulphocyanide is converted by heat into a mixture of phenylengverted by heat into a mixture of phenylenethio-urea and thio-urea (Lellmann, A. 221, 8).-6. KNO, added to a very dilute solution of the sulphate forms 'amidoszophenylene' C.H.N.

meedles [98-6] (Ladenburg, B. 9, 219).—7. ICy forms C_{1,H},N_c, which yields the salts B"H_{cl}, b" ACI 2\(\) aq, B" 2HNO, 2\(\) aq, and B"H_c, N_c, Q_c thin y intro us següin to C_{1,H}, N_c, Q_c thin by prictors again to C_{1,H}, N_c, Q_c thin by prictors again to C_{1,H}, N_c, Q_c thin be converted by benzoic aldehyde into dibenzylidene amplene diamine (C_{1,H}, (N.C) Hh)_c, 134 C₁; yieldigh B'_c H_cPtCl_c. B'HNO_c B'H_cSO_c. B''H_cNO_c B'H_cSO_c. B''H_cSO_c. B''

benzenyl-pnenylene-diamine (q. v.).

Dibenzoyl derivative C.H.(NHBz).

[c. 300°]. Thin prisms (from HOAc) (Bistrzycki).

Di-p-toluyl derivative
C.H.(NH.CO.C.H.Me). [228°]. Got, logother with tolenyl-benzamidine C.H.(N.H.CO.H.Me [268°], by the action of p-toluyl chloride on o-phenylene-diamine dissolved in benzene (Hübner, A. 210, 828). Colourless needles, sl. sol. alcohol.

m-Phenylene - diamine C_aH₁(NH₂)₂. [63°]. (277° i.V.). Prepared by reduction of m-dinitro-benzene or m-nitro-aniline (Hofmann, Pr. 11, 518; 12, 639; Zincke, B. 5, 792). Formed also by heating s-di-amido-benzole acid with baryta (Wurster, B. 7, 214; Hübner, A. 222, 86), and by the action of tin and HCl on (4,2,1)-di-nitro-benzole acid (Wurster, B. 7, 149) and on (1,2,4)-bromo-di-nitro-benzene (Z.). Got also by heating resorein (1 pt.) with ammoniacal CaCl, (4 pts. containing 35 p.c. NH₃) for eight hours at 275° (Seyewitz, C. R. 109, 814). Crystalline, m. sol. water, v. sol. alcohol and ether. Its solutions are alkaline in reaction. KNO2 added to a solution of a salt of m-phenylene-diamine forms a brown pp. containing C₄H₃(NH₂)₂N₂C₆H₁NH₂. A solution in dilute H₂SO₄ is coloured yellow by a trace of nitrous acid. Aldehyde added to an alcoholic solution of m-phenylene-diamine hydrochloride forms an orange-red colour, with a green fluorescence. orange-red colour, with a green hoursescence. From this liquid NH_{*}Aq ppts. di-methyl-phenanthroline tetrahydride $O_{i_1}H_{i_2}N_{i_3}$ (Girard a. Roques, C. R. 107, 1158; Schiff, A. 253, 328). Benzoic aldehyde in alcohol forms with the hydrochloration of the colour of the colou The hydroide the base CHPh(C₆H₄(NH₂)₂)₂. chloride of m-phenylene-diamine gives a crimson colour when boiled with oxygenated water (Deniges); in presence of ammonia the liquid becomes blue, but is turned red by NaOHAq. Hydrogen peroxide gives a bluish-green tina (Cazeneuve, Bl. [3] 5, 855) PbO₂ and dilute HOAc give a brown colour (Lauth, C. R. 111, 975). Alkaline NaOBr gives a maroon-red pp. (Deniges, 6. R. 107, 662). CS, in alcohol at 35° forms

yellow monochnic prisms of C.H. NH CS and several other bodies (Gucci, G. 17, 523, 2657). The sulphocyanide is converted by heat into added to a solution of the hydrochloride forms $C_cH_c(NH_cCS,NH_c)_c$ (Lellmann, A. 221, 8).

The sulphocyanide is converted by heat into added to a solution of the hydrochloride forms $C_cH_c(NH_cCI)N_cCI$, and in presence of a large excess of HCI it forms $C_cH_c(N_cCI)_p$.—6. Mixed

C,H,(NHAc)2.4

m-Amido-bensoyl derivat\$vs $C_sH_4(NH_2)(NH.Co.C_sH_NH_2)$. [129°]. Needles (from dilute alcohol) (Hugh, B. 7, 1268).

o-Oxy-benzoy) derivative C_sH₁(NH_s).NH.CO.O_sH_sOH. [143°]. Orystals (Bell, C. J. 28, 1201).

• p-Phenylene-diamine C.H.(NH.).

Formation .- 1. By reduction of Formation.—1. By reduction of p-nitro-aniline and of p-di-nitro-benzene (Hofmann, Pr. 11, 518; 12, 639; Zincke, B. 7, 871).—2. By reduction of C_uH₁, N₁, C_uH₁, NH₁ (Martius a. Griess, Z. 1866, 136).—3. By distilling (5,2,1)-di-amido-benzoia acid (Griess, B. 5, 201).—4. In the pre-paration of induline by heating C_uH₁, N₁, C_uH₁, NH₁ with aniline hydrochloride (Witt; Fischer a. Happ. B. 23, 2920. Hepp, B. 23, 839).
Prenaration.—From acelanilide by nitration

Preparation.—From acetanil and reduction with tin and HCl.

and reduction with tin and HCl.

Properties.—Plates (by sulfilmation) or
monoclinic crystals (from waker) changing in
the solution to trimetric plates. Mosol. water,
v. sol. alcohol and ether. Forms a hydrate
C,H,N,2 aq [80°]. With PbO₂ and aqueous HO₂
it gives a bright bluish-green colour (Lauth,
C.R. 111, 975). p-Phenylong-diamine is very
poisonous (Vignon, C. R. 107, 533). A mery
race of a mixture of m and p- phenylene-diamine gives on warming with HOAo and K,Cr.,
hlue colour changing on boiling to red [W].

amine gives on warming with HOAc and K.Cr.O. a blue colour, changing on boiling to red (Witt, O. J. 35, 356; Meldola, C. J. 51, 105).

Reactions.—1. Ornitised to quinone by H.SO., and MnO.. Quinone is also formed together with NH, by oxidation of the sulphate with K.Cr.O., (Meldola a. Evans, C. J. Proc. 5, 115).—2. When exposed to air, O. H.O., or K.FeCy, p. phenylene-diamine and its salts are oxidised to C.H.N., a feeble red base with green lustre [2307] yielding C.H.AcN, [2947] (Bandrowski, M. 10, 126).—3. Chlorine passed into a solution in HOAc forms tetra-chroro-quinone,—4. FeCl. added to a solution of the hydro-4. FeCl, added to a solution of the hydrochloride saturated with H.S ppts. Lauth's violet, which is v. sol. pure water, but ppd by salts (Lauth, C. R. 82, 1441).—5. Potassium nitrite

with aniline (2 mols.) and oxidised by K,Cr,O, it yields pheno-safranine .- 7. The sulphocyanide is sometised by heat into $C_sH_s(NH.CS.NH_s)_s$ (Leilmann, A. 221, 8).—8. Bleaching-powder solution added to a solution in HClAq ppts. yellowish-white quinone di-chloro-di-imide which detonates at 124° (Krauso, B. 12, 47). -9. Aceto-acetic ether at 170 forms C, H, N, O, [176°] which is probably C₂H₄(NH.CO.CH₂.CO.CH₃)₂ (Knorr, B. 17, 545; 19, 3303).

Salts.—B"H₂Cl₂. Triclinic tables, v₂ sol. water, almost insol. HClAq.—B"H₂PtCl₂.— B'H.Sn.cl. (Hübner, A. 203 366).—B"H.Br., B'H₂S₂O₃ (Bernthsen, A. 251, 62).—B''H₂S₂O₃.

Micaceous plates, sl. sol. water (Vignon, Bl. [2] 50, 152).—B''H₂C₂O₄. S. 15 at 15°.

Di-formyl derivative C.H.(NH.CHO)...
[204]. Amgrphous mass (Wundt, B. 11, 828).
Mono-acceyl derivative

MONO-actery aervoutives.

C.H.(NH.)(NHAC). [161°]. Formed by reduction of C.H.(NO₂).NHAc with iron and acetic acid (Nietzki, B. 17, 343). Needles, sl. sol. cold water.—B'_2H_PtCl₂.

Di-actery l derivative C₂H₁(NHAc).

[above 295°]. Formed by boiling the base with HOAc (Biedermann a. Ledoux, B. 7, €531). Small octahedra, sol. HOAc.

Behzoyl derivative C₀H₄(NH₂) (NHBz). [128°]. Formed by reducing benzoyl-p-nitro-aniline (Hübner, A. 208, 295). Plates, sl. Sol. water.—B'HCl.—B'₂H₂SO₄. Needles.

Di-benzoyl derivative C₄H₄(NHBz)₂.

[above 300°]. Formed from the base, BzCl, and NaOHAq (Hinsberg, A. 254, 254). Plates. Yields a nitro- product [251°].

o-Oxy-benzoyl derivative

C,H,(NH.)(NH.CO.C,H,OH). [158°]. Glittering

needles (Bell).

Hexahydride C.H.10(NH2)2. Di-amido-hexamethylene. Formed by reducing the di-Di-amidooxim of quinone tetrahydride in alcohol with Na (Baeyer a. Noyes, B. 22, 2172). Liquid, with faint atmoniacal odour, forming crystalline salts and an acetyl derivative melting above 310°

References.—BROMO-, BROMO-NITHO-, CHLORO-, NITRO-, and OXY- PHENYLENE-DIAMINE.

PHENYLENE-DIAMINE SULPHONIC ACID v. DI-AMIDO-BENZENE SULPHONIC ACID.

PHENYLENE-DI-AMYL-DIAMINE

[1:4] C_eH₄(NH.C₅H₁₁)₂. [49°]. Colourless crystals (Baeyer a. Noyes, B. 22, 2173).

DIPHENYLENE-AZONE C_0H_1 , N. [156°]. Formed, together with C12HN2O2 [240°] and $C_{12}H_1N_2O$ [152°] by boiling di-o-nitro-diphenyl with alcohol and zinc-dust (Täuber, B. 24, 3081, 3883). Greenish-yellow needles by sublimation, not volatile with steam. Almost ensol. water, v. sol. sleohol, m. sol. ether, v. e. sol. HOAc. Reduced by tin and HCl to $C_{12}H_{10}N$, HCl, which crystallises in white needles, rapidly reoxidised by ar to diphenylene-azone.

Salts.—B'HCl. Flat bronzed prisms.—
B'HAuCl₄.—B'₂H₄PtCl₅: yellow needles.—
B'H₂CrO₄.—B'C₆H₁N₄O₇. [194°]. Brown needles.

PHENYLENE-BENZALDEHYDINE v. vol. i.

p. 109.

PHENYEENE-BENZAMIDINE v. BENZENYL-PTENTLENE-DIAMINE. Vol. IV.

PHENYLENE-DI-BENZIDENE-DIAMINE v. DI-BENZYLIDENE-PHENYLENE-DIAMINE

PHENYLENE-BENZYL-m-DIAMINE

CaH. (NH2).NHC, H,. Formed by reducing benzyl. m-nitro-aniline (Meldola a. Coste, C. J. 55, 597). Oil. -B"2HCl: hexagonal tablets. FeCl, colours its solution red and gives a white pp. on heating.

Di-bensoyl derivative C.H. (NHBz).NBz.C.H., [178°]. Sol. Tohol. Phenylene-bensyl-p-diamine. [80°]. Got by reducing benzyl-p-nitro-aniline (Meldola a. Coste, C. J. 55, 590) or p-nitroso-benzyl-aniline Costef C. J. 55, 590) or p-nitroso-benzyl-aniline (Boeddinghaus, A. 263, 302). Wax-like mass of crystals, turning red in air. When mixed with the m-isomeride it yields di-benzyl-amido-indamine on oxidation.—B'2HCl. White plates, v. sol. water. FeCl. colours its aqueous solution green, changing to red. After saturation with H.S it gives a blue pp. with FeCl.—Diagraphy desiration. [1179] Primes

Pi-acetyl derivative. [117°]. Prisms. Di-beneoyl derivative. [124°]. Needles. Phenylene-di-benzyl-diamine v. vol. i. p.

Phenylene-tetra-benzyl-m-diamine

C.H.(N/C.H.),2, [81°]. Formed by heating phonylene-m-diamine with NaOHAq and benzyl chloride. Amorphous powder, sol. IIOAc.

Phenylene-tetra-benzyl p-diamine. [149%] White crystalline powder. HOAc and CrO, form a blue-violet colouring matter.

PHENYLENE - BENZYLIDENE - DI -METHYL-DIAMINE C₁₆H₁₆N₂ i.e. C₆H₄,CH:N.C₆H₄,NMe_{...} [93³] (Calm, B. 17, 2940); [101°] (Köhler, A. 241, 361). Formed from phenylene-di-methyl-p-diamine and benzoic

aldehyde. -B"2HCl.

PHENYLENE - BENZYL - DI - METHYL -DIAMINE C.H.CH.NH.C.H.NMe. [48]. Formed by reducing the preceding body in alcohol with sodium-amalgam (Köhler, A. 241, Plates. Yields a nitrosamine [128'].

PHENYLENE-BLUE or Lauth's violet v. Amido-imido-di-phenyl-sulphide.

PHENYLENE - BROMO - ACETYLENE -KETONE v. BROMO-OXY-INDONAPHTHENE.

CH, CH.CH, DI-PHENYLENE-BUTANE Diphensuccindene. [100°]. Formed by heating (β)-di-phenyl-succinic anhydride with H1 and P and 180° (Roser, A. 247, 156). White needles.

PHENYLENE-ISOBUTYL-p-DIAMINE C.H.,NH.C.H.,NH. [39°]. Formed by reduction of p-nitroso-isobutyl-aniline (Wacker, A. 243, 299). Plates (from benzone-ligroin).

PHENYLENE - BUTYLIDENE - o - DIAMINE $C_{_{0}}H_{_{1}} < \stackrel{NH}{\sim} CHPr.$

[233°]. Formed from phenylene-o-diamino and isobutyric aldehyde (Lassar-Cohn, B. 22, 2724). Needles (by sub-limation). – B'HCl. [184°]. -B'₂H,PtCl_s.

The isomeric compound from phenylene-mdiamine melts at 216°, while that from phenylene-p-diamine is oily, and yields B',H,PtCl

DI - PHENYLENE - ISOBUTYL - QUINOX -ALINE C₆H₄,C:N>C₆H₂,CH₂Pr. [\$47°]. Formed from phenanthraquinone in HOAc and isobutylphenylene-diamine in alcohol (Gelzer, B. 20, 3256). Yellowish needles.—B'HCl: needles.

o-PHENYLENE-DICARBAMIC ETHER C.H.(NH.CO,Et)2. [88°]. Formed by heating

o-phenylene-diamine with OlCO, Et (Snape, C. J. 49, 259). Needles (from alcohol).

m-Phenylene-dicarbamic ether. [145°]. p-Phenylene dicarbamic ether. [193°]. Got by heating p-phenylene dicyanate with alcohol (Gattermann a. Wrampelmeyer, B. 18, 2605). Di-phenylene-dicarbamic acid. Eth

ether CO_Et.NH.Q.H., C.H., NH.CO_Et. [230⁵]. Formed from benzidine and ClCO_Et or by boiling diphenylene dicyanate with alcohol (Snape,

C. J. 49, 256; Schiff a. Vanni, A. 258, 369). Di-phenyl ether. [c. 240°]. Matte by heating diphonylene dicyanate with phenol at

140° (Snape). Tables, sl. sol. alcohol.
DI-BHENYLENE CARBINOL C. II. 00 i.e. С.Н.>СН.ОН. Fluorene® alcohol. Formed by reducing diphenylene ketone with sodium-amalgam (Barbier, A. Ch. [5] 7, 504). Hexagonal plates (from benzene). Oxidised by CrO, to diphenylene ketone. And at 190° forms an acetyl derivative [75°]. When heated

rorms an acetyl derivative [75]. When heated above its melting-point, diplemylene carbinol yields C₂₂H₁₈O [290°], a nearly colourless resin.

o-PHENYLENE CARBONATE CALLOGO.

[118°]. (225°-230°). Formed from sodium pyrocatechin and ClCO₂Et (Wallach, A. 226, 84). Four-sided prisms (from alcohol-benzene).

 $C_6H_4 < 0 > CO.$ m-Phonylene carbonate Formed by heating resorcin with cyanuric acid and ZnCl₂, and also by the action of COCl₂ on resorcin (Birnbaum, B. 14, 1753). Amorphous

solid, sol. HOAc. m:-PHENYLENE DICARBONIC ETHER C₂H₁(O.CO₂Et)₂. (298°-302°). Formed from sodium resorcin and ClCO₂Et in ether (Wallach, A. 226, 84). The p-isomeride, [100°], (310°), is got in like manner from hydroquinone (Bender, B. 13.697

PHENYLENE-CHLORO-OXY-ACETYLENE RETONE v. CHLORO-DI-OXY-INDONAPHTHENE. PHENYLENE - CINNAMYLIDENE -

METHYL DI AMINE C_{1,H in}N, i.e. C_{1,H in}CH::OH::OH::OH::N.O₅H₁,NMo₂. [141°]. Formed from cinnamic aldehyde and phenylene-dimethyl-p-diamine (Nuth, B. 18, 575). Needles.

methyl-p-diamine (Num, p. A., 515). Assausa PHÉNYLENE - CUMINYLIDENE - DI -METHYL-DIAMINE C, H, N, i.e. C,H,C,H,CH:N.C,H,NMe₂. [100°]. Formed

from cuminol and phenylene-di-methyl-diamine (Nuth, B. 18, 575; Uebel, A. 245, 299). Needles. 202-PHENYLENE DICYANATE CoH4(N:CO).

[51°]. Got by distilling m phenylene-dicarbamic

[91], Got by assitting m-phenylene-distribution cher (Bender, Bn. 3, 897). Crystals.

p-PHENYLENE DI-CYANATE C.II. (N:C:O)...
[91]. (231° at 745 mm. i.V.). V.D. 5.79 (for 5-54). Prepared by passing a stream of carbonyl chloride COCl. through p-phenylene-diamine hydrochloride heated to 200°-250° (Gatter-mann a. Wrampolmagar R. 18, 2604). mann a. Wrampelmeyer, B. 18, 2604). Coloure less modles less needles. Sublimable. Pungent vapour. Reacts like phenyl-cyanate, forming di-ureas with amines, and di-carbamic ethers with alcohols.

PHENYLPNE DI-CYANIDE v. Nitrile of PHTHALIC ACU

PHENYLENE ETHYL-ACETAMIDINE

 $C_eH_i < NE_N^{NE_i} > C.CH_i$. [180°]. Formed by the action of Ac.O on phenylene-ethyl-o diamine [C.H.(SO.),C.H., Formed by heating ethylen (Hompel, J. pr. [2] 39, 200; 41, 166). Plates.

PHENYLENE-ETHYL-O-BIAMINE C.H.(NH.)(NHEt). (249°). Formed by reducing o-nitro-ethylaniline with tin and MCl (Hempel, J. pr. [2] 39, 199; 41, 164). Oil,

turning red in air and light.

Acetyl derivative C.H.N.EtAc. [104°]. Phenylene ethyl-m-diamine

C, H, (NH,)(NHEt). (276° uncor.). Oil, formed in like manner (Nölting a. Stricker, B. 19, 546). B"H_Cl,: white powder.

Ehenylene ethyl-p-diamine. (270°). Oil, sol. bonzene (Nölting a. Collin, B. 17, 267; Schweizer, B. 19 149; Facher a. Hepp, B. 19, 2994; Bernthsen a. Goske, B. 20, 930).-B"II,SO,: needles or prisms.—B"H,Cl2. Plates,

v. sol. water.—B"H₂PtCl₈.
Phenylene-di-ethyl-m-diamine

C.H.(NH.) (NEt.). (277°). Formed by reducing m-nitro-di-ethyl-atfiline (N. a. Se; Groll, B. 19, 200). Gil.

Phenylene-di-ethyl-p-diamine. (261° un-cor.). Formed by reducing nitroso-diethyl aniline or C₆H₄(NEt.).N₂.C₆H₄.NEt₂ (Lippmann a. Fleissner, B. 16, 1424). Oil.—B'H.I.Cl.PtCl₄. Red crystals.—B"ZnCl, 2aq. Converted by treatment in aqueous solution with alaminium sulphate, Na₂S₁O₃, and K₂Cr₂O₇, into NEt₂.C₈H₃(NH₂).S.SO_.H [229°], whence by diazotisation $C_0H_3(NEt_2) < \frac{N_2}{S^2}$ [107°] may be got

(Bernthsen, A. 251, 1). Phenylene-s-di-ethyl-p-diamine.

Nitrosamine C,H,(NEt.NO)2. [90°]. Formed from p phenylene-diamine by successive treatment with EtBr and HNO. (Nietzki, B. 16, 465). Yellowish plates (from benzene-ligroin).

Phenylene-tetra-ethyl-p-diamine C,H₄(NEt.)₂. [52°]. (280° uncor.). Got by heating phenylene-di-ethyl-diamine or N₂(C₆H₄.NEt.)₂, with Etl (Lippmann a. Fleissner, B. 16.1427; M. 4, 301. Manoclinic plates (from dilute alcohol), a:bcc = 99:1:1-833; β = 90-30′.—B″ILPtCl.—B″ILHg.Cl. Monoclinic prischs.—B″_L:black prisus.—B″HI.—B″HI.—PHENYLENE-ETHYL BENZAMIDINE

 $C_sH_i < NE_N^{NE} > CPh.$ [81°]. Got by ethylation of phenylene-benzamidine (Howe, Am. 5, 421).— B'HCl 3aq.—B'.H.PtCl.,—B'HNO, aq. [155°].— B'EtOH [136°].—B'EtI aq.—B'EtCl 2aq.— B',Et,PtCl... B'EtHSO, aq.

PHENYLENE-ETHYLENE-o-DIAMINE

C_sH_s
 NH.CH₂ Quinoxaline tetrahydride.

 [97°]. (290°). V.D. 4.44 (calc. 4.64). Formed

by heating pyrocatechin with ethylene-diamine hydrate at 200°-210° (Merz a. Ris, B. 20, 1191). Formed also by reducing quinoxaline with alcohol and Na. Plates (from water). FeCl, colours its dilute aqueous solutions blue or violet. Alkaline K_LFeCy, oxidises it to quinoxaline.—B",3HCl. [above 150°]. Scales.—B"₂H₂C₂O₂. [184°].—B"₂2C₂H₂N₃O₂. [above 120°]. Yellow crystal.

line.pp., sl. sol. ether.

Acetyl derivative C.H.:N.Ac.:C.H...
[144°]. [350° uncor.). Granules, sl. sol. cold water Di-phenylene-ethylene-tetramine wol, ii.

p. 491. PHENYLENE-ETHYLENE-DISULPHONE bromide with potassium benzene m-disulphinate

(Otto, J. pr. [2] 36, 450). White plates, m. sol. conc. HNO...

PHENYLENE DI-ETHYL DIKETONE

C_sH₄(CO.C₂H₅)₂. [220°). Formed from terephthalic chloride and ZnEt₂ in ether (Münchmeyer, B. 19, 1850). Needles (from ether).

PHENYLENE DI-ETHYL DISULPHONE C₆H₄(SO₂Et)₂ [142°]. Obtained by heating C₆H₄(SO₂K)₂ [1:8] with EtBr at 100° (Otto, J. pr. [2] 36, 449). Colourless plates.

PHENYLENE-FURFURALDEHYDINE .v. vol. i. p. 109. .

PHENYLENE-DIGLYCOLIAC ACID v. Oxy-DIPHENYLENE-ACETIC ACID.

DIPHENTLENE-DIHYDRAZINE C12H14N4 t.e. N.H., C.H., C.H., N.H., [167°]. Formed from benzidine hydrochloride by diazotisation and reduction by Na.SO, or SnCl. (Arheidt, A. 239, 206). Small white plates, sol. hot water. Aqueous potassium cyanate forms the semicarbazide $C_{11}H_{16}N_{\circ}O_{2}$ [307°]. Nitrous acid forms a dinitrosamine $C_{12}H_{13}N_{\circ}O_{2}$ [112°]. Pyruvicacid forms $C_{11}H_{14}N_{\circ}O_{2}$ [197°]. Acetone yields $C_{11}H_{13}N_{\circ}O_{2}$ [198°], whence fusion with ZnCl. yields diphenyl-di-methyl-indole $C_{11}H_{16}N_{\circ}$ [270°]. Reference. - DI-OXY-DI-PHENYLENE DIHYDRAZ-

INE.

DIPHENYLENE-IMIDE v. CARBAZOLE. DIPHENYLENE KETONE

[83°]. (above 300°).

Formation. -1. By distilling phenanthraquinone or diphenyl di-o-carboxylic acid with CaO (Fittig a. Ostermayer, A. 166, 373; Anschutz a. Schultz, B. 9, 1400).—2. By heatoing anthraquinone with lime (Anschütz, B. 11, 1213). - 3. By dry distillation of the Ag salt of 1213.—5. By any distination of the Ag Sant of its dicarboxylic acid. (Bamberger a. Hooker, B. 18, 4034; Ar 229, 156).—4. By passing a mixture of phenol and CS₂ over hot copper (Carnelley a. Dunn, C. J. Proc. 4, 53; B. 21, 2005, who regard the product thus obtained as incompatible). isomeride).

Properties.—Yellow needles or plates (from alcohol). Yields phenyl-benzoic acid by potashfusion. Distillation over zinc-dust gives diphenylene-methane [113°] (Fittig, B. 6, 187). Forms a nitro derivative [220°] and a di-nitro-distinction [200°] (Fittig, B. 6) 202. [104]. derivative [290°] (Schultz, A. 203, 104). Alkaline KMnO, oxidises it to phthalic acid (Anschütz a. Japp, B. 11, 213). H.SO, forms at 260° a disulphonic acid, whence CaA" (Schmidt a. Schultz, A. 207, 345).

Oxim. [192°] (Spiegler, M. 5, 195).

References .- BROMO-, DI-CHLORO-, NITRO-, and

OXY, DIPHENYLENE KETONE.
DIPHENYLENE KETONE CARBOXYLIC **ACID** [1:2] $C_sH_s < \frac{CO}{2} > C_sH_s$. $CO_sH \begin{bmatrix} 1 \\ 2 \end{bmatrix}$. [192°]. Formed by oxidation of fluoranthene by chromic acid mixture (Fittig, A. 193, 149; 200, 6).

Orange-red needles (from dilute alcohol).

Reactions.—1. Potash-fusion gives diphenylom-dicarboxylic acid.—2. Yields diphenylom ketone on distillation.—3. Distillation with zincdust gives diphenylene-methane (fluorene).

Salts. - BaA', 4aq. - CaA', 2aq. - AgA'. Diphenylane ketone carboxylic acid. [above 275 . Formed by heating the dicarboxylic acid (Bamberger a. Hooker, B. 18, 1034; A. 229, 158). Pale yellow needles, sl. sol. alcohol. May be sublimed.—BaA'₂.—AgA': yellow pp. Diphenylene ketone carboxylic acid

[1:2] $C_{e}H_{e} < {}^{CO} > C_{e}H_{e}$. $CO_{e}H \left[{}^{1}_{2} 5 \right]$. [227° cor.].

Formation (Graebe, B. 13, 1303; B. 20 845; A. 247, 275).—1. From diphenyl di oozo; A. 24', 275).—1. From diphenyl dio-carboxylic acid by heating with H₂SO₄ at 120° or with POCl, or ZnCl₂.—2. By heating di-phenylene dicarboxylic acid with H₂SO₄ for 10 minutes at 150°.

Properties.—Yellow needles, v. sol. hot al-cohol. Conc. H₂SO₄ forms a red solution.

Receives.—1 Patch freque with dishard.

Reactions.—1. Potash-fusion yields diphenyl di-o-carbonylis acid.—2. PCl. (1 mol.) forms C.H. (COCI) CO [128°], which may be crystalelised from ligroin.—3. PCl_s (2 pts.) at 160° yields C₆H₄(COCl) CCl₂ [95°], which yields fluorene carbexylic acid on reduction with zincdust and dilute acetic acid. 4. Zinc-dust and ammonia reduce it to C₈H₃(CO₂H)>CH(OH).— 5. HI and P give fluorene. 6. Phenol and SnCl₄ at 120° give $C_{0}^{0}H_{1}(CO_{0}H)$ $C(C_{0}H_{1}OH)_{2}$ $C(C_{0}H_{1}OH)_{2}$ $C(C_{0}H_{1}OH)_{2}$ $C(C_{0}H_{2}OH)_{3}$ $C(C_{0}H_{2}OH)_{3$ C.H.-C₀H₂(CO₂H)>C(C₀H₂(OH)₂)₂, a yellowish-brown powder which exhibits green fluorescence in alkaline solutions.

alkaline solutions.

Salts. — NH₄A' aq. — NaA' 6aq: yellow needles, v. sol. hot water.—AgA': yellow pp.

Methyl ether MeA'. [132°]. Needles.

Ethyl ether EtA'. [103°]. Needles.

Chioride C₁₄H,ClO₂. [128°].

Amide C₁₄H,(NH₂)O₂. [225°]. Silky yellow needles (containing hOEt). Formed from the chloride, and also by heating phenanthraquinone monopoxim with H₂SO₄ at 100° (Wegerhoff, B. 21. 2357). 21, 2357).

Oxim C₁₄H,(CO₂H)(C:NOH). [263°].

Phenyl-hydrazide C₁₄H₂(CO₂H)(C:N₂HPh). [205°]. yellow prisms, m. sol. alcohol.

Diphenylene ketone dicarboxylic acid C_eH_s CO $C_eH_c(CO_2H)_z$ $\begin{bmatrix} 1\\23:6 \end{bmatrix}$. Formed by oxidation of retene-quinone and of oxyisopropyldiphenylene-ketone carboxylic acid (Bamberger a. Hooker, B. 18, 1033; A. 229, 151). Yellow needles (from HOAc). Not melted at 270°, but loses CO, at a higher temperature. Yields diphenyl on heating with CaO. Potash-fusion forms diphenyl tricarboxylic acid.—BaA".—

Ag.A": yellow pp. Methyl ether Me,A". needles.

Ethyl ether EtA". [115°]. Needles. Oxim C12Ha(CO2H)2:C(NOH). Yellow pp., not melted at 250°

DIPHENYLENE KETONE OXIDE

 $CO < \stackrel{C_uH_1}{C_uH_1} > 0$. Xanthone. [174°]. (350°) at 730 mm. (Graebe, A. 254, 280). S. (alcohol) .7 in the cold; 8.5 at 78°.

Formation .- 1. Obtained by oxidation of $CH_{2}C_{2}H_{4}>0$ with CrO_{3} and HOAc (Me z a.

Weith, B. 14, 192) .- 2. By the dry distillation of salicylide; the yield being 35 p.c. of the theoretical (Perkin, B. 16, 339). -3. By distilling phenyl phosphate with sodium m- or p-oxybenzoate (Richter),—4. By the action of POCI, on potassium-salicylate of ethyl.—5. By distilling neutral or basic sodium salicylate with P₂O₅.—6. In small quantities, when salicylic acid is distilled.—7. By strongly heating sodium o-chlorobenzoate.—8. From sodium o-phenyl-benzoate and POCl₂.—9. To the amount of 12 p.c. of the theoretical quantity, by the action of o-chlorobenzoyl chloride on basic sodium salicylchlorobenzoyl chloride on basic socium sancyinate.—10. By the action of cone. H_SQ, on 11:2] QH_QOPh_CO_H (Graebe, Z. 21, 563).—11. By distilling phenyle salicylate (Seiffert, J. pr. [2] 31, 479).—12. By heating salicylic acid (1 mol.) with PCl, (1 mol.), then adding phenol and distilling (Klepl, J. pr. [2] 28, 217.—13. By distilling calcium p-oxy-benzoate Gold-sheriet M A 1981—14 A mothet of the elecschmidt, M. 4, 128).-14. A product of the electrolysis of a solution of phenol in KOHAq at 200° (Bamberger a, Berlé, B. 24, 3212).

Preparation.—1. Phenyl phosphate (20 g.) and sodic salicylate (20 g.) are distilled together; a violent action ensues; when it is over the residue is distilled over at 400°, best in a current of air. The crude product is shaken with solu-tion of NaOH and distilled with steam. The residue is extracted with alcohol, from which, on cooling the ketone crystallises (R. Richter, J. pr. [2] 28, 276).—2. By distilling salicylic acid with Ac₄O, the salicylide which is first formed splitting off CO2 when the temperature rises (Perkin, C. J. 43, 35). In this process there is formed a by-product $C_{14}H_{\pi}O_{3}$ [192°] which is converted by boiling alcoholic potash into an acid C14H,O4 [275°] (A. G. Perkin, C. J. 43, 187).

Properties.—Long white needles, grouped concentrically. M. sol. ether, alcohol and benzoline, more sol. benzene and chloroform, insol. water. The solution in conc. H.SO shows blue fluorescence (Graebe, B. 15, 1679). Does not react with hydroxylamine or phenyl-hydrazine (Spiegler, B. 17, 808).

Reactions.—1. Reduced by zinc-dust or by HI to CH₂ C_cH₄ O [100.5°] but no further.—

2. Potash-fusion converts it into salicylic acid and phenol.—3. If the fusion be stopped when the mass is pasty (at about 200°), dissolved in water and ppd. by HCl, di-oxy-benzophenone is obtained, CO(C_aH₁OII)₂—4. Sodium-amalgam reduces the di-phenylene-ketone oxide (in dilute alcoholic solution) to C₂.H₁₈O₃ [200°]. This body crystallises from CHCl₃ in prisms. It is split up by chromic acid into di-phenyleneketone oxide and diphenylene methane oxide, so that it is perhaps a molecular compound of these two bodies. - 5. Bromine at 200° forms a fibromo- derivative [212°]. — 6. Furning H.SO. gives a disulphonic acid which forms BaA" aq,

A product of the action of POCl, on sodium salicylate (Richter, J. 2r. 12). 28, 294). Formed selective Richter, J. 2r. [2] 28, 294). Formed selective Richter, J. 2r. [2] 28, 294). Formed selective Richter, J. 2r. [2] 28, 294). also by heating the sulphate of o-diazobenzoic o acid with phenol (Griess, B. 21, 981). Needles, .v. e. sol. ether. Yields diphenyl on distillation | Needles, sl. sol. cold alcohol, v. e. sol. CHel.

with zinc-dust. Br gives C, H, BrO, [1980]. H.SO, yields a disulphonic acid, which gives BaA"aq crystallising in needles.

Dixanthone • C₆H₄ < O_{CO} > C₆H₂ < O_{CO} > C₆H₄.

[256°]. Occurs in the product of the action of salicylic acid on resorcin (Kostanecki a. Seidmann, B. 25, 1654). It crystallises from HOAc in groups of needles, and its solution in H.SO. shows greenish fluorescence.

eReferences. - DI-AMIDO-, NITRO-, and Oxv-

DI THENYLENE RETONE OXIDE.

PHENYLENE MERCAPTAN v. DI-THIOBESORCIN BUILD DI-THIO-HYDROQUINONE.

Diphenylene mercaptan C.H.(SH).C.H.(SH). [176°]. Formed by diazotising benzidine, and treating the product with potassium xanthate and alcoholic petash successively (Leuckart, J. pr. [2] 41, 212; cf. Gabriel, B. 13, 390). White plates (from alcohol).

Di-methyl ether $\text{Me}_2\text{A''}$. [184°]. Plates. Di-ethyl ether $\text{Et}_2\text{A''}$. [135°]. Plates. 00-DIPHENYLENE-METHANE v. FLUOR-ENE.

(9) - Diphenylene - methane CH₂ C₀H₁.

Methylene-diphenyl. [118°]. (295° uncol.). V.D. 84 (calc. 83). Occurs, together with the (8)immeride, among the products of the passage of a mixture of benzene and toluene through a red-hot tube (Carnelley, C. J. 37, 708). Pearly plates (from alcohol), sl. sol. cold alcohol, v. sol. ether. . Its alcoholic solution shows faint blue fluorescence. CrO₃ and HOAc oxidise it to $C_{13}H_{\gamma}O_{2}$ [281° cor.]. Bromine in ether gives $C_{13}H_{\gamma}B_{T_{2}}$ [162°]. Pieric acid forms a compound $C_{13}H_{\gamma}G_{2}H_{\gamma}N_{2}O_{\gamma}$ crystallising in blood-red needles relief

(3)-Diphonylene-methane $C_{13}H_{10}$ [205°]. (320°). V.D. 86.2 (cala 83). Formed as above. Pearly plates (from alcohol). Oxidised by CrO3 in HOAc to C12H3O2 [2889 cor.] which sublimes in white needles.

DIPHENYLENE-METHANE OXIDE

 $\text{CH}_2 < \frac{\text{C}_8 \text{H}_4}{\text{C}_8 \text{H}_4} > \text{O}$ [100°]. (315° cor.). Formed, to the amount of 2 p.c., in the preparation of Ph.O by heating phenol with AlCl, (Merz a. Weith, B. 14, 191). Formed also from di-Wetti, B. 12, 121). Formed also from diphenylenc ketone oxide by heating with fuming HIAq at 160° or by distilling with zinc-dust (R. Richter, J. pr. [2] 28, 280; Graebe, A. 254, 282); and by distilling envanthone over heated zinc-dust (Wichelinaus a. Salzmann, B. 10, 1399; Graebe a. Ebrard, B. 15, 1678). White plates (from alcohol).

plates (110m alconol).

Reactions.—1. Oxidised by CrO₂ or dilute
HNO₃ to diphenylene ketone oxide.—2. PCl₁
'forfis HCl and a product whence water at 0°
produces C₁₁H₂O.PO(OH), [255°-260°] an acid
forming Ag,A" and (NH₁),A".—3. Br forms
C₁₂H₂Br₂O and C₁₃H₃Br₂O [136°].

DIPHENYLENE - METHANE SULPHIDE CH, C, H, S. [128°]. (342°). Formed by reducing CO $\stackrel{\text{C}_{\circ}H}{\stackrel{\text{C}_{\circ}H}{\stackrel{\text{N}}{\sim}}}$ S with HI and $\stackrel{\text{P}}{\text{P}}$ at 170°; and also by passing phenyltolyl sulphide through a red-hot tube (Graebe a. Schultess, A. 263, 12).

DIPHENYLENE - METHANE SULPHONE CH CH SOr [170°]. Formed by heating CO C.H. SO, with HI and P at 170° (Graebe a. Schultess, A. 263, 15). Needles, v. sol. hot

PHENYLENE-METHENYL-AMIDINE

 $C_{\bullet}H_{\bullet} < NH > CH$. [167°]. (above 360°). Formed by boiling phenylene-o-diamine with formic acid (Wundt, B. 11, 826; Fischer, B. 22, 645). Trimetric crystals (from alcahol).-B'HCl aq. Yields on methylation C,H,N, [33°] (278° at 730 mm.).

Carboxyfic acid $CO_2H.C_eH_3 < NH > CH.$ Formed by reducing the formyl derivative of (2.1.4)-nitro-amado-benzoic field (Zehra, B. 23, 3634). White needles, blackening without fusion when heated.—HA 'HCI: white needles.

***m - PHENYLENE - METHYL - DIAMINE**

[1:3] C.H. (NH2).NHMe. . Methyl - phenylene diamine. •Amido-methyl-aniline (265°-270° uncor.). Formed by reduction of m-nitromethyl-aniline (Nölting a. Stricker, B. 19-548). Oil. Gives a methyl-chrysoïdine with diazo-benzene chloride.

p-Phenylene-methyl-diamine

[1:4] C,H,(NH,2)(NHMe). (258° uncor.). Formed by reduction of p-nitroso-methyl-aniline (Fischer, B. 19, 2992) or of C₆H₄(NHMe).N₂.C₆H₄.SO₃H₄ (Bernthsen a. Goske, B. 20, 929). Oil, v. sol. water. FcCl, gives a red colour, which on successive treatment with HCl and H.S becomes blue (dimethylthionine). - B'2H2SO4: white needles (from water).

m-Phenylene-di-methyl-diamine

[1:3] C_aH₁(NH_a)(NM_{e.}), (269°) at 740 mm. S.G. ²³ 995 (Groll, B. 19, 200); (258°) (Staede a. Bauer, B. 19, 1945). Formed by reduction of m-nitro-di-methyl-aniline. Oil. With nitrous acid it yields a colouring-matter closely resembling Bismarck brown. With diazobenzene effloride it yields a di-methyl-chrysoïdine which dies a somewhat redder shade than chrysoïdine. PbO₂ and aqueous HOAc gives a yellowish-brown colour (Lauth, C. R. 11, 975).—B'HCl. Acetyl derivative C₈H₄(NMe₂)(NHAc).

p-Phenylene-di-methyl-diamine [1:4] C₆H₄(NH₂)(NMe₂). [41°]. (257° i.V.). 11:19 U_nH₁(NM_c) [41"]. (257° i.V.). Prepared by reduction of nitroso-di-methyl aniline and of (C₀H₁NM_c)₂N₂O by tin and HCl (Schraube, B. 8, 616; Wurster, B. 12, 522; Weber, B. 10, 760). Prepared also by reduction of C₀H₁(NM_c)₂N₂O₂H₄(SO₂H₄(E. Fischer, B. 16, 235.6) 2255). Formed also together with di-chloro-pphenylene-diamine and di-chloro-p-phenylene-di-methyl diamine by boiling nitroso-di-methyluniline with HCl (S.G. 1.2) (Möhlau, B. 19, 2010).

Properties.—Long white needles or short prisms, v. sol. water, alcohol, and ether. PbO₂ and aqueous GOAc give a magenta-red solution changing to violet-black (Lauth, C. R. 111, 975).

colours wood, and paper made from wood, erimson (Wurster, B. 20, 808).

Reactions.—1. Yields quinone on oxidation with MnO and H.SO,—2. Bromins in HOAc forms C,H11N2Br, which crystallises from its red

alcoholic solution in green scales [146] (Wurster a. Sendtner, B. 12, 1803).-3. H₂S and an oxidising agent (e.g. FeCl.) gives methylene-blue (v. vol. ifi. p. 265). Methylenered S₂ $\stackrel{C_aH_3}{N}$ NMe₂CP is a by-product (Bernthsen, A. 230, 137; 251, 1).—4. Na₂S₂O₃ and CrO, give C.H. (NMe.) (NH.) S.SO.H, which yields methylene-blue on further oxidation. 5. Aldehydes and ketones form products of condonsation, e.g. C.H. (NNc.), N:CHPh (937) (Calm, B. 17, 2939), C.H. (NNe.), N:CH.C.H. (0H [1:2] [1342], and C.H. (NNe.), N:CH.C.H. (OMe [1:4] [134°], and C_aH₄(NMe₂).N:CH₄C₃H₄OMe [1:4] [148°] (Nuth, B. 18, 574; Steinhart, A. 241, 344). Benzil and alcoholic KOH form CPhBz:N.C_aH₄NMe₂ [139°]; benzoyl-acetone forms in like manner CH₄Bz,CMe:N.C_aH₄NMe₂ (136°] (Vogtherr, B. 25, 635). Benzoin gives CHPh(OH).CPh:N.C_aH₄Ne₂ [127°] on heating, while deoxybenzoin forms C₂₇H₂₂N₂ [139°].— 6.0Cxalic coher forms, on heating, the ether C_aH₄(NMe₂),NH.CO.CO₂Et [117°] which yields California (192°) and amide [259°] (Sendther, B. 12, 530).
Salts.—B"2HCl. Very deliquescent plates.
—B"H_SnCl. Cubes.—B"H_PtCl.,
Actyl derivative CaH_(NMe_)(NHAc).

[130°]. (855°). Small leaflets or needles.

p-Phenylene-tri-methyl-diamine [1:4] C₆H₄(NMe₂)(NMeH). (265°). Obtained by reduction of its nitrosamine, which is formed by the action of nitrous acid on p-phenylene-tetramethyl-diamine (Wurster a. Schobig, B. 12, 1809). Oil.

Acetyl derivative. [95°]. Prisms. Nitrosamine CoH4(NMe2)(NMe.NO). [99°]. Leaflets or tables, sl. sol. cold water.

m-Phenylene-tetra-methyl-diamine [1:3] C_aH₄(NMc₃)₂. [-2°]. (266° i.V.). S.G. ¹²
992. Prepared by heating phenylenc-m-diamine with methyl alcohol and HCl at 190° (Wurster a. Morley, B. 12, 1814). Purified by distilling with Ac₂O (Romburgh, R. T. C. 7, 2). Oil, sl. with Ac₂U (Romburgh, R. T. C., 1, 2). OII, si. sol. water. HOAc and nitric acid give C₈H(NO₂),N₂Me₄NO [132°]. s-Tri-nitro-benzene forms B"C₈H₄(NO₂), [121°] m.Di-nitro-benzene gives B"C₈H₄(NO₂), [158°] crystallising in needles. Bromine forms oily C₈H₄(NO)(NMe₂), which forms a hydrochloride B'HCl, crystallising in Jeck red needles (Witt R 18 R77) dark-red needles (Witt, B. 18, 877).

Salts.—B"H,Cl, 2aq: hygroscopic crystals. B"H,FeCy, aq. Pearly plates (Wurster a. -B"H, FeCy, aq. Roser, B. 12, 1826).

Methyliodide B"Mel. [192°]. Crystals. v. sol. water .- B"MeHI2.

Di-methylo-di-iodid B"Mc,I, Plates, v. sol. water (Hofmann, Pr. 12, 639).

p-Phenylene-tetra-methyl-diamine [1:4] C₀H₄(NMe₂)₂. [51°]. (260° i.V.). Prepared by heating p-phenylene-di-methyl-diamine with MeOH and HClAq at 200° (Wurster, B. 12, 526, 1803, 1827). White leaflets, sl. sol. cold water, v. sol. alcohol. Its aqueous solution becomes violet-blue on exposure to air ar addition of oxidising agents. The blue substance appears only to exist as a salt, e.g. C.H. NMe, Cl NMe, Cl NMe - CH, (Wurster, B. 19, 3195; 20, 256; 21, 921). It becomes colourless on further oxidation.

Reactions .- 1. Bromine in HOAc forms a

blue colouring matter C, H, N, which forms blue solutions in water and alcohol.—2. K, FeCy, added to a solution of the sulphate forms C₁₆H₁₄N₂2H₄FeCy₆ crystallising in lustrous blue needles. — 3. Sodium nitrite and hydrochloric needles. — 5. South series and hydrodanacid give C.H. (NMs.) (NMe.) (N EMO.) [98°] at C.H. (NO.) (NMs.) NMe.NO [87°].

Salts.—B"2HCl; crystals.—B"H_2PtCls.

B"2H_5O..—B"H_FeCys: white needles. [98°] and

Methylo-iodides B"Mel. [above 270°]. Leaflets (W.).—B"Me₂L. Plates (Hofmann). Reference. - NITRO-PHENYLENE-DI-METHYL-DI-AMINE.

PHENYLENE - DI - METHYL - DI - AMINE SULPHONIC ACID C,H,(NH,)(NMe,).SO,H. Got by reduction of p-nith-di-methyl-amido-benzene sulphonic acid (Michler a. Walder, B. 14, 2176). Large rhombohedra, v. sol. water. BaA' - CaA' : plates.

-PHENYLENE-DI-METHYL-DI-ETMYL-DIAMINE C.H. (NMe.) (NEt.). (2672). Formed from [1:4] C.H. (NEt.) (NH.). McOH, and HCIAq at 200° (Lippmann a. Fleissner, M. 4, 791). Liquid. Coloured blue by oxidising agents.

Methylo-iodide B"2Mel. [218°]• Yields B"Me₂PtCl_e, B"Me₂AuC B"Me₂(C₄H₂N₃O₇)₂ [235°]. B"Me2AuCl, B"Me2CdI,

o-PHENYLENE - METHYL - ETHYLENE -DIAMINE C.H. NII C.H. v-Methyl-quin-

exaline tetrahydride. (274°). Formed by heating phenylene-ethylene-diamine with MeI at 110° (Ris, B. 21, 381). Liquid. Its aqueous solution is coloured blue by FeCla.

Methylo-iodide B'MeI. [above 200°]. Crystals.—B',Me,PtCl. Yellow needles.

DIPHENYLENE - METHYL - FURFURANE C.H..C.O.CMe. Got by reducing C.H., C(OH).CH, Ac (Japp a. Klingemann, B. 21, 2932).

PHENYLENE - DI - METHYL - DI - MALONIC **ACIDS** C.H. $(CH_1,CH(CO_1H)_2)_T$ The ethers of these acids are formed by the action of zincdust on the acids $C_4H_1(CH_2,CCl(CO_2Et)_2)_2$ which are formed from sodium chloro-malonic ether and a-di-bromo-xylenes (Perkin a. Kipping, C. J. 53, 16; B. 19, 437; 21, 36). The o- and methers are oily, the p- ether is crystalline [51°]. The ethers form deliquescent sodium derivatives Na₂C₂₂H₂₂O₂, and the o-compound of this formula is converted by iodine into the tetrahydride of naphthalene tetracarboxylic ether. The macid is a liquid v. sol. water, the p-acid is crystalline [1959]. The p-acid forms Ag,A", and when heated splits up into CO, and C,H,(CH,CH,CO,H), [223°].

PHENYLENE - METHYL - METHENYL -AMIDINE C.H. $\langle N_N^{Me} \rangle$ CH. [33°]. (278°) at Formed from phenylene-methenylamidine, Mel, and McOH at 100° (O. Fischer, B. 22, 644). Prisms.—B'HAuCl., Needles.

DIPHENYLENE-METHYL-PYRAZINE C_4H_1 C.N:CMe C_4H_4 C.N:CH . [128°]. Formed from phenanthraquinone and propylene-diamine (Strache, B. 21, 2362). White needles.—B'_*H_PtCl_*.

p-p-DIPMENYLENE. TETRA. METHYL. DI. PYRROLE Ca.H. N. i.e. CH:CMe N.C.H.C.H.N CMe:CH •[150°]. Got by heating an alcoholic solution of acetonylacetone (2 mols.) and henzidine (1 mol.) (Paal a. Schneider, B. 19, 3158). Colourless tables. Sol. alcohol, ether, benzene, and ligroin.

DIPHENYLENE-METHYL-QUINOXALINE $C_{2i}H_{1i}N_{2}$ i.e. $C_{o}H_{1}Me < \stackrel{N:C.C_{o}H}{N:C.C_{o}H}$. [213°]. Formed from (1,3,4)-tolylene-diamine and phenanthraquinone in HOAc Hinsberg, B. 17, 323). Yellow hair-like crystals, v. sol. benzene.

DIPHENYLENE - NAPHTHOQUINOXAL . INE $C_{io}H_{\bullet} < \stackrel{N:C.C_oH_{\bullet}}{N:C.C_oH_{\bullet}}$. [273°]. Formed by boiling an alcoholic solution of (1,2)-naphthylene diamine with phenanthraquinone in HOAc (Lawson, B. 18, 2426). Small yellow crystals.

The sulphonic acid, got by mixing a hot

aqueous solution of naphthylene-o-diamine sulphonic acid with phonanthraquinone dissolved in NaHSO, Aq with addition of NaOAc, forms a yellow crystalline Na salt, sol. hot water, but ppd. By alkalis (Witt, B. 19, 1719, 2701). When fused with KOH it yields the insoluble eurhodol $C_{12}H_s < N > C_{10}H_s(OH) \begin{bmatrix} 1 \\ 2 \end{bmatrix}$, which forms a scarlet hydrochloride.

m - PHENYLENE - DI - (β) - NAPHTHYL -DIAMINE C.H.(NHC,,H), [126]. Formed by heating m-phenylene-diamine with (8)-naphthol (Ruhemann, B. 14, 2651). Felted needles, sol. alcohol and ether.

needles, sol. alcohol and collection.

p.Phenylene-di-(β)-naphthyl-diamine
C_sH_s(NHC₁₀H_s)... [235°]. (over 400° in vacuo). Collection of the collect plates, almost insol. boiling alcohol, v. sol. nitro-benzene. KNO₂ added to its solution in conc. H., SO, gives a egreenish wickt colour, changing to blue, B'2C, H., N,O. [c. 217].

Acetyl derivative C, H., (NAc. C, eH.), [210]. Plates (from benzene).

0°]. Plates (from benzede).

Benzoyl derivative C₂₂H₁₄Bz₂N₂. [220°]. Reference. - NITRO-PHENYLENE-NAPHTHYL-DI-

AMINE. PHENYLENE - NAPHTHYLENE - AMINE

C₁₈H₁₁N i.e. [1:2] C₈ H₁ NH. Phenyl-naphthyl-carbazole. [3:3] C₁₉H₂ NH. Phenyl-naphthyl-(35) S. (alcoh.l.) 25 at 78°; S. (toluene) ·5 at 111° (Bechi, B. 12, 1978). Occurs in crude anthracene, from which it may be got from the residues after sublimation of the anthracene (Graebe a. Knecht, B. 12, 341, 2242; A. 202, 1). Formed by passing phenyl- (β) -naphthyl-amine through a red-hot tube. Colourless plates, v. sl. sol. HOAc. Its solutions show blue fluorescence. Oxidation by K2Cr2O, and H2SO, forms the Oxidation by $n_{\rm cons}$ NH [307°] which crystallises from HOAc in reddish-yellow needles, and is accompanied by $C_{\rm is}H_{\rm io} > 0$ which crystallises from benzene in red prisms. 0

Moetzeld derivative C₁₈H₁₂NO. [121°]. Nitrosamine C₁₈H₁₈N₂O. [210°]. Tetrahydride C₁₈H₁₈N. Formed Formed by reduction with HIAq and P at 210°. Syrup. B'HI. Long needles.

Theaylene-naphthylene-amine

[1:2] C, H NH. [225°]. Formed by heating SCO H NH with reduced copper at 240° (Kym, B. 23, 2465). Greenish-yellow plates, sl. sol. cold benzene, v. sol. hot alcohol.

PHENYLENE - NAPHTHYLENE - RETONE

oxide CO CoH O. [155°]. Formed by boiling (a)-naphthy salicylate (Graebe a. Feer, B. 19, 2612). Formed also by heating (a)-naphthol with salicylic acid and HOAc; and by distilling (1,2)-(α)-naphthol carboxylic acid with salicylic acid (Kostanecki, B. 25, 1643). Crystals, sl. sol. cold alcohol. Its solution in H2SO4 shows green. Converted by potash-fusion into fluorescence. Converted by potash-fusion into o-(α)-di-oxy-phenyl-naphthyl-ketone (Phomina,

A. 257, 92) Isomeride. [140°]. Formed in like manner from (β)-naphthyl salicylate; and by heating (2.1)-(8)-naththol carboxylic acid with salicylic Needles. Reduced by zinc-dust acid.

CH. C. H. O. [80°].

p. PHENYLENE-DI (3) - NAPHTHYL - DI -METHYL DIAMINE C₄H₁(NMe.C₁₀H₁)... [180°]. Formed from C₄H₄(NHC₁₀H₁)... MeI, and Me⊕li at 140° (Rueff, B. 22, 1080). Plates.

PHENYLENE - NAPHTHYLENE C, H, O. [178°]. Formed by distilling a mixture of phenol and (a)-naphthol with PbO (Arx, B. 13, 1726; A. 209, 141). Yellow needles, sl. sol. alcohol. H.SO, forms a tetrasulphonic acid which gives Ba₂C₁₆H₄S₂O₁₇4aq. CrO₃ and HOAc form C₁₆H₄O₂ [140°].—C₁₆H₄O₂C₂H₄N₃O_. [165°].

Isomeride C₁₆H₁₉O. [296°] (A.); [300°] (G. a. K.). Formed in tike manner from (β)-

naphthol (A). Got also by distilling the compound C₁₀H₂O₃ (from phenylene-naphthylene-amine) with zmc-dust (Graebe a. Knecht, A. 202, 15). Plates x. sol. toluene.

References.—DI-BROMO-, DI-GRIGORO-, and DI-

NITRO- PHENYLENE-NAPHTHYLENE OXIDE.

PHENYLENE OXIDE C.H.O? [103°]. A product of the distillation of o-oxy-benzoic acid (Märker, A. 124, 249). Silky needles (from alcohol). HNO, yields the nitro-compound C₆H₃(NO₂)O [150°].

Diphenylene oxide $C_{12}H_{0}O$ i.e. $C_{0}H_{4}>0$. [87°]. (283°) (Galewsky, A. 264, 188).

Formation.—1. By distilling Ph.PO, over lime, MgO, or PbO (Lesimple, A. 138, 375; Hoffmeister, Z. [2] 7, 24; A. 159, 211; Kreysler, B. 18, 1720).—2. By distilling phenol (2 pts.) with PbO (3 pts.) (Behr a. Dorp, B. 7, 398; Graebe, A. 174, 190).—3. By distilling Ca(OPh), (Niederhäusern, B. 15, 1120).-4. By the action of red-hot lime on di-phenylene-ketone oxide.— 5. One of the products of the action of HCl on mucic acid at 150°

Properties.—White plates (from accohol).

Converted by AscCl into CH₂.CO.C.H. O [81°], which yields an oxim [146°] and a phenyl-hydraxide [133°]. H₂SO₄ forms a deliquescent disciphonic soid, which yields BaC₁₂H₂S₂O₇ aq.

Picric soid compound C,H,OC,H,N,O, [24°]. Yellow crystals (Goldschmiedt a. Schmidt, M. 2, 14).

References.—Amido-, Brono-, Tevra-chloro-, Di-todo, Dinitro- Phenylene oxides.
o-PHENYLENE - OXY - BENZAMIDINE

 $C_{\bullet}H_{\bullet} < \stackrel{NH}{N} > C.C_{\bullet}H_{\bullet}.OH.$ [223°]. Formed by reducing salicyl-o-nitro-aniline with tin and HCl (Mensching, A. 210, 345). Needles.—B'HCl ad-B'H, SO, 4aq. Needles, sl. sol. Aq. o-PHENYLENE-PHENYL-DIAMINE. The

sulphonic acid which gives the barium salt sutphonic acta which gives the parium sate BaA', 2aq may be got from its amiliale [12:4] C_a[0.5,NHPh](NH₂).SO₂NHPh [157°] which is got by reduction of C_aH (NHPh)(NO₂).SO₂NHPh, and yields B'HCl [182°] (Fischer, B. 24, 3794).

p-Phenylene-phenyl-diamine
C_aH (NHPh).NH₂. Amido-diphenylamine. [67°]

and [75°]. (354°). - 1. By reduction of nitrodiphenylaraine (Nietzki a. Witt, B. 12, 1401). From p-nitreso-diphenylamine by boiling with alcoholic potash, by reduction with tin and HCl (Ikuta, A. 243, 279), or by treatment with phenyl-hydrazine in ether (O. Fischer, B. 21, 2615). 3. Together with azophenine, by heating p-nitroso-diphenylamine with aniline and aniline hydrochloride (O. Fischer a. Hepp, B. 20, 2480). 4. By reducing C₆H₄(NHPh)N₂C₆H₄SO₂Na (Hess a. Bernthsen, B. 18, 692).

Properties.—Plates or needles, sl. sol. water, v. sol. alcohol. Melts at 75° after crystallisation from ligroin. FeCl, added to a solution of its salts gives a red colour, turned green by excess. Yields quinone on oxidation.

Sult.—B'.H.SO. Plates.
Nitrosamine C,H.H.N.O. [c. 130°].
Acetyl derivative C,H.N.O. [158°].
Bensoyl derivative (Lellmann, B. 15,

Sulphonic acid.
[1:£2]C_aH_a(NHPh)(NH_a).SO₃H. Formed by reducing C_aH_a(NHPh)(NO_a).SO₃H (Fischer, B. 24, 3800). Yields Bah', aq and an anilide [171°], which gives B'HCl [215°].

m-Phenylene-di-phenyl-diamine C_oH₁(NHPh)₂. [95°]. Formed by heating resorcin (2 mols.) with aniline (2 mols.), CaCl₂ (8 mols.) and NnCl₂ (1 mol.) for 35 hours at 210° (Calm, B. 16, 2702). Flat needles, v. sol. ether. Oxidising agents give a green colour passing to bluish violet. Amyl nitrite and alcohol HCl form the p-nitroso-derivative C₁₈H₁₈N₂O, crystallising in brown-red prisms and yielding B"2HCl (Fischer a. Hepp, A. 255, 145). B"2HCl: needles decomposed by water.

Acetyl derivative C₄H₄(NPhAc)₂. [163°]. Benzoyl derivative C₄H₄(NPhBz)₂. [184"].

Nitrosamine C.H.(NPh.NO). Yellow needles, forming a violet solution in

H.SO., p.Phenylene-di-phenyl-diamine C_sH.(NHPh)_p. [132°] (Bandrowgki, M. 8, 475); [141°] (Limpricht, B. 22, 2910); [145°] (O. Fischer, B. 21, 2615); [152°] (Calm, B. 16, 2803). Formed by heating hydroquinone (5 pts.) with aniline (17 pts.), CaCl, (20 g.), and ZnCl, (5 g.) for 18 hours at 210°. Formed also by the action of phenyl-hydrazine on nitroso-diphenylamine in alcohol, and from the hydrochloride ! of amido-salicylic acid and aniline. Plates, v. sol. hot benzene. . HNO, added to its solution in H.SO, gives a blue liquid, changing to red.— B"2HCl: needles, decomposed by water.

Acetyl derivative C.H. (NPhAc). [192°]. Bensoul derivative C.H. (NPhBz).

Nitrosamine C18H14N4O2. [c. 120°].

Phenylene-di-phenyl-diamine C,H,(NH₂),NPh₂. Formed by reducing nitro-tri-phenyl-amine (Herz, B. 23, 2537). Crystalline. -B'HCl: silvery needles.

Acetyl derivative CoH4(NHAc).NPh2.

o-Phenylene-Phenyl-guanidine

C,H, NH>C:NPh. [1903]. (440°-450°).

Formed by heating phenylene o-diamine with di-phenyl-cyanamide at 215° (Keller, B 24, 2499). White needles (from benzese) or prisms (from alcohol). Phenyl-cyanate forms the compound NPh CO N2(CNPh) CH4. [266°]. B'HCl.—B'2H.PtCl.—B'H.SO4: long needles.

Mono-acetyl derivative. [160].

Di-benzoyl derivative. [171]. Needles. PHENYLENE - DI - PHENYL DIHYDRAZ. Rexahydride C6H16(NH.NHPh), Formed by reducing the di-phenyl-dihydrazide of quinone with sodium and alcohol (Baeyer a. Noyes, B. 22, 2175). Crystalline, sl. sol. alcohol.—B'H₂C₂O₁ aq.
m-PHENYLENE DI-PHENYL DIKETONE

C₆H₄(CO.C₆H₅)₂. Isophthalophenone. [95°] (M.); [100°] (A.). (above 360°). Formed from isophthalyl chloride, benzene, and AlCl₃ (Ador, Bl. [2] 33, 56; B. 13, 320; Münchmeyer, B. 19, 1848). Plates (from alcohol). Yields a monooxim [201°] (Nölting a. Kohn, B. 19, 146), a dioxim [70°-75°], and two di-nitro-derivatives [260°] and [c. 100°

p-Phenylene diphenyl diketone C_aH₄(CO.C_aH₄)₂. [160°]. Formed from terephthalic chloride, benzene, and AlCl₄ (M.). Yields a dioxim [235°].

Diphenylene di-phenyl diketone C₁₂H₈(CO.C₆H₅)₂. [218°]. Got from diphenyl, BzCl, and AlOi₃ (Wolf, B. 14, 2031). Crystals.

DIPHENYLENE-PHENYL-METHANE

 $C_{19}H_{14}$ i.e. $C_{C_8}H_{1}$ CHPh. [145.5°]. Formed by the action of P.O. or AlCl. on a mixture of benzene and diphenylene-carbinol; and also by heating CPh,Cl at 200° (Hemilian, B. 11, 202, 837; Bl. [2] 34, 325). Formed also in small quantity in the distillation of calcium benzoate or phthalate (Kekulé, B. 5, 910; Miller, B. 12, 1489). Needles, sl. sol. ether. Yields o-benzoylbenzoic acid on oxidation.

Reference.—DI-BROMO-DI-PHENYLENE-PHENYLE METHANE.

ν - m - PHENYLENE - DI - PHENYL - DI -METHYL-DI-PYRROLE DI. CARBOXYLIC-

FTHER C₂,H₂,O₄N₂ i.e.

CO₂Et.C:CMe

N.C₂H₁,N

CMe:C.CO₂Et

CPh;CH

Obtained by mixing together in acetic acid solution acotophenone-aceto-acetic ether (2 mols.) and m-phenylene diamine (1 mol.), and allowing the mixture to stand a long time (Paal a. Schneider, B. 19, 8161). Slender white

pyrrole di-carboxylic-ether C₄₀H₄₂O₄N₂ i.e. CO_Et.C:CMe N.C.H C.H C.H C.CO_Et HC:CPh N.C.H C.H C.H C.H.

[179]. Obtained by mixing together in acetic acid solution acetophenone-aceto-acetic, ether (2 mols.) and benzidine (1 mol.), and allowing the mixture to stand for a long time (P. a. S.). Hais like needles. Sol. alcohol and acetic acid,

v. sol. ether, chloroform, and petroleum-spirit.

p-PHENYLETE-TETRA-PHENYL-DI. PYRROLE DICARBOXYLIC ACID

CO₂H.C:CPh N.C₆H₄.N CPh:C.CQ₂H [above 300°]. Formed by saponification of its ether [250°] which is got from phenocyl-benzoylaccic ether and phenylene p diamine (Paal a. Braikoff, B. 22, 3095). Small grains.

m-PHENYLENE IN-PHENYL SULPHONE C₆H₁(SO₂Ph)₂. [191°]. Formed by heating benzene with P₂O₃ and benzene madisulphonic acid or di-phenyl sulphone m-sulphonic acid (Otto B. 19, 2421; 20, 185). Minute needles (from HOAc). Alcoholic potash at 170° forms O(C,H,SO,Ph), [70°] and C,H,SO,K.

Di-phenylene di-phenyl trisulphone $S\odot_2(C_aH_a,SO_2C_aH_a)_2$. [193°]. Formed from $SO_2(C_aH_a,SO_3H)_2$, benzene, and P_2O_a at 200° (Otto a. Rössing, B. 19, 3127).

PHENYLENE-DI-PHENYL-DI-THIO-DI-UREA C.H.(NH.CS.NHPh) alcohol (Lellman a. Würthner, A. 221, 28; 228, 200). The o- and p- compounds are decomposed by heat into di-phenyl-thio-ures and phenylene-thio-urea; the on- compound melts at 161°, and the o- isomeride at about 290°s. They are insol. ether.

m-PHENYLENE-DI-PHENYL-UREA C.H.(NH.CO.NHPh), Formed from m-phenylene-diamine and phenyl cyanate (Kühn, B. 18, 1478). Amorphous.

PHENYLENE-PROPENYL-DIAMINE

 $C_sH_s < NII > CEt.$ [169°]. (above 360°). Got by boiling o-phenylene-diamine with propionic acid (Wundt, B. 11, 829), and by reducing propionyl-o-nitro-aniline with tin and HOAc (Smith. Am. 6, 172). Plates (from water).—B'HCl.— B'HgCl₂.—B'₂H₂PtCl₈ 2aq.—B'₂H₂Cr₂O₇.

PHENYLENE-DI-PROPIONIC ACIDS C.H. (CH., CH., CO, H), Formed by heating C.H. (CH., CH. (CO, H), (Perkin a. Kipping, C. J. 53, 8, 32; B. 21, 27, 40). The o-acid [162°] forms Ag.A". The m-acid [147°] forms Me.A" [61°] and Et.A" (250° at 60 mm.). The p- acid [224°] forms Ag₂A" and Me₂A" [115°].

p.PHENYLENE-PROPYL-DIAMINE C.H.(NH.)(NIIPr). (281°). Got by reducing p-nitroso-propyl-aniline with SnCf. (Wacker, A. 243, 294). Plates.—B"2HCl. Plates, v. e. sol. Aq. o-PHENYLENE-PROPYLENE-DIAMINE

C_sH₄<NH>C₅H₆. [72°]. (28%). Formed by beating pyrocatechin with propyleng-diamine at 200° (Ris, B. 21, 382). Plates (from ligroin).

—B'_3HICl.—B'_2C_H_3N_O. Thin needles.

DIPHENYLENE-PYRAZINE. Dihydride C₁₆H₁₂N₂ i.e. C₆H₁,C.N.CH₂ Formed phenanthraquinone phenanthraquinone and ethylene-(Mason, B. 19, 112; 20, 267),—B',H.,PCl. ethylene-diamine (a)-PHENYLENE-BERIDYL-KETONE

C.H. CO.C.CH:CH. [141°]. Formed by dis-

tilling the dicarboxylic acid $C.H.O < \stackrel{().C(CO.H):CH}{C.N} > \stackrel{().C(CO.H):CH}{C.O.H} > [284°]$, which is formed by oxidising (a) styryl-(β)-naphthoquin-oline carboxylic acid (Doebber a. Peters, B. 23, 1241). Yields a picric acid compound [1972]. The dicarboxylic acid yields Ag₂A''. 1241).

[197°]. The dicarboxylic acid yields Ag,A".

(8) Phenylene-pyridyl-ketone

C₆H, CO,C. N. CH

CH, CO,C. N. manner from the corresponding dicarboxylic acid [264°] which is got by oxidising (a)-styryl-(a)-naphthoquinoline garboxylic acid with KMnO, Needles. Yields B'.H.PtCl, 2a_I. The dicarboxylic acid forms Ag,A' as a p.p. arboxylic acid forms Ag.A" as a pp.

PHENTLENE - QUINOLYLENE KETONE

OXIDE $C_{16}H_{9}NO_{2}$ i.e. $O< \stackrel{C_{6}H_{4}}{C_{9}H_{5}N}> CO$. Pheno-• quinoxanthone. [188°]. Formed by distilling p-oxy-quinoline with salicylic acid. (from alcohol).—B'HCl: needles. Needles

DIPHENYLENE QUINOXALINE C20H12N2 i.e. C₆H₁,C.N C₆H₄, [217°]. Got from phenylene-

o-diamine and phenanthraquinone (Hinsberg, A. V. sl. sol. alcohol. 237, 340),

DIPHENYLENE-STYRYL-OXAZOLE

C.H. C.N C.CH:CHPh. [172°]. Formed from phenanthraquinone, cinnamic aldehyde, and alcoholic NH₃ at 100° (Wadsworth, C. J. 57,

11). •Yellow needles.

p-PHENYLENE •DISULPHIDE C.H.S.. p-rheat least distinct of the solution of the solution of the solution (Lenckart, f. pr. [2] 41, 206). Chars without melting at 300°, incole ordinary solvents. Is reduced by former with could be solvents.

fusing with potash to dithiohydroquinone.

Diphenylene sulphide C.H. S. [97°]. (333°
î.V.). Formed by passing Ph₂S through a redhot tube (Stenhouse, A. 156, 332; Graebe, A.
174, 185). Needles, m. sol. alcohol. Yields on oxidation the sulphone C₁₂H₈SO₂ [230°].

Diphenylene - disulphide $C_sH_4 < S > C_sH_4$ [154°]. (366°). A product of the distillation of sodium benzene sulphonate (Stenhouse, Pr. 17, 62; A. 149, 252). Formed also by heating phenol with P.S. (Graebe, A. 174, 185; 179, 178), by heating benzene with S and AlCl., at 80° (Friedel a. Crafts, A. Ch. [6] 1, 550; 14, 439), and by heating C.H. (No. 1) N (Jacobson a. Elley R. 22, 210). Prisms (from CS.). Conc. Elley, B. 29, 910). Prisms (from CS₂). Conc. H₂SO₄ forms a purple solution. CrO₂ in HOAc gives the Sulphone C₁₂H₁₈S₂O₄ [325°] and the sulphoxide C₁₂H₁₈S₂O₄ [241°], sl. sol. cold benzene. Br forms C₁₂H₁₈S₂D₄ erystallising from CS₂ in a coll block witness

alcohol at 100° (Gabriel, B. 10, 184). Needles. v. e. sol. hot alcohol. Yields a nitro- compound

C.H.(NO.)(SCN), [150].
DIPHENYLENE SULPHONE v. DIPHENYL-ENE SULPHIDE.

DI-PHENYLENE SULPHONE KETONE

 $C_oH_i < SO_2 > C_oH_i$. [185°]. Formed by heating benzophenone with fuming H.SO, (Beckmann, B. 6, 1112; 8, 992), and by oxidising C.H. CO. C.H. (Graebe a. Schultess, A. 268,

Yellowish needles, v. sol. alcohol.
PHENYLENE DITHIOCARBAMIC ETHERS

o- compound [56°], m- compound [58°] (250°), and p- compound [130°] all crystallise in needles.

m-PHENYLENE - DI - THIO - DIGLYCOLLIC
ACID C.H.(SCH.,CO,H), [127°]. Formed from di-thio-resorein and ClCH,CO,H (Gabriel B. 12, 1639). Microcrystalline powder. Diphenylene-di-thic-di-glycollic koid

 $C_{12}H_8(S.CH_2.CO_2H)_2$. [252°]. Formed from $C_{12}H_8(SH)_2$. NaOHAq, and chloro-acetic acid (Gabriel, B. 13, 390).

o-PHENYLENE-THIO-URBA

 $C_sH_s{\stackrel{
m NH}{\sim}}CS$. [298°]. Formed by heating o-phenylene-diamine hydrochloride with am monium sulphocyanide and water at 180 (Lellmann, B. 15, 2146; A. 221, 9). Formed also from o-phenylene-diamine and CSCl. (Billeter a. Steiner, B. 20, 231). Plates (from dilute alcohol, sl. sol. water). The crystalline m-isomeride is got by heating m-phenylene-di amine with CS, and some alcohol at 150° (Gucci G. 17, 524). The p-isomeride melts at 271°. Phenylene-di-thio-di-ureas

C.H.(NH.CS.NH2)2. C_sH₄(NH.CS.NH₂)₂, m. [215°]. p. [220°] Formed by heating phenylene-diamine hydro chloride with ammonium sulphocyanide (Lell mann, A. 221, 11; B. 15, 28409. The p-compound is also formed from p-phenylene dithiocarbimide and alcoholic NH, (Billeter a. Steiner, B. 20, 230).

C.H.NH>CS. Diphenylene - thio - urea [238°]. Formed by heating di-op-amido-diphenyl with alcohol and CS2 (Reuland, C. J. 58, 167; B. 22, 3014)

o-PHENYLENE-TOLENYL-AMIDINE

 $C_eH_4Me.C \leqslant_N^{NH} \gt C_eH_4$. [268°]. Formed from o-phenylene-diamine and p-toluic chloride, and also by reduction of p-toluyl-o-nitro-aniline (Hübner, A. 210, 328; of. Brückner, A. 205, 115).

Hudner, A. 210, 528; cf. Bruckner, A. 200, 115).

Prisms (from alcohol).—B'H.Cl.—B',H.PtCl.—B'HNO,.—B',H.SO,: slender needles.

PHENYLENE-DI.-p.TOLYL.-n.-DIAMINE

C.,H.SN, i.e. C.,H.(NH.C.,H.Me).. [187°].

Formed by heating resorcin with p-toluidine,

ZnCl., and CaCl. (Hatschek a. Zega, J. pr. [2]

33, 218). Needles. Yields a di-nitrosamine

C. H. N.O. (c. 15°). a discatal derivative. CS, in small black prisms.

m-PHENYLENE SULPHOCYANIDE

C.H.(SCN), [54]. Formed by heating the lead salt of di-thio resoroin with ICy and C., H₁, N₁O₂ [c. 150°], a di-acetyl derivative C.H.,Ac.N., [1760], and a di-benzoyl derivative

Carlaber, [165], and a di-benzyl derivative Carlaber, [152].—B"2HCl; crystalline powder, decomposed by water.

Flemylene-di-o-tolyi-p-diamine [135]. (420°). Formed by heating hydroquinone with o-toluidine and CaClast 290° (Philip, J. pr. [2] 34, 65). Plates (from HOAc). Yields a di-benzylene [140°] Yields C. H. R. N. [235°]. [4] 64, 69. Plates from HOAC. Fields & dinitrosamine [140°]. Yields C₂₀H₁₆Bz₂N₂ [235°] and C₂₀H₁₆Ac₂N₂ [189°].—B"2HCl: needles. Phonylene-di-p-tolyl-p-diamine. [182°].

Formed by heating hydroquinone or phenyl-pamido-phenol with p-toluidine and ZnCl₂ at 220° (H. a. Z.); Calm, B. 16, 2810). Plates. Yields a di-nitrosamine [152°], a di-acetyl derivative [178°], and a di-benzoyl derivative [222°].—B"2HCl.

PHENYLENE-TOLYLENE-KETONE OXIDE

C.H. CO C.H.Me. Methyl-xanthone. [105°]. Formed by boiling p-tolyl salicylate (Graek a. Feer, B. 19, 2612; of. Scilert, J. pr $\P[2]$ 31, 479).

Isomeride $C_0H_4 \subset {}^{\circ}O_0$ $C_0H_0M_0$ $\begin{bmatrix} 3\\4 \end{bmatrix}$, $\begin{bmatrix} 16\\6 \end{bmatrix}$, $\begin{bmatrix} 16\\6 \end{bmatrix}$

Made by heating C₀H₃Me(OH)CO₂Ph [49°] (Weber, B. 25, 1745). Crystals (from algohol). o-PHENYLENE-p-TOLYL-GUANIDINE

C.H. C:N.C.H.Me. [209°]. Formed by heating o-phenylene-diamine with di-p-tolyl-cyanamide at 210° (Keller, B. 24, 2509). Tables. Yields a mono-acetyl derivative [152°], a dibenzoyl derivative [191°], and a nitrosamine $C_{14}H_{12}(NO)N_3$ [150°-160°]. Phenyl cyanate forms, C₆H₆N < CO N₂(C₆H₄):C:NC₆H₄Me [254°] crystallising from benzene in small needles. Di-p-tolyl-cyanamide at 210° forms the compound (NHC,H,)₂C:N₂(C₆H₄):C:N.C₆H₄Me [188°]. Salts.—B'HCl.—B'₂H₂PtCl₆.—B'₂H₂SO₄

DIPHENYLENE-TOLYL-METHANE C.OH16 i.e. C.H. CH.C.H.Me. [128°]. Formed by the action of P2Os on a mixture of diphenylenecarbinol and toluene, or of AlCl, on diphenylenecarbinyl chloride dissolved in toluene (Hemilian, B. 11, 203; Bl. [2] 34, 325). Silky needles.

PHENYLENE-DI-p-TOLYL-DI-METHYL-m-DIAMINE C₈H₄NMe.C₈H₄Me)₂. (c. 400°). Got by heating phenylene-di-p-tolyl-m-diamine with MeI and KOH at 150° (Hatschok a. Zega, J. pr. [2] 33, 223). Liquid smelling like geraniums.

The isomeric phenylene di-o-tolyl-di-methyl-p-diamine (385°-390°) and phenylene-di-p-tolyl-di-methyl-diamine [153°] may be prepared in like manner (Philip, J. pr. [2] 34, 57; H. a. Z.).

o-PHENYLENE-UREA C_eH₄<NH>CO.

[308°]. Formed by heating o-amido-phenyl-carbamic ether at 90° (Rudolph, B. 12, 1296), by Würthner, A. 228, 220), by heating its ethyl derivative with HCl (Sandmeyer, B. 19, 2654), and by the action of COCl2 in toluene on a solution of o-phenylene-diamine hydrochloride at 100° (Hartmann, B. 23, 1046). Leaflets, sl. sol. water.—B'HCl. Decomposed by water.

Ethyl derivative C.H. NH C.OEt. [160°]. Formed from o-phenylene-diamine and NH:C(OEt). Plates.

m-Phenylene-ures. Spore 500'l. Formed by similar methods (Michler a Zimmermann, B. 14, 2177; L. a. W.). Insoluble powder, ^Q
p. Phenylene-urea. [above 320°]. Got by

heating p-amido-di-phenyl-urea (L. a. W.). Isomeride. [130°]. Got by boiling an alcoholic solution of oxy-phenyl-thio-ures with HgO

(Bendix, B. 11, 2264). Tables, sol. water. Phenylene - di - ureas C₀H₄(NH.CO.NH₂)₂[290°]. · m- [above 300°]. Formed from phenylene-diamine hydrochloride and potassium cyanate in cold aqueous solutions (Warder, B. 8, 1180; Lellman, A. 221, 13; B. 16, 592). The p-compound can be heated to carbonisa tion without melting.

References .- AMIDO- and NITRO- PHENYLENE-

PHENYL-ENNOIC ACID.

G_aH₁₀C₃N₃Ph₂. [c. 38°]. (c. 293° at 15 mm.). Formed from decoic chloride, benzonitrile, and AlCl, (Krafft a. Koenig, B. 23, 2384).

PHENYL-ENNYL-THIO-UREAC, H. N. St.e. NHPh.CS.NHC, H19. [60°]. Formed from ennylthiocarbimide and aniline (Freund a. Schönfeld,

B. 24, 3359). Tables, v. sol. alcohol and ligroin.

PHENYL-ENNYL-UREA C₁₆H₁₂CN₂O i.e.

NHPh.CO.NHC₆H₁₈. [63°]. Formed from NHPh.CO.NHC₉H₁₉. [63°]. Formed from phenyl cyanate and aniline in alcohol (Freund a. Schönfeld, B. 24, 3358). Long prisms. s-DI-PHENYL-ETHANE CHH i.e.

CH_Ph.CH_Ph. Dibenzyl. Mol. w. 182. [53°]. (277°). S.V.S. 174·2 (Schiff, A. 223, 261). H.F. - 31,200. H.C.v. 1,828,300. H.C.p. 1,830,200 (Berthelot a. Vieille, Bl. [2] 47, 866).

Formation .- 1. By the action of Na on benzyl ehloride (Cannizzaro a. Rossi, At 121, 250; Fittig, A. 137, 257).—2. From ethylene chloride, benzene, and AlCl₂ (Silva, C. R. 89, 606; A. Ph. S. 18, 345).—3. From CHBr:CHBr, benzene, and AlCle (Anschütz, A. 235, 155). 4. From acctylene, benzene, and AlCl. Varet a. Vienne, Bl. [2] 47, 919).—5. By heating benzyl chloride with copper powder (Onurovitch, B. 17, 833).—6. A product of the action of Na on o-bromo-benzyl-bromide (Jackson a. White, Am. 2, 390). -- 7. By adding sodium (70 g.) to an alcoholic solution of phenyl-cinnamonitrile (Freund Remse, B. 23, 2859).

Properties.-Lung colourless needles, sol. alcohol, ether, and CS,

Reactions .- 1. Yields toluene and di-phenylethylene when passed through a red-hot tube (Otto, Z. [2] 6, 22; A. 154, 176; Barbier, C. R. 78, 1769).—2. Chlorine passed into fused s-diphenyl-ethane forms first CHPh:CHPh and then C.H.CI.CH:CH.CH.CH. (Rade, J. pr. [2] 19, 466). C.H.(C.CH.CH.C.H.(C. (Rade, J. pr. 12) 19, 400).
In presence of I, chlorine forms p-di-chloro-diphenyl-ethane in the cold. Exhaustive chlorization yields C.Cl. and C.Cl. (Merz & Weith, B.
16, 2877).—3. H.SO, forms a disulphonic acid
C.H.(SO,H), 5aq, which 'yields K.A'' 2aq,
BaA'' åaq, and PbA'' aq (Kade, B. 6, 958). A
tetra-sulphonic acid, C.H.(SO,H), 3aq, is also
formed. formed.

u-Di-phenyl-ethane CH₈.CHPh₂. (270°) (0.); (286°) (H.). Formation.-1. From CCl, CHPh, alcohol, and Na (Goldschmiedt, B. 6, 1501) .-- 2. From CH.Ph.CH.Br, benzene, and zinc-dust (Radzis-zewski, B. 7, 140).—8. From paraldehyde, benzene, and H.SO. (Bacyer, B. 7, 1190).—4. Together with ethyl-benzene and di-methyl-anthracene dihydride by heasing ethylidene chloride with benzene and AlCl. (Silva, Bl. [2] 41, 418; Anschütz, B. 17, 160).—5. By distilling its dicarboxylic acid (Haiss, B. 15, 1481).

Properties.—Oil, with blue fluorescence.

Solidities in a freezing mixture. Yields benzo-phenone on oxidation. Fuming HNO, added to pnenone on oxidation. Furning HNO, added to its solution in ROAc folius benzophenone, CPh_(OH), CH_2O.NO₂ [107°], di-phenyl-vinyl nitrite [87°], and a body [148°] which yields diphenyl-acetenitrile on reduction (Anschütz a.

Romig, A. 233, 329).

Tri-fhonyl-ethane CH.Ph.CHPh. (above 360°). Formed from CH.Cl.CHCl.OEt, benzene, and AlCl. (Waas, B. 15, 1128). Liquid, with violet fluorescence. Insol. cold alcohol.

s-Tetra-phenyl-ethane C₀₂H₂, i.e. CHPh₂-CHPh₂, Mol. w. 334. [210°]. S. (benzene) 14 at 80°. S. (95 p.c. alcohol) '8 on boil-

Formation.-1. By distilling benzoyl- and * succinyl- di-phenyl-carbinol and by distilling diphenyl-carbinol with succinic acid (Linnemann, 1. 133, 24).—2. By distilling benzophenone with zinc-dust (Staedel, B. 6, 1401).—3. By reducing benzpinacone CPh₂(OH).CPh₂(OII) with HI and P (Graebe, B. 8, 1055).—4. From di.phenyl-carbinol, glacial HOAc, conc. HClAq, and zinc (Zagumenny, A. 184, 176; BL [2] 34, 329).—5. By reducing (β)-benzpinacolin CPh₃.CO.C₆H₃ with HI and P (Zincke a. Thörner, B. 11, 67).— 6. By boiling (CHPh₂)₂S₂ with alcohol and copper powder (Engler, B. 11, 926).—7. By reducing CPh2:CPh2 (Friedel a. Balsohn, Bl. [2] 33, 388).—8. From CHIPI, Cl and Na (Engler).
9. By the action of benzene and AlCl, on CBr, CH, Br, on CHBr, CHBr, on CPhHBr, CHBr, on CPhBr. CPhBr., and on CHPhBr.CHPhBr, the yield in the last case being excellent (An-schütz, A. 225, 196).—10. By distilling CPh, HCl (Anschütz, A. 235, 220).

Properties .- Needles (by sublimation), sl. sol. alcohol. Crystallises from benzene with C.H. Yields a crystalline tetra-nitro-derivative, a crystalline tetra-sulphonic acid, which gives

Ba₂A¹ and C₂₅H₁₈(OH), [248°].

u-Tetra-phenyl-ethane CPh, CH, Ph. [140°]. Formed from CPh, K and benzyl chloride (Hanriot, C. R. 108, 1119).

References .- AMIDO-, BROMO-, BROMO-AMIDO-, DI-BROMO-DI-NITRO-, CHLORO-, PENTA-CHLORO-DI-MTRO-, NITRO-, and OXY-, PHENYL-ETHANES.

PHENYL-ETHANE DICARBOXYLIC ACID v. CARBOXY-PHENYL-PROPIONIC ACID and Prienyl-BUCCINIC ACID.

Phenyl-ethane tricarboxylic acid CHPh(CO,H).CH(CO,H),. [171°]. Got by sa ponifying its ether, which is made by the action ponitying its etner, which is made by the action of a-chloro-or a-bromo- phenyl-actic ether on sodium malonic ether (Spiegel, A. 219, 31; Alexander, A. 258, 71). Small tablets, v. sol. hot water. Decomposed on fusion into CO₂ and phenyl-succinic acid. Salts.—Ca₂A''', 10aq. Ga₂A''', 5aq. ppd. from aqueous solution by alcohol—Ag₂A'''; erystalline pp.

Ethyl ether Et.A". [46°]. (202° at 10 mm.). Needles (from dilute alcohol).

Di-phenyl-ethane o-carboxylic acid C_{la}H₁,O₂
i.e. C.H.,CH.,C.H.,CO.H. [131]. Formed
by the action of HI and P & 200° on isobenzylidene-phthalide, and on deoxybenzoin
carboxylic acid (Gabriel, B. 11, 1019; 18, 2440). Tablets (from dilute alcohol) .- AgA': pp.

Isomerides v. DI-PHENYL-PROPIONIC ACID. Di-phenyl-ethane di-o-carboxylic acid C₁₈H₁₁O₂• i.e. CO₂H.C₂H₄.CH₂.CH₂.C₄H₄.CO₂H. [186°] (H.) • [229°] (D.).

Formation.—1. By heating diphthalyl with HI and P (Grache, B. 8, 1055).—2. By the action of HI and phosphorus on the acid CO Co. CH. CH.CH.C.H.(CO.H. (Wislicenus, B. 17, 2181; Hasselbach, A. 243, 254), and on

diphthalylic acid (Dobreff, A. 239, 66).

Properties.—Small needles, v. sol. alcohol and dilute WOAc. KMnO, in alkaline solution forms diphthalylic acid [263°]. Distillation over soda-lime forms s-di-phenyl-ethylene.

Salts.—(NH₁),A" (dried at 100°),—CaA' (at *100°),—BaA".— Cu₂A"O.—Pb₂A"O.—Zn²A"O.—AgHA".

Methyl ether Me₂A'. [101°].

**Ethyl ether Et₂A''. [71°]. Converted by alcoholic NH, into the amic ether C₂H₄(C₆H₄,CO₂Et)(C₆H₄,CONH₂) [0. 67°].

Di-phenyl-ethane dicarboxylic acid C₄H₂CH₂CH₃CO₂H₃CO₂H₄ [1:2]. [154°]. (above 300°). Formed by heating the nitrile with conc. HCl at 220° (Eichelbaum, B. 21, 2082). Small prisms, sol. alcohol, insol. ether.

Nitrile C.H. CH. CH(CN).C.H. CN. [110°]. (above 300°). Formed from benzyl chloride and [1:2] C.H. (CN). CH. CN. Plates, insol.

water, alkalis, and acids. Amide. [221°]. Formed by the action of conc. H.SO, on the nitrile. Converted by conc. HC (S.G. 1.19) at 100° into the imide

 $C_uH_4<_{CO-NII}^{CH(C_1H_1)}>_{CO}[176^\circ]$ (above 300°).

Di-phenyl-ethane di-carboxylic acid CH₃CH(C₆H₁,CO₂H)₂. [275°]. Got by heating the tri-carboxylic acid (Haiss, B. 15, 1481). Long needles. May be sublimed.—CaA".

Isomeride v. DI-PHENYL-SUCCINIC ACID. Di-phenyl-ethane tri-carboxylic acid

CO.H.CMc(C₆H,CO₂H).. [255°]. Formed by oxidation of di-a-tolyl-propionic acid with KMnO₄ (Haïss, B. 15, 1479). Sol. alcohol and ether.—Ag₂HA'".—Ag₃A'".

Di-phenyl-ethae tri-carboxylic acid
C₁,H₁,O₂ i.e. CHPh(CO,H).CPh(CO,H).
A mide CHPh(CO,H).CPh(CO,H).CONH.

[190°]. Got from CHPh(CO,Et) CPh(CN).CO,Et [105°] which is got by heating a-chloro-phenylacetic ether with alcoholic KCy on a water-bath (Poppe, B. 23, 114).

Mono-nitrile CO.H.CHPh.CPh(CN).CO.H. The ethers Me.A" [101'] and Et. " (v. supra) are got from a [101] and Et. " (v. supra) are got from a-chloro-phenyl-acetic acid and KÖy in MeOH or EtOH. Conc. H.SO, converts Et. A" into CO Et. CHPh. CPh (CO. Et). CONH 1 [157] crystallising in aggregates of needles.

References.—Nitho- and Oxx- Di-Phen't-

PHENYL-ETHENYL-AMIDINE v. PHENYL-

PHENYL - ETHENYL - AMIDO - PHENYL -MERCAPTAN C., H, NS i.e.

 $C_*H_* <_S^N > C.CH_*Ph.$ Formed by heating phenyl-acetic chloride with o-amido-phenyl mercaptan (Hofmann, B. 13, 1234). Oil, sol. alcohol and ether. On fusion with potash it yields phenyl-acetic acid and amido-phenyl mercaptan B'HCl.—B',H.PtCl, 5aq: heedles, PHENYL-ETHENYL-AMIDOXIM C,H, N,O

i.e. C₆H₂CH₂C(NOH).NH₂. Phenyl-acetamid-oxim. [67°]. Got by heating phenyl-acetooverm. [07]. Got by heating phenyl-aceto-nitrile with a solution of hydroxylamine, in dilete alcohol (Knudson, B. 18, 1968, 2482). Thin prisms, v. sol. water. Converted by phenyl cyanate into C.H., C.H., C.(NH.CO.NHPh):NOH-[123°].—B'HOI. [155°]. White prisms. Acetyl derivative. [124°]. Plates.

Benzoyl derivative C,H,C(NOBz).NH2. [144]. Prisms, v. sol. alcohol.

[58°].

Ethyl other C,H,C(NOEt).NH₂.

Converted by potassium cyanate CH_Ph.C(NOEt).NH.CO.NHPh [148°]. into Bensyl ether. [55°]. Prisms.

Phenyl-ethenyl-amidoxim CH₃.C(NOH).NHPh. [121°]. Formed by heat-thioacetic anilide with hydroxylamine solution at 100° (Müller, B. 22, 2408; cf. Nordmann, B. 17, 2746). Satiny plates, v. sol. alcohol. FeCl, gives a violet colour, changing to olive green and, on heating, to red.—B'HCl: needles. -B'-H.PtCl.: vellow needles.

Bensoyl derivative C.H.,(NOBz).NHPh.
0°]. White needles (from dilute alcohol).
PHENYL-ETHENYL-AZOXIM V. AZOXIMS.
PHENYL-ETHENYL-DI-ETHYL-TRI-SUL-

PHONE CH. C(SO₂Et)₂(SO₂Ph). [109°]. Got by oxidation of CH₂.C(SPh)(SO₂Et)₂ (Laves, B. 25, 364). Needles, v. sol. alcohol.
TRI-PHENYL ETHENYL TRISULPHQNE

CH.,C(SO,Ph), [182]. Formed by the action of alcoholic NaOH, and MoI on CH(SO,Ph), Got also by oxidation of CH₂,C(SPh), by KMnO₄ (Laves, B. 25, 352). Needles, v. sol. CHCl₃.

DI-PHENYL-ETHENYL-DI-UREA

NHPh.CO.N:CMe.NH.CO.NHPh. [169°]. Formed by adding aqueous NaOH (2 mols.) to an aqueous solution of acetamidine hydrochloride (2 mols.) shaken with phenyl cyanate (1 mol.) (Pinner, B. 23, 2923). Needles, m. sol. alcohol. Converted by boiling dilute (50 p.c.) acetic acid Converted by boiling didde (so p.o., access doing into accety-phenyl-urea [189°].

PHENYL ETHER v. Dr.-PHENYL OXIDE.

C-PHENYL-ETHYL ALCOHOL C.H.10 i.e.

OH, CHPh.OH. Mol. w. 122. (203°). S.G. 1-013. Formed from CH, CHBr.C. H, by successive treatment with AgOAc and NaOH (Radziszewski, B. 7, 141; Berthelot, Z. 1868, 589). Got also by reducing acetophenone with sodiumamalgam (Emmerling a. Engler, B. 6, 1005). Yields an acetyl derivative C₈H₉OAc (217°-220°) which yields styrene on treatment with alcoholic potash.

Ethylether C.H.OEt. (186°). S.G. 22 931. Formed from CH, CHBr.C.H, and alcoholic NH, at 100° (Thorpe, Z. 1871, 131).

B-Phenyl - ethyl alcohol CH_Ph.CH_OH.

Bensyl-carbinol. (212°). S.G. 21 1034. Formed
by reducing phenyl-acetic aldehyde with sodiumforms the corresponding C2H_Ph_NH.CS NHPh

amalgam (Radziszewski, B. 9, 373). Oil. As.O at 150° converts it into an acetyl derivative C_sH₂OAc, (224°), S.G. 1·029. PHENYL-ETHYL-ALLOPHANIC ETHER

C₁₂H₁₆N₂O₃ i.e. C₈H₉.NH.CO.NH.CO₂Et. [106° Formed from phenyl-ethyl-urea and ClCO.Et (Neubert, B. 19, 1825). Needles (from water). PHENYL-ETHYL-ALLYL-GUANIDINE

PHENYL-ETHYL-ALLYL-GUANDINK CL2H., N. i.e. CN3,H_PhEt(C,H_). Formed by boiling ethyl-allyl-thio-urea with NHPh.HgCl and shoohol (Forster, A. 175, 41).—B'HgCl, aq. BHENYL-ETHYL-ALLYL-THIO-UBEA NH(C,H_).CS.NPhJ. [c. 26°]. Formed from allyl-thiocarbinide and ethyl-aniline (Gebhardt, B. 17, 180-180). B. 17, 3037). Colourless very soluble crystals. PHENYL-ETHYL-ω-AMIDO-ACETOPHEN-

ONE C16H17NO i.e. C6H3.CO.CH2.NPhEt. [95°]. Formed from ω -bromo-acetophenone and diethylaniline (Weller, B. 16, 26). Needles, PHENYL ETHYLAMIDO - ETHYL SUL-

PHONE C.H., SO., C.H., NHEL Formed from C.H.(SO, C.H.), and ethylamine at 85° (Otto, 7. pr. [2] 30, 337).—B'HCl. [130°]. Needles. PHENYL-ETHYL-AMIDO (a) NAPHTHO

QUINONE C₁₀H₃(NPhet)O₂ [155°]. Formed by heating (a)-naphthoquinone (2 pts.) with ethyl-aniline (3 pts.) and HOAc (5 pts.) (Els-bach, B. 15, 1810). Violet needles (from alcobach, B. 15, 1810). Violet needles (from alcohol,—19 HCl. [c. 230°]. Yellow needles, decomposed by water.

Phenyl - ethyl - amido - (β) - naphthoquinone. [165°]. Formed by heating (β)-naphthoquinone with ethyl-aniline and alcohol (Elsbach, B. 15, 691). Dark-red needles (from ether). Decomposed by boiling HClAq into ethyl-aniline and oxy-naphthoquinone.

PHENYL-ETHYL-AMIDO-PHENOL. Ethyl ether CushioNO i.e. NPhEt.CaH .OEt. (319"). Formed by heating phenyl-p-amido-phenol with alcoholic potash and Eti (Philip a. Calm, B. 17, 2434). Oil.

a.PHENYL-ETHYL-AMINE C.H., N i.e., CH., CHPh.NH., (187.5° i.V.). S. 4'166 at 20°. Formed by reducing the phenyl-hydrazide or the oxim of accophenone in alcoholic solution with HOAc and godium amalgam (Tatel, B. 19, 1999; 22, 1856; Kraft, B. 23, 2783). Formed also from acetophenone and sodium formate (Leuckart a. Janssen, B. 22, 1413). Liquid, miscible with alcohol and ether.—B'HCI, [158°]. -B'₂H₂PtCl_a.-B'₂H₂SO₄. [170°].-B'₂H₂CO₄. [238°]. Prisms, almost insol. alcohol.—B'H₂C₂O₄. Plates, m. sol. boiling alcohol.

Isomerides : - AMIDO-PHENYL-ETHANE ETHYL-ANILINE.

Di-phenyl-ethyl-amine C₁H₁N i.e. NPh_.Et,
Ethyl diphenylamine. (296°) (Girard, Bl. [2]
23, 3); (286°) (Lippmann a. Fleissner, M. 4,
727). Got by heating diphenylamine with
alcohol and HClAq. Oil.
Di-phenyl-ethyl-amine CHPh₂CH₂NH₂.

Formed by reducing di-phenyl-acetonitrile in alcohol with Na (Freund a. Immerwahr, B. 23, 2845). Oil.—B'HCl. [255°], V. sol. water. Di-phenyl-ethyl-amine CH.Ph.CHPh.NH. (310°) at 737 mm. Formed by heating deoxybenzoin (1 pt.) with ammonium dormate (2 pts.) at 225° (Leuckhart a. Janssen, B. 22, 1409). [170°]; while phenyl cyanate gives the com-

[170]; while pienyl cyanate gives an compound C.H.Ph.,NH.CO.NHPh [120].—B'H.Cl.,—B'H.NO,: needles.—B'H.SO,.

**Actyl derivative. [148°]. Needles.

**Benzoyl derivative. [178°]. Needles.

**Diphenyl-di-ethyl_mine NH(CH_CH_Ph),.

[336° at 603 mm.). Formed, together with NH_CH_CH_Ph and N(CH_CH_Ph), by the exting of give and HCHaq on paryl agenticities. action of zinc and HClAq on phenyl-acetonitrile (Spica, G. 9, 567). Formed also by distilling CH_Ph.CH_NH_Cl (Fileti a. Piccini, G. 9, 294). Liquid, sl. sol. water.—B'HCl. [270°]. Pearly scales.—B',H,PtCl, m. sol. water.
Tri-phenyl-ethyl-amine CPh,.CH,.NII,.

phenyl-acetonitrile (Spica, G. 9, 567). Oil.— b'HCl. [138°]. Needles, sl. sol. water. PHENYL-ETHYL-ARSINE v. vol. i. p. 321. PHENYLETHYL-TRIAZOLE CARBOXYLIC

ACID N.NPh C.CO.H. [145°]. saponifying its nitrile (Bladin, B. 18, 1548; 25, 176). Melts at 123° when crystallise from water or alcohol, but at 145° when crystallised from benzene.—B'HCl: plates.—CuA'₂ 33aq.— AgA': crystalline pp.

Methyl ether MeA'. [41°].

Ethyl ether EtA'. Oil.

Nitrile C₁₁H₁₀N₄. [38°]. Formed by the action of propionic anhydride on phenyl-hydrazine dicyanide. Converted by alcoholic NH, and H,S into C,N,PhEt.CS.NH, [150°] which crystallises in yellow prisms.

C,N,PhEt.CO.NH, Amide Formed from the nitrile, alcoholic potash, and

H.O., Small prisms, sl. sol. water.

De PHENYL-DI-ETHYL-DITRIAZYL

C. H. S. C. No. C. Formed by boiling phenyl-hydrazine dicyanide with propionic anhydride (Badin, B. 22, 3115). Groups of prisms.—B"2HCl: minute prisms, decomposed by water.

PHENYL ETHYL CARBAMIC CHLORIDE NPhEt.COCl. [c. 52°]. Formed from ethylaniline and CO₂ (Michler, B. 9, 396). Needles. PHENYL-ETHYL-SEMICARBAZIDE

C,H13N3O i.e. NHPh.CO.NH.NHEt. Formed from ethyl-hydrazine and phenyl cyanate (E. Fischer, A. 199, 295). Thin plates, m. sol. hot water. Yields a crystalline nitrosamine.

Phenyl-ethyl-semicarbazide

NHEt.CO.NH.NHPh. [151°]. Formed from phenyl-hydrazine and ethyl cyanate (Fischer, A. 190, 109). Monoclinic tables (from dilute alcohol) $a:b:c = .827:1:1\cdot146$; $\beta = 61^\circ$. Gives a bluish-black pp. with cold Fehling's solution, and Cu_iO on warming. Its nitrosamine crystal-lises from a etone in yellow needles [86:5°]. PHENYL ETHYL CARBONATE C, H, O, i.e.

C, H, O.CO. Et. (c. 234°) (P.). S.G. 2 1 1134 (P.) Formed from KOPh and ClCO, Et (Fatianoff, Z. 1808, 77). Formed also by the action of AlCl, on a mixture of phenol and ClCO, Et (Paw-laws): B. 17, 1902. lewski, B. 17, 1205). Liquid. By long heating at 300° it is split up into Ph₂CO₂ and Et₂CO₃. (Bender, B. 19, 2268).

Reference .- NITRO-PHENYL ETHYL CARBONATE. PHENYL-ETHYL-CYANAMIDE. by boiling phenyl-ethyl-hic-urea in benzene with Pbo (Weith, B. 8, 1650). Vitreous mass. DI.PHENYL-ETHYL-TRICTANIDE C,N,Ph.Et. V.D. 129. [67°]. (234° at 15 mm.). Formed by the action of AlCl. on a mixture of

henzonitrile and propionyl chloride at 70° (Krafft a. von Hausen, B. 22, 806). - B"H. PtCl.

PHENYL-ETHYLENE v. STYRENE. s.Di-fhenyl-ethylene C, H₁₃, i.e. CHPh:CHPh, Stilbene. Mol. w. 180. [124°]. (307° i.V.). H.C.v. 1,775,600. H.C.p. 1,777,300 (from dia-

Tri-phenyl-ethyl-amine CPh₂CH₂NNI₂ mond) (Berthelot a. Vieille, A. Ch. [10] 4, 50); [116°]. Formed by reducing CPh₂CN with zinc and HClAq (Elbs, B. 17, 700).—B'HCl. [247°].

Tri-phenyl-tri-ethyl-amine N(CH₂CH₂Ph)₃.

A product of the action of zine and HCl on e25, 616; Maercker, M. 136, 91; Anschütz, A. A product of the action of zine and HCl on e25, 616; Maercker, M. 136, 91; Anschütz, A. e25, 616; Maercker, 21. 130, 91; Auschutz, 2. 235, 296).—2. By distilling benzoic aldehyde with Na (Williams, Z. 1867, 432).—3. By heating benzoic aldehyde with phenyl-acetic acid and NaOAc at 250°; the yield being 55 p.c. (Michael, Am. 1, 313).—4. From s-di-phenylethane and Cl (Kade, J. pr. [2] 19, 465).—5. By heating benzylidene chloride with Na or with alcohol and zinc-dust (Limpricht, A. 139, 318; hipmann, J. 1877, 405).—6. By passing s-diphenyl-ethane through a red-hot tube (Otto a. Droher, A. 154, 177).—7. By heating benzoin with zinc-dust (Limpricht, A. 155, 80).—8. By passing teluene over heated PbO (Behr a. Dorp, B. 6, 754). - 9. By heating di-phenyl-acetylene with HI and P at 175° (Barbier, J. 1874, 421) .-10. By distilling lead phenyl-acetate with sulphur (Radziszewski, B. 6, 390). -11. Together with benzonitrile by the action of zinc-dust and HCl on C.H., CSNH. (Bamberger, B. 21, 55).-12. By heating di-phenyl-fumarate or di-phenyl-cinnamate (Anschütz, B. 18, 1945).—13. By heating CHPhBr.CHPhBr with alcoholic KSH in a sealed tube at 100° (Auwers, B. 24, 1779). 14. By heating thio-benzoic aldehyde at 190' (Baumann a. Klett, B. 24, 3308).

Properties .- Monoclinic plates, v. sol. ether, sl. sol. cold alcohol. Combines with N2O4 forming C₂H₂Ph₂N₂O₄ [c. 300°] crystallising in needles, sl. sol. hot alcohol (Gabriel, B. 18, 2438). Picryl chloride forms a combination $C_{14}H_{12}C_{4}H_{2}(NO_{2})_{3}Cl$ [71°] (Liebermann, B. 8, 2438).

Reactions.-1. Yields phenanthrene and toluene when passed through a red-hot tube (Graebe, B. 6, 126) .- 2. Reduced by HIAq at 150° to s-di-phenyl-ethano (Limpricht a. Schwanert, A. 145, 333).—3. Bromine added to an ethereal solution forms a product containing C₁H₂Br₂O₂ [121°] which gives rise to C₁H₂Br₂O₂ [150°] and C₁H₂Br₂O₂ [206°] and when dissolved in alcohol and reduced by solutions of the containing the contain when dissolved in alcohol and teather by soldium-amalgam yields C₁,H₁₀O₂, crystallising from alcohol in flat plates [172°], whence PCI, forms C₁,H₂ClO₂ [58°), C₁,H₂Cl₂O₂ [87°], and C₁,H₂Cl₂O₂ [190°] (Limpricht a. Schwanert, A. 153, 121).—4. Fuming HNO, added to an ethergal solution forms $C_{11}H_{11}N_{1}O_{2}$ [220°], which is converted by boiling alcohol into $C_{22}H_{22}N_{1}O_{1}$ [57°-73°] (Lorenz, B. 7, 1097; 8, 1050).

u-Di-phenyl-ethylene CH₂:CPh₂. (277°); (162° at 15 mm.). Formed by boiling CHPh₂:CH₂Cl with alcoholic potash (Hepp, B.7, 1409). Formed also by the action of benzene and AlCl. on

CH₂:CBr₂ and on CHBr:CBr₂ (Demole, B. 12, 2245; Anschütz, A. 235, 154. Liquid. Oxidised by CrO, to benzophenone. Combines with Br, forming CPh,Br,CH,Br, which readily gives off HBr, and forms bromo-di-phenyl-ethylene [40°] (c. 170° at 11 mm.).

Isomeride. [190°]. A product of the action of alcoholic potash on exo-chloro-di-phenylethane (Hepp, B. 7, 1412). Small plates (from ether). v. sl. sol. alcohol.

ether), v. st. soi. atconor.

Tetra-phenyl-ethylene C₂H₂₀ i.d. U.Ph₄.

Mol. w. 392. [221°]. (193° at 30 mm.).

Formation.—1. By heating CPh₂Cl₂ with finely-divided silver (Behr, B. 3, 751; 5, 277).—

The Lating herosphane with sing-dust nnely-divided silver [bein, B. 3, 101, 0, 21].—
2. By heating benzophenone with zinc-fust (Staedel, B. 6, 178, A. 194, 307).—3. By strongly heating chloro-di-phenyl-ethane (Engler a. Bethge, A. 174, 194, —4. From CPh.Br. by repeated distillation (Friedel a. Balsohn, Bl. [2] 33, 337).—5. A by-product in the prepara-tion of tri-phenyl-methane from benzene, chloroform, and AlCl, (Schwarz, B. 14, 1526).

Preparation.—1. By adding Br to di-phenyl-

methane and warming the resulting CIIPh, Br; the yield is 80 p.c. (Boissieu, Bl. [2] 49, (31).—

b. By heating di-phenyl-methane (20 g.) with sulphur (8 g.) for 9 hours to 250°, and finally for one hour to 290°, exhausting with ether, and recrystallising the residue from benzene; the

yield is 75 p.c. (Ziegler, B. 21, 780).

Properties.—White needles, v. sol. hot benzene and CS, v. sl. sol. other. Yields benzophenone (2 mols.) on oxidation (Anschütz, A. 235, 221). Yields a tetrasulphonic acid.

Isomeride C13H10? [244°]. Formed by heating (a)-benzpinacolin with soda-lime at 370° (Zincke a. Thörner, B. 11, 1397). Needles (from alcohol). Perhaps identical with the preceding. References .- DI-AMIDO-, BROMO-, DI-CHLORO-,

DI-IODO-, NITRO-, NITRO-AMIDO-, and OXY- PHENYL-RTHYLENE.

PHENYL-ETHYLENE-DIAMINE PHENYL-ETHYLENE-DIAMINE C₈H₁,N₂ i.e. C₈H₄NH.CH₂.CH₂.NH₂. (262° uncor.). Formed by boiling phenyl-amido-ethyl-phthalimide (got from bromo-ethyl-phthalimide and aniline) with conc. HClAq (Gabriel, B. 22, 2224). Liquid, miscible with water, forming an alkaline solution. Absorbs CO, from the air, forming a crystalline carbonate.—B"2HCl: small greenish needles, acid in reaction.— B"HCl. Neutral to methyl-orange. B"H_Br2. -Picrate [143°]. Flat yellow tables.

Di-acctyl derivative C₈H₁₀Ac,N₂. [116°]. Crystals, v. e. sol. Aq (Newman, B. 24, 2193). Di-benzoyl derivative. [143·5°]. Prisms.

Phenyl-di-ethylene-triamine C₁H₃N(C₂H₁NH₂)_r (above 300°). Formed by the action of boiling conc. HBr upon its di-phthalyl derivative NPh(C₂H₁N:C₂H₄O₂)_r [211°], which is a product of the action of aniline on bromo-ethyl-phthalimide at 100°-180° (G.). Thick ammoniacal liquid, miscible with water.

Absorbs CO₂ from the air.—B'H₂Br₂.—Pierate. [202²]. Needles (from alcohol).

**Oi-phenyl-ethylene-dismine C₁₄H₁₆N₂ i.e. C₁H₄(NHPh). [63²]. Prepared by heating ethylene bromide (1 mol.) with aniline (4 mols.); the yield being 80 p.c. of the theoretical (Morley, B. 12, 1794; cf. Hofmann, Pr. 10, 104; Gretillat, M. S. [3] 3, 383). Plates, v. sol. alcohol. Yields a di-nitrosamine C2H4(NPh.NO)2 [157°]. Reacts with benzoic amenyue forming the compound C.H. (NPh) .: CHPh [1870], while cuminic. salicylic, anisic, isobutyric, and heptoic aldeh les yield corresponding compounds [125°], [116°], [164], and [95°] respectively (Moos, B. 20, 732).—B"2HCl.—B"H.PLCl.—Mono-acetyl derivative. [128°]. Got

by heating the base with chloro-acetic acid and Na()Ac at 170° (Bischoff a. Nastvogel, B. 22, 1783).

Qi-acetyl derivative. [158°]. Crystals. Di-phenyl-ethylene-diamine C₁:H₁₆N₂ i.e. CHPh(NH.).CHPh(NH.). [121°]. Formed, together with benzoic aldehyde, by the action of boiling HClAq on C₂₈H₂₄N₃, which is a product of the action of New York, when the second of the section of New York, when the second of the section of New York, when the second of the section of New York, when the second of the section of New York, when the second of the section of New York, when the second of the section of New York New Y of the action of Na on amarine Grossmann, B. 22, 2299). Formed also by the action of cammonia on the hydrocyanide of benzoic alde-hyde (Limpricht a. Müller, A. 111, 142). Is per-haps identical with lophine. Plates (from hot water). Reacts with henzoic aldehyde forming CHPh:N.CHPh.CHPh.N.CHPh [164], m-nitrobenzoic aldehyde forming C₂₄H₂₂N₄O₂ [161°], with salicylic aldehyde forming C₂₄H₂₄N₂O₂ [205°], and with cuminol forming a compound [168° B"2HCl. White needles (from hot water).-B"H_PtCl, : dark-yellow crystals

Di-acetyl derivative. [above 350°]. Phthalyl derivative C_a I.: C_aO_a : N_aH_a : C_aH_a Ph_a. [213°]. Minute crys-

Di-phenyl-di-ethylene-diamine C18H18N2 i.c. NPh C.H. NPh. Diphenylpiperasine. Diphenylpyrazine hexahydride. [163°]. (c. 300°). Prepared by heating ethylene bromide (1 pt.) with aniline (1 pt.) and NaOAc, and by the action of ethylene bromide on di-phonyl-ethylene-diamine at 120° (Morley, B. 12, 1795; Bischoff, annue at 120 (arriey, B. 12, 1735; Bischoll, B. 22, 1777; cf. Hofmann, Pr. 9, 277; 10, 104; Lellmann a. Schleich, B. 22, 1387; Bischoff, B. 22, 1778). Formed also by heating pyrazine hexahydride (1 pt.) with bromo-benzene (11 pts.) at 270° (Schmidtea. Wichmanf, B. 24, 3239). Needles, sol. alcohol and ether . Its solutions are neutral to litmus. Yields a crystalline di-nitroso-derivative which may be reduced by tin and HCl

to C₆H₃(NH₂)N<CH₂.CH₂NC₆H₃NH₂, which, when diazotised and combined with naphthylamine sulphonic acid, yields a colouring matter which dyes cotton.—B"2HCl.—B"H₂PtCl₆.

Methyl-iodile B'MeI. Crystalline. Yields B'2Me2PtČl6.

Ethylo-iodide BEil. [100°]. B',Et,PtCl.

References .- NITRO- and OXY- DI-PHEN TO-ETHYLENE-DIAMINE.

• DLPHENYL . ETHYLENE . DI . BENZYL . DI . AMINE CHPh(NICH,Ph). CHPh(NHCH,Ph), [153°]. Formed by reducing the compound CHPh(N:CHPh). CHPh(N:CHPh) [163°], which is itself got by reducing amarine with Na (Grossmann, B. 22, 2301). White meelles.

DI PHENYL - ETHYLENE - DICARBAMIC

DI PHENYL BIR ACID C4H (NPh.CO.H).

Ethyl ether Et,A". [88°]. N

Chloride C4H (NPh.COCI). 188°1. Needles. [183°] Formed from di-phenyl-ethylene-diamine and COCl. (Hanssen, B. 20, 781). Prisms.

DI-PHENYL-ETHYLENE DI-o-CARBOXY-C,H,(CO,H).CH:CH.C,H,CO,H. ACID LIG [264°]. Formed by heating for four hours at 215° CO CoH CH.CH, CoH, COH (2 pts.) with KCy (5 pts.) (Hasselbach, A. 243, 258). Small needles (from dilute HÖAo). Changes on heating into the parent acid [196°]. Reduced by conc. HIAq to C.H. (C.H., CO.H), [185°].—Ag.A". Floculent pp.

Ethyl ether Et.A". [80°]. Needles. Isomeride v. DI-PHENYL-MALEÏC ACID. References.—Nitro- and Oxy- Di-Phenyl-ethylene carboxylic acids.

DI - PHENYL - ETHYLENE - DI - ETHYL -DIAMINE C₁₈H₂₄N₂ i.e. C₂H₄(NPhEt)₂. [70"].
Formed from di-phenyl-ethylene-diamine and

EtI (Hofmann, Pr. 10, 104).—B"2HI.— B"H,PtCl, needles.

PHENYLETHYLENE-GLYCOL v. DI-0xx-

ETHYL-BENZENE. DI-PHENYL-ETHYLENE-DI-HYDRAZINE C14H18N4 i.t. C2H4(NPh.NH2)2. [90°]. Formed from sodium phenyl-hydrazine and ethylene bromide in benzene (Burchard a. Michaelis, B. 21, 3202; A. 254, 116). Prisms or olates. Aldehyde forms C.H.(NPh.N:CHMc). [82°]. Benzoic aldehyde forms an analogous body [193°]. Acetone and acetophenone form analogous compounds [72°] and [118°]. Phenyl-thiocarbinade forms NH,NPh.C.H,NPh.NH.CS.NHPh [164°] forms NH_NFI...TI, MALCS.NIIPh)₂ [194°]. Yields a crystalline nitroso derivative [160°]. SOCI₂ forms C₂H₄(NPh.N:SO). [123°] (Michaelis a. Ruhl, A. 170, 122).—B"H.Cl., [212°]. Necdles, sl. sol. HClAq.—B"H₂SO₄—B"2HNO₄ [173°].— SOCl₂

B"H₂C₂O₄ [183²].

Acetyl derivative C₁₁H₁₆Ac₂N₂ [222²].

Succinyl derivative C₁₁H₁₆N₂:C₁H₄O₂.

[c. 126°].

Succinoxyl derivative .

Succinoxyl derivative .

C₂H₁(NPh.NH.CO.C₂H₁.CO.H)₂. [203°].

Oxalyt derivative C₁₄H₁₆N₂:C₂O₂.

Di-phenyl-di-ethylene-dihydrazine

(C₂H₄),(N₂HPh)₂. [178°]. Got by heating phenyl-hydrazine with C₂H₄Br₂ and alcohol (Marckwald, C. C. 1888, 1410). DI-PHENYL ETHYLENE DIKETONE

C.H., CO.CH., CH., CO.C., H., Diphenacyl. Succinophenone. [134°] (A.); [140°] (C.); [142°-145°] (P.). Formation.—1. Together with the isomeric CH. CO by the action of succinyl chloride and AlCl₃ on benzene (Auger, A. Ch. [6] 22, 312 : Claus. B. 20, 1374) .- 2. From acctophenone by treatment with fuming HNO, and reduction of the resulting $Q_{10}H_{10}N_{10}O_{10}$ by zinc-dust and HOAc (Hollemann, B. 20, 3301).—3. By the action of KOHAq on di-benzoyl-propionic acid suspended in alcohol (Paal, B. 21, 3056).

Properties. - Needles, v. sol. ether.

Oxim Q.H. (CPh:NOH). [2014].

Phenyl. hydrazide C.H. (CPh:N.HPh).

O']. Needles, v. sol. ether.

DI. PHENYL ETHYLENE DIKETONE

CARBOXYLIC ACID v. PHENACYL-BENZOYL-ACETIC ETHER.

Di-phenyl-ethylene diketone di-o-carboxylic cid Ci.H.O. i.e. C.H.(CO.O.H.,CO.H). [172°].

Obtained by boiling di-phthalyl-ethane with

alkalis (Gabriel a. Michael, B. 10, 1561, 2199; Roser, B. 17, 2622; 18, 803, 8115; Baumann, B. 20, 1486). Prisms (from water), v. sol. alcohol. Reconverted by conc. H₂SO₄ into di-phtralyl ethane C.H₂(C₄O₄C₄H₄)₄. A boiling alcoholic solution of phenyl-hydragine forms C₃₀H₂₂N₄O₂ [237°]. Hydroxylamine at 100° gives rise to $C_2H_4(C < C_0H_4 > CO)_2$ [270°] (Baumann, B. 20,

1492).—Ag₂A": small plates, sl. sol. hot water.
(a).An hydride C₁, H₁₂O₂. [230°]. Got by heating the acid alone, or together with diphthalyl-ethane, by heating it for a short diphthalyl-ethane, by nearing time with HCl. Needles (from alcohol).

by more from great the acid with HCl, and also, together with the (a)-isomeride, by heating the acid by itself. Prisms (from alcohol). Both anhydrides are reconverted into the acid by boiling alkalis, and into di-phthalylethane by elimination of H.O.

Isomeride v. DI-BENZOYL-SUCCINIC ACID.

PHENYL ETHYLENE OXIDE CHPh>O. (260° at 50 mm.). Formed by heating di-oxyetts:1-lienzene with dilute H₂SO₁ (Breuer a. Zincke, B. 11, 1402). Oil. Converted by PBr, into CHPhBr.CH.Br.

Tetra-phenyl-ethylene oxide v. Benzpinaco-

PHENYL-ETHYLENE SULPHIDE

CHPh>s. S.G. 16 1.099. Formed from PhCHBr.CH,Br by successive treatment with alcoholic KSHAq (Spring a. Marsenille, Bl. [3] 7, 13). Oil with strong smell, sol. alcohol-ether. Oxidised by CrO, to benzoic acid.

CHPh>s. Di-phenyl-ethylene sulphide [169°]. A product of the distillation of benzyl sulphide (Barbier, J. 1876, 421). Needles.

Di-phenyl-ethylene disulphide C₂H₄(SPh)₂.

J. Formed from NaSPh and C₂H₄Br₂

(Ewerlöf, B. 4, 716). Needles, insol. water. DI-PHENYL-ETHYLENE DISULPHONE

C₂H₄(SO₂C₆H₅)₂. [180°]. Formation.—1. By oxidation of C₂H₄(SPh)₂ (Ewerlöf, B. 4, 717).—2. By boiling sodium benzene sulphinate (100 pts.) with C.H.Br. (58 pts.) in alcohol (Otto, B. 13, 1279; J. pr. [2] 30, 174).

3. By adding CH., CCl., CO., Na (1 mol.) to C., H., SO., Na (2 mols.) in weak alcoholic solution, kept neutral by Na CO₂ (Otto, J. pr. [2] 40, 531). 4. By heating CH₂CCl₃ with C₈H₅.SO₂Na at 160° (Otto, B. 21, 1691).

Properties .- Triclinic needles or plates, sl. sol. water, m. sol. alcohol, v. sol. HOAc.

Reactions.—1. Sodium-amalgam reduces it to alcohol and C.H. SO.Na, which is finally reduced to C.H.SNa.-2. Chlorine in diffused daylight forms $C_2H_1Cl_2$ and benzene sulphonic chloride. In sunlight the products are $C_2H_1Cl_2$, SO₂Cl₂, and chlorinated benzenes.—3. Boiling aqueous KOH splits it up into C,H,SO,K and C.H. SO, C.H. OII. Conc. KOHAq forms's C₀,H₀,SO₂C₂H₁,Cil. Conc. K(HAq forms a compound [88°] crystallising from alcohol.—4. Aqueous NH, forms C₀H₀,SO.ONH, and (C,H₀,SO₂CH₂CH),NH [78°] which yields B'HCl [193°], B'₂H₂PtCl₁, a nitrate [190°], and the derivatives (C₀H₁,SO₂CH₂CH₁)₂NMc and (C₀H₀,SO₂CH₂CH₁)₂NMcHCl [221°].—5. Aqueous

C.H.SO,NH,Et ethulamine forms and C_eH₄,SO₂C₂H₄NHEt, an oil which yields B'HCl [180°].—6. Alcoholic KCy forms C_eH₃SO₂K and C.H.(CN)...

PHENYL-ETHYLENE-THIO-UREA

CS<NPh>C2H. [155°]. Formed from phenylethylene-diamine and CS, (Newman, B. 24, 2191). White plates, v. sol. alcohol.

Di-phenyl-ethylene-ψ-thio-urea

 $C_{H} < \frac{NPh}{S} > C_{S}NPh.$ [136°]. (above 4800°).

Formed by heating di-phenyl-thio-urea with ethylene bromide (Will, B. 14, 1490; 15, 343). Plates (from alcohol), KClO, and HClAq form C,H,N,SO, [187°] (Andreasch, M. 4, 134).—B'H,SO; thick prisms, v. sol. water.

Di-phenyl-ethylene-di-thio-di-urea

[193°]. C16H16N4S2 i.e. C2H4(NH.CS.NHPh)2. Formed from C₂H₄(NH₂)₂ and phenyl-thio-carbimide in alcohol (Lellmann a. Würfiner, A. 228, 234). White scales, insol. alcohol, sl. sol. HOAc. Decomposed by heat, giving di-phenyl-thio-urea and a crystalline body [164°]

PHENYL-ETHYLENE-UREA

C₂H₄<NPh>CO. [161°]. Formed from phenylethylene-diamine hydrochloride and potassium cyanate, NH, being given off (Newman, B. 24, 2192). Plates, v. sol. alcohol, insol. cold water.

Di - phenyl - ethylene - urea CH...NPh CO.

[209°]. Formed by the action of COCi, in benz. ene on C2H, (NHPh)2; an intermediate body being C₃₁H₂₈N₄Cl₂O₃ (Michler a. Keller, B. 14, 2183; Hanssen, B. 20, 784). Plates.

PHENYLETHYL-ETHYL-PYRIDINE

 $\mathbf{C_{1b}H_1,N} \text{ i.e. } \mathbf{N} \leqslant \begin{matrix} \mathbf{C(CH_2.CH_2Ph).CH} \\ \mathbf{CH:CEt} \end{matrix} \qquad \qquad \mathbf{CH}. \quad (316^{\circ} \text{ cor.}). \end{matrix}$ S.G. 9 1.016. Formed by reducing styryl-ethylpyridine with HIAq at 165° (Plath, B. 21, 3003; 22, 1057). Oil, v. sl. sol. water, v. sol. alcohol 22, 1037), OH, V. S. SOI, WALET, V. S. SOI, ARCHOM.

[1282] whence AgOAc forms C, H, (OAc), N

(815°-820°). — B', H, l'tCl. [168°]. Vellow

meddles. — B'HHgCl. [136°]. Needles. —

B'HAUCl. aq: crystalline mass.

Hexahydfide C13H28N. (314°). S.G. 9663. Got by reducing the preceding body in alcohol with Na. Oil, sl. sol. water, miscible

with alcohol and ether.

PHENYL-ETHYL-FURFURANE

C.H., CH., CH., C,H.,O. (241°). A product of the action of Na on an alcoholic solution of C.H.O.CH:CPh.CN, which is formed by condensation of furfuraldehyde with phenyl-acetonitrile (Freund a. Immerwahr, B. 23, 2848). smelling like CH. Ph2.

DI-PHENYL-ETHYL-GUANIDINE

C₁₈H₁₁N₂ i.e. NHEt.C(NPh).NHPh. Got from phenyl-ethyl-cyanamide and aniline at 100° (Weith, B. 8, 1531). Crystalline.—B'2H2PtCls.

*PHENYL-ETHYL-HYDANTOIN C₁₁H₁₂N₂O₂
i.e. CHPh NH.CO . [94°]. Formed from phenyl-hydantoin, alcoholic KOH, and EtI (Pinner, B. 21, 2325). Prisms, v. sol. alcohol, al. sol. cold water. Decomposed by baryta into ethylamine and phenyl-amido-acetic acid.

Phonyl-ethyl-\psi-hydantoin

CHPh CO.NEt Separates from a dijute alkaline solution of the preceding isomeride on standing. Slender needles, insol. water, nearly insol. alcohol. Decomposed by heating with baryta-water into NH, NH,Et, and a-oxyphenyl-acetic acid.

u-PHENYL-ETHYL-HYDRAZINE C.H.,2N. i.e. NPhEtaNH, (230°). Formed by reducing the nitrosamine of ethyl-aniline with zinc-dust, HOAc, and alcohol (Fischer, B. 8, 1642; A. 199, 325; Philips, B. 26, 2485). Formed also from EtBr and NPhN&NH, in benzene (Michaelis a. Philips, A. 252, 270). Oil. Reduces Febling's colution on manufacturing Ovidious two Hoads. solution on warming. Oxidised by HgO to solution on warming. Oxidised by HgO to diphenyl-di-ethyl-tetrazono NPhEt.N:N.NPhEt [108]. SOCI, forms oily NPhEt.N:SO (Michaelis, B. 22, 223).—B'HCl. Plates.

**Acetyl derivative NEIPh.NHAC. [80°].

Ebby lo-bromide NH, NPhEt, Br. Trimetric prisms (from alcohol); a:b:c = 822:1: 827. V. e. sol. water, insol. ether. Decomposes at 193°. Insol. KOHAq. Converted by moist Ag₂O into a caustic hydroxide. Yields also (NH₂APhEt₂)₃H₂Fe₂Cy₁₂2aq (Fischer, A. 190,

Ethylo-chloride NH, NPhEt.Cl. [198°]. Needles, v. e. sol. water. B' Et.PtCl.

Ethylo-iodide NH. NPhEt,I. s-Phenyl-ethyl-hydrazine NHPh.NHEt. Formed, together with the preceding isomeride, by heating phenyl-hydrazine with EtBr. The crude product is dissolved in water mixed with NaOHAq, and the ppd. oil extracted with ether. The ethereal solution is freed from phenylhydrazine by HCl and the filtrate oxidised by HgO. On addition of HCl it deposits di-phenyldi-ethyl-tetrazone, and the mother-liquor yields by steam-distillation oily C.H.N:NEt 4175°... 185°). The NRh:NEt is then reduced by sodium-

amalgam (Ehrhardt a. Fischer, B. 11, 613).

Properties.—Oil, sol. alcohol and ether.

Readily reduces Mehling's solution and HgQ. Zinc-dust and HOAc yield aniline and ethyl-

amine. -B'H.C.O.: needles, v. sol. hot water.
DI-PHENYL-ETHYLIDENE DIAMINE

Ethylidene-di-aniline, vol. ii. p. 496. DI - PHENYL - ETHYLIDENE - DI - ETHYL-DIAMINE C₁₈H₂₁N₂i.c. CHMe(NPhEt)₂. Formed from ethyl-aniline and aldehyde (Schiff, A. 140, 95; cf. Schultz, B. 16, 2601). Thick liquid .-

B',H,PtCl. PHENYL-ETHYLIDENE DI-ETHYL DI-SULPHONE CH3.CPh(SO2Et)2. [101°]. Formed from benzylidene di-ethyl di-sulphone, Mel, and EtONa (Fromm, A. 253, 154). Needles.

PHENYL-ETHYLIDENE-HYDRAZINE CH, CPh:N.NH2. (255°). Formed from acetophenone and hydrazine hydrate (Curtius, J. pr.

phenome and nyarane nyarane counts, J. Pr. [2] 44, 540). Liquid. Yields CH., CPh:N.N:CHPh [59°] and N., CPh.CH.), [121°].

DI-PHENYL ETHYLIDENE DISULPHONE CH., CH(SO,Ph)., [102°). Got by oxidising CH., CH(SPh)., CO,Ph with dilute (1 p.c.) KMnO. (Escales a. Baumann, B. 19, 2915). Needles or thin lamella, insolv water, acids, and alkalis, sl. sol. alcohol and ether.

Not attacked by alcoholic potash at 140°. PHENYL - ETHYLIDENE - DI - THIO - DI CH. CPh(S.CH,.CO.). GLYCOLLIC ACID

[186°]. Got by the action of ZnUl, on a mixture of acetophenone and thioglycollic acid (Bongastz, B. 21, 483). Needles, sol. hot water. CHCl., and HOAc.

Dilactone C. H. OCO.

PHENYL-ETHYL-IMESATIN v. Di-phenyl-

di-ethyl-diamide of Isatyn.

PHENYL ETHYL KETONE C, H, O i.e. C.H..CO.C.H. Propiophenone. [210]. cor.) (M. a. G.). V.D. 464 (obs.). S.G. 2 1.009

(W.). Formation .- 1. By distilling a mixture of calcium benzoate and propionate (Barry, B 6, 1006). 2. From BACI and Calct. (Freund, A. 118, 20; Kalle, A. 119, 166). 3. By the action of Na on a mixture of BzCl and Etl (Bechi, B. 12, 463). - 4. By the action of propionyl chloride Green, B. 17, 3018; Pampel a. Schmidt, B. 19, 62896).—5. By the decomposition of propylene phenyl-ethyl-ketate by HI or H.SO, (Morley a. Green).—6. By oxidising CHPhEt.OH (Wagner, J. R. 16, 325).—7. From benzoyl cyanide and J. R. 16, 325).—7. From benzoyl eyanide and which is got from phthalyl-malonic ether and ZnEt, either directly or by oxidising the product NaOEt (Wislicents, A. 242, 58). Oil.—Ag,A'v. (Frankland a. Louis, C. J. 37, 745).—8. From PHENYLETHYL METHYL KETONE v.

phenylallylene (Körner, B. 21, 277).

Properties. Tables. Does not combin with NaHSQ.. Yields benzoic acid on oxidation. Reduced by sodium-amalgam to CHPhEt.OH (211°).

Oxim CPhEt:NOH. Oil.

Phenyl hydrazide. Oil.

Phenyl ethyl diketone C.H., CO.CO.C.H., Propionyl-benzoyl. (239°). Got by distilling its mono-oxim (obtained from ethyl benzoylacetic other) with dilute H.SO, (Müller a. Pechmann, B. 22, 2131). Pungent liquid, volatile with steam, m. sol. water.

Reference. - NITRO- and OXY- PHENYL ETHYL KETONE.

PHENYL ETHYL KETONE DIBROMIDE v. DI-BROMO-CUMENE.

PHENYLETHYL KETONE o-CARBOXYLIC ACID C.H., CO.C., II., CO.H. Propionyl-benzoic zeid. [92°]. Formed by boiling phthalyl-propionic acid with KUHAq (Gabriel, B. 11, 1014; 10, 840). Needles (From. Elitherhelm). 19, 840). Needles (from dilute alcohol) .-- AgA'.

Anhydride C, H, CCCHMe) >0.

Formed by heating phthalic anhydride with succinic acid and NaOAc (G.). Formed also by listilling the anhydride of the dicarboxvlic acid Roser, B. 18, 3117). Plates (from water). Com-

bines with N₂O₄ forming C₁₆H₈N₂O₆ [90°].

A mide C₆H₄(CO.NH₂).CO.C₂H₃. Formed from the anhydride and alcoholic NII. Isomerides v. Benzoyl-propionic acid, vol. i.

o. (87.

Phenyl ethyl ketone dicarboxylic acid J.H.,CO.CH, CH(CO.H), β-Benzoyl-isosuccinio wid. [180°]. Obtained by saponifying its ether which is formed from w-bromo-acetophenone and sodium malonic ether (Bischoff, B. 16, 1044; 19, 99; Kues a. Paal, B. 18, 3321). Needles, v. sol. alcohol and ether. Yields β penzoyl-propionic acid when heated. - A . A": needles. - Et. A": oil.

Phenyl hydrazide J.H..C(N.HPh).CH.CH(CO.H). Phonyl ethyl ketone dicarboxylic acid

C.H.CH.CH.C.H.Et. [90°]. Formed by boilC.H.CO.H.CO.CH.CO.H. [137°]. Formed ing CH.Ph.CH(OH).C.H.Et[1:4] with dilute
by bolling its dilactone with water or aqueous H.SO. (Söllscher, B. 15, 1681). Plates.

[1860]. Got by the action of ZnCl, on a mix- | alkalis. Small six-sided prisms, re-converted by

product of the action of phthalic anhydride on succinic acid and NaOAc. at 2503 (Roser, B. 17. 2770; 18, 804, 3115). Needles, sl. sol. cold water. At 260° it gives off CO, and changes to C.H. COO C:CHMe. HIAq and P at 190° reduce it to C₀H₁(CO,H),CH₂CH₂CH₂CO₂H, Cold NH₃Aq forms CO,NH>CCH,CH₂CO₂H |225°]. Boiling alcoholic NII, forms C, II, NO, [c. 205°]. Sodiumamagam reduces it to phthalyl-propiotic acid $C_{11}H_{12}O_{4}$. Phenyl bydrazine forms $C_{11}H_{11}N_{2}O_{4}$ [210°] which gives CaA'₂ aq.

Isomeride v. Benzöyl-succinic Aold.

Phenyl ethyl ketone tetracarboxylic acid C,H,CO,H),CO.C(CO,H),CH,CO,H. Formed by the action of chloro-acctic ether on C. H. NaO.

BENZYL ACETONE. Diphenylethyl methyl ketone CH, CPh, CO.CH, [415]. (311° i.V.). A product of the action of zine and HCl on an alcoholic solution of acctophenone (Zincke a. Thörner, B. 11, 1989). Prisms (from alcohol).

PHENYLETHYL-METHYL-PYRIDINE $C_{11}H_{13}N$ i.e. $C_{1}H_{1}Ph.C_{1}H_{3}MeN$. (290°-295°). S.G. (10283. Formed by reducing styrylmethyl-pyridine with HIAq at 160° (Bachér, B. 21, 3076). Oil, volatile with steam. B',H,PtCl, [168°]. -B'HH₅Cl, aq. [95°]. Silky needles. -B'C_aH,N,O₂. [156°]. Yellow needles Hexahydride C₁₁H₄N. (c. 288°). S.G. ⁹

19775. Got by reducing styryl-methyl-pyridine

in alcohol with Na. Liquid, v. sl. sol. water. **PHENYL-ETHYL-**(β)-**NAPHIHOTRIAZINE** DIH TORIDE C10 H11 N3 i.e. C10 H1 N:CHEt [219°]. Formed by adding propionic aldehyde to benzene azo-(B)-naphthylamine in alcohol (Goldschmidt a. Poltzer, B. 21, 1006). needles, v. sol. alcohol. B'HCl. [258°].—
B'₂H.PtCl. Small yellow crystals.
PHENYL-ETHYL-OXAMIDE C_{1n}H₁₂N₂O₂ i.e.

NHPh.CO.CO.NHEt. [170°]. Formed by the action of ethylamine on phenyloxamic ether or of aniline on ethyloxamic ether (Wallach, A. 184, 66; 214, 259). Needles (from alcohol). Converted by PCl, (2 mols.) into a base which forms the salt (C10H,N.Cl)2H2PtCl.

Di-phenyl di-ethyl oxamide v. vol. iii. p. 651. PHENYL - ETHYL - PHENOL v. Oxy - DI-PHENYL-ETHANE.

PHENYL-p-ETHYL-PHENYL-ETHANE C.H.CH., CH., C, H. C H. (294°). Formed by reduction of CaH CH CO.CaH Et with HI and P (Söllscher, \vec{B} . 15, 1681). Liquid.

Isomeride. Got by the action of zinc-dust on a mixture of cthyl-benzene and a-bromo-ethyl-benzene (Radziszewski, B. 6, 811; 7, 140). Gives p-henzoyl-benzoic acid on oxida-

PHENYL-ETHYLPHENYL-ETHYLENE

PHENYL p-ETHYLPHENYL KETONE C.H., CO.C., H.Et. (831°) at 720 mm. Prepared by the action of AlCl, on a mixture of BzCl and ethylbenzen (Söllscher, B. 15, 1632; Smith, B. 24, 4029). Liquid, sol. algohol and ether. Yields two oxims [108°] and [142°], both giving the same acetyl derivative [95°]

PHENYL-ETHYL-PHENYL METHANE v.

BENZYL-ETHYL-BENZÉNE.
PHÉNYL - ETHYLPHENYL - THIO - UREA NHPh.CS.NH.C.H.Et. [104°]. Formed from p-ethyl-phenyl-thiocarbimide and aniline in alcohol (Mainzer, B. 16, 2020). Plates.

PHENYL-DI-ETHYL-PHOSPHINE

PHENYL-DI-ETHYL-PHOSPHINE
PEt.C.H., (222° cor.). S.G. ¹² -957. Formed
from C.H., PCl., and Z.MEt., (Michaelis, B. 8, 493;
A. 181, 845). Oil. Absorbs oxygen from air,
yielding O.P.Et., C.H., [50°]. Combines also with
Ol and S. forming crystalline C.₁H.₁, PCl. and
C.₁H.₁, PS. — B'2HCl. — B', H., PtCl., — B'HI. —
B'ELI. [115°].—B', 2Et., PtCl., — B'MI. [95°].—
W.M.S. PtCl. B',Me,PtCl,

Di-phenyl-ethyl-phosphine PEtPh,. (298°). Formed from Ph.Pol and ZnEt, (Michaelis a. Link, A. 207, 214). Liquid, sol. alcohol and ether. Yields OPEIPh, on oxidation. Etl yields Ph.PEt.I [204°] which gives (Ph.PEt.Cl),PECI, [218°]. MeI gives Ph.PEtMcI [181°] S. 1·5 at 22°; 50 at 100°, which gives (Ph.PEtMcCl),PtCl, [220°] and Ph, PEtMe.O.C, H, (NO,), [86°

Di-phenyl-ethyl-phosphine oxide PEtPh.O. [121°]. Formed as above, and also by the action of Ag.O on Ph, PEtl (Michaelis a. Soden, A. 229, 817). Prisms, sol. ether and ligroin.

PHENYL-DI-ETHYL PROPENYL TRISUL-PHONE PhSO₂CH₂.CMc(SO₂Et)₂. [128°]. Got from EtSH and PhS.CH₂.CO.CH₃, the product being oxidised (Autenrieth, B. 24, 169). Plates.

Di-phenyl ethyl propenyl trisulphone

Bi-paenyi etayi propenyi atsunanace EtSO_CH_CMc(SO_Ph)_ [139°]. Made in like manner from PhSII and EtS.CH_CO.CH_.

Needles (Auterrieth, B. 24, 1513).

TRI PHENYL ETHYL PROPYL-DI-THIO-BIURET C_5_N_Ph_EtPr. The (a)- compound [166°] is formed by the action of di-phenylpropyl-thio-urea on CICS.NPhEt, while the (B)compound [165°] if got from di phenyl-chyl-thio-urea and CICS.NPhPr (Billeter a. Strohl, B 21, 109). Both crystallise in needles, v. sol. hot alcohol

DI - PHENYL - ETHYL - PROPYL - THIO-UREA NPhEt.CS.NPhPr. [66"]. Formed by the action of CSCl, on propyl-aniline followed by ethyl-aniline or vice versa (Billeter a. Strohl,

B, **21**, 103).

PHENYL-ETHYL-PYRAZOLE C, H, N, i.e. NPh < CEt:CH (274°). S.G. 15 1.064. Formed from phenyl-hydrazine and propionyl-acetic aldehyde (Claisen a. Stylos, B. 21, 1148). Oil. PHENYLETHYL-PYRIDINE

cor.). S.G. 2 1 0465. Formed by reducing styrylpyridine with HI (Baurath, B. 21, 821). Liquid, sl. sol. water, volatile with steam. B'aH.PtCl. [186°]. B'HAuCl., [150°]. Long yellow needles.

B'HHgCl., [149°].

Hexahydride C₁₈H₁₈N. (288° cor.). S.G.

9.9874. Got by reducing the preceding base in alcohol with Na. Liquid, smelling like piper-

idine, sl. sol. water. Turns moist litmus blue Has toxic properties similar to those of conine Forms an oily hitrosamine. Yields pariding carboxylic acid on oxidation.—B'HCl. [155°]
-B'₂H₂PtCl₄. [189°].—B'HAuCl₄. [134°].

TETRA-PHENYL-ETHYL-PYRROLE

NEt CPh: CPh. [221°]. Formed by heating bidesyl with aqueous NBtH2 at 150° (Fehrlin B. 22, 555). Needles (from enloroform) of plates (from HOAc).

DI-PHENYL-ETHYL-PYEROLE DI-o-CARB-

OXYLIC ACID C., H., NO., i.e.

NEt C(C, H., CO, II):CH [220°]. Formed by heating C, H. (CO, C, H., CO, II), with ethylamine solution (Baumann, B. 20, 1488). Yellow plates from alcohol), insol. water. - Ag2A".

PHENYLETHYL QUINOLINE

cducing styryl-quinoline with HI (Heymann a. Königs, B. 21, 1426). Crystals.—Picrate. [c. 130°]. Yellow prisms, sl. sol. alcohol.

PHENYL-ETHYL SULPHIDE Ph.S.Et. (201° i.V.) at 744 mm. S.G. 1.0 :1.032. Formed by heating PhSNa with EtI in sealed tobes at 120° (Beckmann, J. pr. [2] 17, 457). Obtained also by the action of H₂S at 50° on C₆H₂.SO.OEt (Otto a. Rössing, B. 20, 2275) and by the action of EtSH on C, H, N,Cl (Stadler, B. 17, 2078). Liquid, with nasty smell.

Sulphonic acidC2H3.S.C6H4.SO3H. Formed by boiling C.H.S.N., C.H., SO, Na with

alcohol. - NaA': plates.

Phenyl ethyl disulphide PhS,Et. Formed together with Et.S. by heating C.H.SO.H with EtSII at 100° (Otto a. Rössing, B. 19, 3135; 20, 189). Heavy oil. Decomposed by alcoholic potash into EtSII, Ph₂S₂ C₄H₃SO₂H, and ethane sulphinic acid.

PHENYL ETHYL SULPHONE C, H, SO, i.e. C.H., SO., C.H., [43°]. (above 300°). Formed from C.H., SO, Na and Ethr er C.H., OBr., CO., Na (Otto, B. 13, 1274; J. pr. [2] 40, 535). Formed also from C.H., C.H.(SO, Ph.). C.O., H by the action of alkalis and by oxidising PhSEI with dilute KMnQ, (Beckmann, J. pr. [2] 17, 458). Monoclinic plates (Fock, B. 19, 1230), sol. hot water, v. sol. alcohol.

a-Carboxylic acid C.H., SO, CHMe, CO.H. a-uarboxynic acia C_aH₁,NO_aCHMo.CO_aH.

Phenyl sulphono-propionic acid. [116°]. Formed
by saponifying its ether, which is got from
C_aH₃SO_aNa and CH_aCHBr.CO_aEt (Otto, J. pr.
[2] 40, 548). Groups of needles, v. sol. how

water.—NaA'.—BaA', 2aq: leafy aggregates,

Ethyl ether Eth'. [c. 17°]. Oil.

B₂Carboxylic acid C_aH₃SO_aCH₄CH₂CO₂H.

[124]. Formed from benzene sulphinic acid

[124]. Formed from benzene sulphinic acid and \$\beta\$-iodo-propionic acid (Otto, \$\bar{B}\$. 21, 95). Plates, sl. sol. cold water, m. sol. ether.

PHENYL-ETHYL-THIAZOLE C,H, NS i.e. N CEt.S (296° cor.). Formed from thiopropionamide and bromo-acetophenone in alco-

hol (Hubacher, A. 259, 231). Oil.—B.H.PtCl. [129³].—B'HBr. [70³]. White needles.
TRI-PHENYL-DI-ETHYL-DI-THIO-BIURET
NPhEt C(NPh).S.OS.NPhEt. [158³]. Formed from NPhEt.CS.Cl (2 mols.) and aniline (1 mol.)

billeter a. Strohl, B. 21, 108). Yellow needles, aniline hydrochloride and potassium sulpho-. sol. alcohol.

PHENYL-ETHYL-THIOCARBAMIC ACID PhEt.CS.OH.

Ethyl ether Eth. [18]. (143° at 12 m.). S.G. 15 1066. Formed from NPhEt.CS.Cl nd NaOEt (Billeter a. Strohl, B. 20, 1629; 21, 04). Crystals.

Phenyl-ether PhA'. [69°]. Formed from he chloride and phenol. Flat needles.

the chloride and phenon. The last little of the Philades Philades Philades (Prisms (from groin), Converted by alcoholinto (NPhEt.CS), O 143°], S. (alcohol) 7 at 15°.

Phenylethyl-thiocarbamic acid. Phenylthylamine salt

PIELCS.SH. Ethyt ether Eth.* [67°]. (305° 315). Phonyl-dischtyl-4-thio-urea
**Corned by heating NPh:C(NPhet).Set with body and Etl (B.). B'HI. -B.H.PtCl., [148°].
S. at 160° (Bernthsen a. Friese, B. 15, 568, B'C.H.N.3O., [170°]. Formed also from NPhEt.CSCl and VaSEt (B. a. S.). Prisms (from ether). Forms rerystalline compound with MeL.

Phenylether PhA'. [127]. Formed from PhEt.CS.Cl and PhSH (B. a. S.). Needles.

PHENYL-ETHYL-THIO-SEMI-CARBAZIUE NHEt.CS.NH.NHPh. [1227]. Formed from ethylhiocarbimide and phenyl-hydrazine (Dixon, C. J. 55, 302). White crystals, v. sl. sol. water. FeCl, gives a red colour changing to blackishgreen.

NHPh.CS.NH.NHEt. Isomeride Formed from phenyl-thiocarbimide and ethylaydrazine (Fischer, A. 199, 296). Needles.

Di-phenyl-ethyl-thio-semi-carbazide NPhENH.CS.MIII. [149°]. Formed from a phenyl-ethyl-hydrazine and phenyl-thio-4-phenyl-ethyl-hydrazino and phenyl-thio-arbimide (Alchaeis a. Philips, A. 252, 273).

PHENYLETHYL-THIO ARBIMIDE

C.H.Ph.NCS. Formed from phenylethyl-amine by successive treatment with CS, and HgCl, (Neubert, B. 19, 1825). Yellow oil.

PHENYL ETHYL DITHIOCARBONATE

CS(OEt)(SPh). Formed by mixing solutions of C.H. N.Cl and potassium ethyl dithiocarbonate at 0° (Leuckart, J. pr. [2] 41, 186). Reddishyellow oil, sl. sol. water, slightly volatile with steam. Converted by heating with alcoholic NH_a into phenyl mercaptan and ammonium sulphocyanide.

PHENYLETHYL-THIOHYDANTOIN

 $C_{2}H_{*}Ph.N;C<_{NH,CO}^{S-CH_{2}}$ UnH,2N2SO CS < N(C,H,Ph).CH, The hydrochloride B HC)

[138°] is formed from phenylethyl-thio-urca and chloro-acetic acid (Neubert, B. 19, 1822). PHENYL-ETHYL-THIOPHENE C, High i.e.

S<CPh:CH CH:CEt [40°]. Obtained by heating CH_Bz.CHEt.CO,Na with P.S. (Dittrich a. Paul, B. 21, 3457). Small plates. Gives a cherry-red colour with Satin and H.SO, and a bluishgreen colour with phenanthraquinone and prisms, m. sol. cold water. HOAc.

HENYL-ETHYL-THIO-UREA C.H. N.S. i.e. NPhEt.CS.NH, [1180]. Formed from ethyl- (Gebhardt, B. 17, 3039). Needles.

evanide (Gebhardt, B. 17, 2094). Large pearly prisms (from alcohol).

Benzoyl derivative NPhEt.CS.NHBz. 134°]. Formed from chylaniline and benzoyl-thiocarbinide (Dixon, G. J. 55, 305). Palelemon-yellow prisms, insol. water, sol. alcohol. NHPh.CS.NHEt

s-Phenyl-athyl-thio-urea [99°]. Formed from phenyl-thiocarbimide and NH.Et and from ethyl-thiocarbimide and aniline (Weith, B. 8, 1524; Michael a. Palmer, Am. 6, 260). Monoclinic crystals.

Phenylethyl-thio-urea NH. CS. NH. C. H. Ph. [123°]. Formed from phenylethyl-amine hydrochloride and potas ium sulphocyanide (Neubert, B. 19, 1822). Plates (from dilute alcohol).

H. Ph.NH.CS.SNH, C₂H.Ph [130°]. Formed rom phenylethylamine and CS₂ (Neubert, B. 19, 1823). Flate (from diffure alcohol).

Phenyl-ethyl-di-thio-carbamic acid (PhEt.CS.SH.

Phenyl-ethyl-di-thio-carbamic acid (PhEt.CS.SH.

Phenyl-diethyl-di-thio-urea and Ed. (Bertram, B. 25, 55). Yields mercaptan on treatment with alkalis. B'HI. [103°]. B'C₂H₂N₂O₂. [196°].

Phenyl-diethyl-d-thio-urea

B'C_cH_aN₃O₇. [170°]. Phenyl-tri-ethyl-ψ-thio-urea

NPhEt.C(SEt):NEt. (c. 275°). Got from the preceding and Etf (B.). B'C, 11, N, O, [c. 96°]... B', H, PtCl, . [1352]

Di-phenyl-ethyl-thio-urea NHPh.CS.NPhEt. [89]. Formed from phenyl-thiocarbimide and ethyl-aniline (Gebhardt, B. 17, 2090). Crystals.

Di-phenyl-cthyl-4-thio-urea NHPh.C(SEt):NPh. [79°]. Formed from diplicingle-thio-urea and EtBr (Rathko, B. 14, 1776) and by the action of mercaptan on C(NPh), in the cold (Will, B. 15, 1308). Needles (from dilute alcohol). Decomposed by heat into C(NPh), and EtSH. Cl passed into a solution of its hydrochloride yields ethane sulphonic acid. BHCl.- B'2H,PtCl,2aq.-B'III aq. [157.5°] (Bernthsen, B. 15, 266, 567).

Di-phenyl-di-ethyl-thio-urea CS(NEtPh), [75.5°]. Formed from NPhEt.CSCI and ethylaniline at 100' (Billeter, B. 20, 1631). White tables (from ligrom) or needles (from alcohol).

Di-phenyl-di-ethyl-thio-urea CS(NH.C. II.,Ph). [84°]. Formed from phenylethyl-amine and alcoholic CS. (Neubert, B. 19, 1824). Plates (from alcohol), insol. water.

Acetyl derivative C19H22N2SO. [73°].

Di-phenyl-di-ethyl-v-thio-ur-a NPhEt.C(SEt):NPh. Oil. The hydro-iodide. got by heating di-phenyl-ethyl-v-thio-urea with Etl at 130°, is crystalline (B. a. F.).

u-PHENYL-ETHYL-UREA NPhEt.CO.NIL. [626]. Formed from ethyl-aniline hydrochloride and potassium cyanate (Gebhardt, B. 17, 2095).

s-Phenyl-ethyl-urea NPhH.CO.NEtH. [99°]. Formed from ethyl cyanate and aniline (Wurtz, O. R. 32, 417). Needles (from dilute alcohol). Yields a nitrosamine NPhH.CO.NEt.NO [60°] crystallising in monoclinic prisms (E. Fischer, A. 199, 286).

Phenylethyl - urea NH .. CO.NHC.H.Ph. [112°]. Formed from B-phenyl-ethyl-amine and potassium cyanate (Spica, G. 9, 568). Flat

Phonyl - di - ethyl - urea NHPh.CO.NEt, [85°]. Formed from phenyl evanate and NHEt,

Di-phenyl-ethyl-urea NHPh.CO.NPhEt. [91°]. Got from phenyl cyanate and ethylaniline (Gebhardt, B. 17, 2093). Prisms.

s-Di-phenyl-di-ethyl-urea CO(NPhEt)...
[79°]. Formed from NPhEt.COCl and ethylaniline at 130° (Michler, B. 9, 712). Crystals. NPh. CO.NEt. u-Di-phenyl-di-ethyl-urea

1.11-pnenyl-al-etayl-ures NPh, CO.Nitt.

[54]. Formed from NPh, COCl and NHEL.

Dippenyldiethyl-ures NH, CO.N(C,H,Ph),

[109]. Formed from diphenyldiethylamine hydrochloride and potassium cyanate in aqueous solution (Spica, G. 9, 568). Prisms, sol. hot Aq.

Tri - phenyl - ethyl - urea NPh...CO.NPhEt. [899]. Formed from NPh.COCl and ethylaniline (M.). Formed also from NPhEt.CeCl and diphenylamine (Kaufmann, B. 14, 2185).

PHENYL-FORMAMIDE v. vole ii. p. 568.
DI-PHENYL-FORMAMIDINE C₁₃H₁₂N₂ i.e. CH(NPh)(NHPh). Di-phenyl-methenyl-diamine. Mol. w. 196. [138°]

Formation .- 1. By heating chloroform with aniline for 12 hours at 190° (Hofmann, Pr. 9, 229) .- 2. By heating aniline with phenyl-carbamine, with orthoformic ether, or with formic acid (Weith, B. 9, 454; Wichelhaus, B. 2, 116).—3. By passing gaseous HCl into heated formic anilide (Wallach, B. 15, 208) .- 4. From formic anilide and PCI, (Wallach, A. 214, 233). 5. From CH(NPh)SEt and aniline (Wallach a. Wüsten, B. 16, 146). -6. From aniline and CH(NH,Cl)OEt (Pinner, B. 16, 358).

Properties. - Needles (from ether). Yields

B'HCl and B',H,PtCl,

PHENYL-FORMAMIDOXIM C,H,NO i.e. CH(NOH), NHPh. [116°]. Formed from thioformanilide and hydroxylamine (Müller, B. 22, 2411). Needles, m. sol. water. -B'HCl; needles. --B',H,PtCl,: yellow needles.

Bensoyl-derivative CH(NOBz)(NHPh). Needles, m. sol. alcohol and ether.

DI-PHENYL-FORMAZIDINE C₁₇H₁₇N, i.e. CH(N,HPh).N,H,Ph. [185°]. Formed from CH(NH,Cl).OEt and phenyl-hydrazine (Pinner, B. 17, 2002). Yellow plates, v. sol. hot PHENYL-FORMYLACETIC ETHER Yellow plates, v. sol. hot alcohol.

CHO.CHPh.CO₂Et. (145° at 16 mm.). Got, together with an isomeride [71°], by the action of NaOEt on a mixture of formic and phenylacetic ethers (Wislicenus, B. 20, 2931). Liquid. FeCl, colours its alcoholic solutions bluishviolet. Phenyl-hydrazine forms oxy-di-phenylpyrazole.

DI-PHENYL-FUMARAMIC ACID v. FUMARIO ACID.

PHENYL-FUMARIC ACID C, H,O, i.c. CO.H.CPh:CH.CO.H. [161°]. Got by heating bromo-cinnamic ether with alcoholic KCy for 8 hours at 150° (Barisch, J. pr. [2] 20, 186). Got also by heating CO.H.CPh(OH).CH. CO.H (Alexander, A. 258, 82). Nodules (from water).

Di-phenyl-fumaric acid

CO2H.CPh.CPh.CO.H. [c. 260°]. Formed from its ether, which is got, together with di-phenyl-malete ether, by the action of Na on a-bromo-phenyl-acctic ether (Rügheimer, B. 15, 1626). Crystals, decomposing at 260° into water and di-phenyl-maleïc anhydride.

Nitrile CN.CPh:CPh.CN. [158°]. Got by adding alcoholic NaOEt to a-chloro-phenylapetonitrile (Michael a. Jeanprêtre, B. 25, 1680).

DI-PHENYL FURAZANE $\begin{array}{c} \text{CPh:N} \\ \text{CPh:N} \end{array} > 0. [94]$ Formed by heating the (a)-di-oxim of benzil with water at 210° (Dodge, A. 264, 180). Crystals At 300° it forms di-benzenyl-azoxim. H2SO

and HNO, give a di-nitro derivative [220°]. CH:CPh CH:CPh DI-PHENYL-FURFURANE

[91°]. (345°). Formed by heating CPh:C.CH(6O₂H).CO.C₆H, or CH₂Bz.CH₂Bz with conc. HClAq at 160° for 3 hours (Kapf a. Paal, B. 21, 1490, 3057). Got also by heating its dicarboxylicacid (WeH. Perkin, jun., a. Schlosser, C. J. 57, 954). Pates, insol. water.

Tetrahydride C₁₆H₁₆O. (321°). Got by reducing with Na and alcohol. Oil.•

Octohydride C16H20O. Oile Tri-phenyl-furfurane C22H16O i.e.

CPh:CH O. [93°]. Mol. w. 263 by Raoult's CPh:CPh method (calc. 296). Formed by boiling CPhBz:CHBz with HIAq (Japp a. Klingemann, method C. J. 57,675). Got also from desyl-acetophenone by successive treatment with H.SO, and water (Smith, C. J. 57, 645). Needles (from alcohol). Tera-phenyl-furfurane v. LEPIDEN.

DI-PHENYL-FURFURANE CARBOXYLIC ACID CO2H.C:CPh O. [217°]. Formed by boiling CPh:C.CHBz.CO.H with conc. HClAq and alcohol (Kapf a. Paal, L 21, 1489, 3059) Formed also by heating the dicarboxylic acid (W. H. Perkin, jun., a. Schlosser, C. J. 57. 952). Needles (from alcohol), insol. water. May be

Macades (from account), insot. water. May be distilled. Bryields C₁₇H₁₂Br₁O₃.—NaA': needles.

Ethyl ether Eth. [82]. Formed by boiling CH₂Bz.CHBz.CO₂Et with alcohol and HClAq. Crystals (from ether). Yields on reduction a tetrahydride which does not react with AcCl.

Di-phenyl-farfurane dicarboxylic acid C₁₈H_{1.}O₅ i.e. CO₂H.C:CP₂h O. [236]. Formed by dissolving di-benzoyl-succinic ether in H2SO, and boiling the product with alcoholic potash (W. H. Perkin, jun., C. J. 47, 262; 49, 168; 57,

951). Needles, sol. alcohol and ether. FeCl, gives an orange colour in its alcoholic solution. Yields acctophenone on distilling with sodalime. - Ag₂A"

Ethylether Et.A". [86°]. Formed from dibenzoyl-succinic acid and H₂SO₄. Yellow prisms, v. sol. alcohol. Its solution in H₂SO₄ turns violet on heating.

Anhydride C₁,H₁₀O₄, [255']. Formed by heating the acid alone or with Ac₂O. Plates, sl. sol. hot alcohol. Its alcoholic solution c₂. hibits violet fluorescence.

PHENYL - FURFURYL - ACRYLIC Nitrile. C.H.O.CH:CPh.CN. [43°]. Formed from phenyl-acctonitrile, furfuraldehyde, and NaOEt in alcohol (Frost, A. 250, 159). Yields C.H.O.CHBr.CBrPh.CN [114°] ctstallising in orange plates.

Reference. - NITRO-PHENYL-FURFURYL-ACRYLIC PHENYL - FURFURYL - (\$) - NAPHTHO -

TRIAZINE. Dihydride C21H13N2O i.e. C, H, < N.CH.C, H,O Formed by [241°]. warming benzene-azo-(A)-naphthylamine with furfuraldehyde in alcohol (Goldschmidt a.

Poltzer, B. 24, 1007). Needles. - B'HCl: plates.
-B'_H_2PtCl_. Light-yellow crystalline pp.
(B)-PHENYL-(\gamma)-FURFURYL-PROPYLAMINE C,H_3O,CH_CHPh.CH_NH_. (283°).
Formed from pheny facetonitrile and furfuraldehyde, the product of condensation of these bodies C.H.O.CH:CPh.CN being reduced by Na and dry alcahol (Freund a. Immerwahr, B. 23, 2850). Oil, with alkaline reaction. Converted by nitrous acid into the liquid alcohol C₄H₂O.CH₂.CHPh.OH.OH. Phenyi thiocarbin-ide forms C₄H₂O.C₄H₂Ph.NS.CS.NHPh [113]. - B'HCl. [176°]. Crystalline, v. sol. water. Reacts with potassium cyanate forming C4H4O.C3H.Ph.NH.CO.NH2 [101]. - Mercury Gitj.O., Il., rantoo. ang. [137]; needles. — Picrata [152]. Yeflow crystalline powder. PHENYL-FURIDANE. Dihydride

CPh CH.CH. CH₂ • (250° at 721 mm.). Formed by heating its carboxylic acid at 2000 (Perkin, G. J. 51, 731). Oil. HBr forms CH.CO.CH.Br.

PHENYL-FURIDANE DIHYDRIDE CARB-

CO2H.C CH2CH2CH2 ACID · OXYIJC

Phenyldchydrohe cone carboxylic acid. [c. 144]. l'ormed by saponifying its ether, which is ot by the action of NaOEt on a mixture of trimethylene bromide and benzoyl-acetic ether (Perkin, C. J. 51, 726). Monoclinic prisms -AgA': needles (from water).

Ethyl ether Eth', [60°]. Prisms. PHENYL-GLUTARIC ACID $C_0H_{12}O_1$ i.e. CHPh(CH2.CO2H)2. [1382]. Formed by heating sodium malonic ether with alcohol and cinnamic ether at 100°, saponifying the resulting ether CH(CO_Et)_CHPh.CHNa.CO_Et, and heating cthera to the control of the acid at 110 (Michael, J. pr. [2] 35, 352; Am. 9, 110). Needles, sl. sol. water, m. sol. alcohol. -AgA*: amorphous pp.

Di-phenyl-glutaric acid Clf_(CHPh.CO.H), [164*]. Formed by saponifying its nitrile (Zelinsky a. Feldmann, B. 22, 3292). Needles. Nitrile CH_(CHPh.CN), [71*]. Formed by heating CH_Ph.CN with CH_L and dry NaOH, PHENYL-GLYCERIC ACID v. fit-oxy.

PHENYL-PROPIONIC ACID.

TRI-PHENYL GLYCERYL TRIKETONE CH_Bz.CHBz.CH_Bz. Tri-benzeyl-propane. [137°]. Formed from tricarballylic chloride, benzene, and AlCl₃ (Emery, B. 21, 601). Strawyellow needles. Yields a phenyl-hydrazide [57°-60°].

PHENYL-GLYCIDIC ACID C.H.O., i.e. O CHPh Phenyl-pyravic acid? [155] Formed by boiling benzoyl-imido-phenyl-propionic acid NBz CHPh with aqueous HCl or with KOH (Plöchl, B. 16, 2817; 19, 3167). Formed also by boiling phenyl-oxalactic acid with dilute H₂SO₄ (W. Wisticenus, B. 20, 592). Plates, v. e. sol. alcohol and ether. FeCl, colours its alcoholic solution green. Sodium smalagm reduces it to geoxynbenyl-propionic amalgam reduces it to a oxy-phenyl-propionic seid. Yields an oxim and a phenyl-hydrazide CHPh.C(N,HPh)CO.H [161]. Tolylene-o-di-amine forms a quinoxaline (Erlenmeyer, jun., B. 19, 2576; 20, 2465; 22, 1482). Aniline forms C,H,Ph(NHPh)(OH).CO,H.

 (β) -Phenyl-glycidic acid. Formed from C.H.CH(OH).CHCl.CO.H and cold alcoholic potash (Glaser, A. 147, 98). Oil, crystallising at 0°. Decomposes, even at 15°, into phenylacctic aldehyde and CO.. Boiling dilute H.SO. forms CHPh(OH).CH(OH).CO.. It and phenylacetic aldehyde (Erlenmeyer a. Lipp, 4. 219, 181)? Yields β-oxy-phenyl-propionic acid on reduction with sodium-amalgam. - NaA' .-- KA'. -AgA': crystalline powder.

Ethyl other EtA'. (280° cor.). Oil. References .- NITRO- and OXY- PHENYL-GLY-

CIDIC ACID. PHENYL-GLYCOCOLL v. PHENYL-AMIDO-

ACETIC ACID.

PHENYL-GLYCOL v. DI-OXY-ETRYL-BENZENE.
PHENYL-GLYCOLLIC ACID v. Phenylderstative of GLYCOLLIC ACID and MANDELIC

Di-phenyl-glycollic acid v. Benzillo acid. PHENYL-GLYCOLLIC ACRYLIC ACID v. Carboxy-methyl derivative of Coumanic Acid.

PHENYLGLYCOLYL-TROPEINE C18H21NO. Homo-atropine. [98"]. Formed by heating tropine mandelate with HClAq (Ladenburg, A. 217, 82). Deliquescent prisms (fron ether), m. sol. water. Less poisonous than atropine .-B'HAuCl. -B'HBr. -B'C, H, N, O, Yellow plates. TETRA-PHENYL-GLYCOSINE v. GLYCOSINE.

PHENYL-GLYOXAL C.II. CO.CHO. (142° (from ether); a:b:c=2.638:1:3.398; $\beta=74.3.44$ '. •at 125 mm.). Formed by allowing a mixture of its mono-oxim (30 g.) with NaIISO, (120 g. of a 35 p.c. solution) to stand till all is dissolved, and then adding H.SO, and distilling (Müller a. von Pechmann, B. 20, 2904; 22, 2557). Oil. Forms a crystalline hydrate [73°]. Converted by HNO, into phenyl glyoxylic acid, and by potash into mandelic acid. Ammonia forms C₂₂H₁₉N₃O or C₂₂H₁₀N₃O crystallising in plates [193] which can be distilled. Hydroxylamine

gives C₁₅H₁₃N₃O₃, [219°], sol. alkalis. Mono-oxim C₅H₅.CO.CH:NOH. acetophenone. [128°]. Formed from acetophenone, isoamyl nitrite, and alcoholic NaOEt (Claisen, B. 20, 656, 2194; Braun, B. 22, 556). Monoclinic tables (from chloreform), sl. sol. cold water, v. sol. alkalis. Yields C.H., CO.CN on warming with Ac.O. Boiling NaOHAq forms NaCy and NaOBz. Its acetyl derivative is converted by NaOHAq into CHBz(OH).CO.CO.C.H. [170°] crystallising in minute needles (Söder-

baum, B. 24, 1386, 3034). Di-oxim CaH, C(NOH).CH(NOH). phenyl-amphi-glyoxim. [162°] (S.); [168°] (R.). Formed by the action of hydroxylamine on the mono-oxim, or on mono- or di-bronio- acetophenone (Schramm, B. 16, 2183; Strassmann, B. 22, 419; Russanoff, B. 21, 3501). Small needles, v. sol. alcohol, insol. CHCl,; subliming below 160°. N₂O, gives C₆H₂.C₂HN₂O₂ [c. 90°] crystallising in colourless prisms (Scholl, B. 23, 3504). By dissolving in ether and treating with HCl it is converted into an isomeride [180°]. This body, called phenyl-anti-glyoxim, is v. sol. Ac₂O and yields a di-acetyl derivative [92°]. Phenylanti-glyoxim is only stable in acid solutions being readily re-converted into the original di-oxim [168°]. By treatment of the di-oxim [168°] NaOHAq and CO₂ at -10° there is formed a

second isomeride (148°-154°) called phenyl-synglyoxim which yields an oily di-acetyl deriva-tive.—AgC, H,N,O,. Curdy pp.

Phenyl-hydrazide C,H, C(N,HPh).CHO.
[148]. Yellow plates (M. a. P.).

Phenyl-hydrazide C,H,.CO.CH;N2HPh. [129°]. Formed by the action of warm dilute KOHAg on the compound got by treatment of sodium benzoylacetic ether with diazobenzene chloride (Stierlin, B. 21, 2123). Yellow plates. p-Tolyl-hydrazide CHBz:N.H.C.H.,Me.

Got in like manner, using p-diazotolucne chloride. Yellowish-brown plates, v. sol. ether.

Di-phenyl-di-hydrazide C.H.C(N,HPh).CH(N,HPh). [1522]. Got by heating phenyl-glyoxal or, better, the phenyl-hydrazide of benzoyl-cathinol with phenylhydrazine hydrochloride and NaOAc at 100°

(Laubmann, A. 243, 247). Yellow plates.
Di-phenyl-di-methyl-di-hydraz?de
Cath, C(N_Mclh), CH(N_Mclh). [151*]. Formed
from w-bromo-acctophenone and phenyl-methylhydrazine (Culmann, B. 21, 2597). Prisms.

Di-phenyl-glyoxal v. Benzu. PHENYL-GLYOXALINE C, II, N2 i.e. •

 $C_{\bullet}H_{\bullet}N <_{\mathrm{CH};N}^{\mathrm{CH};\mathrm{CH}}$. [13°]. (276°). Formed by

warming sulphydro-phenyl-glyoxaline [181°] with dilute HNO, or HClAq (Wohl a. Marek-wald, B. 22, 576, 1353). Crystalline, miscible with alcohol. B'HAuCl₄.—B'₂H₂PtCl₆.—Picrate B'C₆H₃N₃O₇. [152°]. Yellow needles (from alcohol).—B, AgNO, —B'MeI. Syrup.

Phenyl-glyoxaline NII CH :CH (c. 340°). Formed by distilling its dicarboxylic acid, which is got from di-nitro-tartaric acid, benzoic aldehyde, and NH, (Maquenne, C. R. 111, 742). Plates (from benzene). - $B'_{2}H_{2}C_{2}O_{1}$. Needles. - $B'_{2}H_{2}PtCl_{6}$.

Di-phenyl-glyoxaline $\mathrm{CH} \leqslant_{N-CPh}^{NH,CPh}$. [227°].

Formed by the action of formic aldehyde and ammonia on benzil (Japp, C. J. 51, 559). morphous. Crystallises with di-phenyl-methylglyoxaline as (C₃N.H₂Ph₂)C₃N₂HMePh₂ [218]. -B'2H2P(Cla: small flat yellow needles.

p. 474.

PHENYL-GLYOXIM v. Oxim of PHENYL-GLYOXAL.

PHENYL-GLYOXYLIC ACID C.H.O. C.H. CO.CO.H. Benzoyl-formic acid. [66°].

Formation .- 1. From benzoyl evanide and conc. HClAq in the cold (Claisen, B. 10, 429, 844, 1663; 12, 626, 1505) or HOAc saturated with HCl (Buchka, B. 20, 395).—2. From dioxy-ethyl-benzene (phenyl-glycol) and nitrio acid of S.G. 1-38 (Zincke, A. 216, 305).—3. By saponitying its ether, which is got by heating COCLCO. Et with HgPh, for several hours at 150°; the yield being 40° p.c. of the theoretical (Glaisen a. Morley, B. 11, 1596). - 4. By oxidising acctopherone with alkaline KMnO, at 0°; the yield being 20 p.c. of the theoretical amount (Glückmann, M. 11, 248).

Properties. -- Prisms, v. e. sol. water and ether. Decomposed by distillation into benzoic acid and CO, and partly also into benzoic aldehyde and CO. Phenyl-hydrazine added to its solution in dilute HCl forms a bulky yellow pp.

of phenyl-hydrazide (Ebers, A. 227, 340). When mixed with benzene (containing thiophene) i gives with conc. H.SO, a red colour changing t violet. On adding water, the layer of benzen becomes crimson.

Reactions. 1. Sodium amalgam reduces i to mandelic acid.— 2. HI and P at 160° reducit to phenyl-acetic acid.—3. Phenyl mercaptar and gaseous HCl form C₈H₂C(SPh). CO₂E [142^o], sl. sol. benzene (Baumann, B. 18, 891) Phenyl mercaptan alone forms a crystalline powder C₀H₁,C(OH(SPh).CO₂H [69°]. Salts.—NaA'O—KA'aq: dimetric tables.—

NH₄A'.—CaA'₂aq₁flat prisms.—BaA'₂.—SrA'₂aq —CuA'₂.—ZnA'₂2aq.—PbA'₂.—PbA₂aq.—AgA' Methyl ether MeA'. (218°). Ethyl ether EtA'. (257'). S.G. 175 1·121. Forms a crystalline compound with NaIISO₂. Redets in alcoholic solution with hydrazine neates in actionic solution with hydrate forming C, H₁₂N₂O₁ [120°] and C₂₂H₂₂N₂O₁ [135°] (Curtius, J. pr. [2] 44, 566).

n. Propyl ether PrA. (174° at 60 mm.).

Isoanyl ether. (174° at 38 mm.).

Isoanyl ether. (182° at 40 mm.).

(a) Amide C.H. CO.CONH. [91]. Formed from benzoyl cyanide and cold HClAg. On solution and re-ppn. by CO2 it forms an unstable

hydrate C_sH NO. aq [65°] (so-called (β) amide).

• (γ) - Amide (C_sH , NO.). [134°]. Formed by adding an alcoholic solution of the (a)-amide to dilute HClAq (Claisen). Formed also, together with the (a) amide, by the action of HOAc saturated with HCl upon BzCy (Buchka). Prisms.

Nitrile v. BENZOYL CYANIDE. (a) - Oxim C, II, C(NOII).CO, II. Isonitrosophonyl-acetic acid. [127]. Formed by the action of hydroxylamine on the Na salt (A. Müller, B. 16, 1617) or on the acid at '0° (Hantzsch, B. 23, 2333; 24, 42). Thick wisms, v. e. sol. water. Yields a amido-phenyl-acetic acid on reduction. - KA'ag: very soluble crystals. -BaA', 1 aq. -AgA'.

Acety derivative. [119]. Prisms.

(β) - O. rim C₆H₃, C(NOM), CQ₂H• [145⁸]. Formed by the action of HCl on an ethereal solution of the (a) oxim. Formed also by warming phenyl-glyoxylic acid with hydroxyl-Tri-phenyleglyoxaline v. Lophine, vol. i. amine and potash. White needles composed of dimetric prisms.

Acetyl derivative. [1250]. Tables. Methyl ether of the oxim

CPh(NOH).CO.Me. [139°]. Got from the Ag salt and McI (Müller, B. 16, 2987). Converted by NaOEt and MeI into Clh(NOMe).CO.Me [56°], sol. alcohol, insol. alkalis.

Ethyl ether of the oxim CPh(NOH).CO₂Et. [113°]. Formed from phenylglyoxylic ether and hydroxylamine (Gabriel, B. 16, 519). Needles (from hot water).

Nitrile of the oxim C,H,.C(NOH).CN. 129°]. Formed from phenyl-acetonitrile, amyl nitrite, and alcoholic NaOEt (Frost, A. 250, 163; Meyer, B. 21, 1306). Formed also by the action of hydroxylamine on dibromo-acctophenone in dilute alcohol at 60° (Russanoff, B. 24, 3505). Thin plates, v. sol. alcohol.—C.H., C(NONa).CN: yellow powder, v. sol. water. Yields an acetyl detivative [58°].—KA'.—CuA'₂—Pb_A₂O.—AgA'.

Phenyl hydrazide C.H., C(N₂HPh).CO.H.
[153°]. (F.); [153°-1642] (Yon Pechmani, B.
25, 1054). Yellow needles, al. sol. hot water

(Fischer, B. 17, 578; Ebers, A. 227, 340). May be reduced to C.H., CH(N.H., Ph).CO.H [158°], and finally to aniline and a amido-phenyl-acetic

Phenyl-methyl-hydrazide C₆H₃.C(N₂MePh).CO₂H₂ [116°]. Plates (from alcohol). Its amide C₆H₃.C(N₂MePh).CONH₄. [156°] is crystalline.

Phenyl-gthyl-hydrazide C.H.,C(N,EtPh).CO.H. [109°]. Formed, to-gether with its amide C.H.,C(N,EtPh).CO.NH. [111°], by the action of phenyl-cthyl-hydrazino in dilute HOAc on phenyl-glyoxylic acid. Yellow plates, sl. sol. water. Yields ethyl-aniline and benzoic aldehyde when heated with conc. HClAq.

References. -- AMIDO-, NITRO-, and OXY-

PHENYL - GLYOXYLIC o - CARBOXYLIC ACID.

ACID C_aH₁(CO₂H).CO.CO.H. [140°]. Formed by oxidising the oxyquinone C_aH₁₀O₃ or indonaphthene dibydride carboxylic acid with alka line KMnO, (Scherks, B. 18, 378; cf. Zineke, A. 226, 53, 240, 142). Yields CO, and phthalic anhydride on heating. May be reduced to phthalide carboxylic acid. -- K, A". Ban" 2aq. -Cu,A"(OH), 6aq. -Ag A": crystalline pp.

PHENYL-DIGUANIDE C, II, N. i.e. NH:C(NHPh).NH.C(NH2):NH. [c.237°]. Formed by the action of alcoholic ammonia and AgNO, or HgCl₂ on guanyl-phenyl-thio-urea (Bamberger, B. 13, 1582). Formed also by heating aniline hydrochloride with di-cyan-di-amide in alcohol at 100° (Smolka a. Friedrich, M. 9, 232). Plates, v. sol. water and alcohol; absorbs CO. from air. When boiled with baryta-water it yields NH, aniline, phenyl-urea [147], phenylguanidine, guanidine, and urea (Emich, M. 12, 15).—B'HCl: prisms. Yields phenyl-carbamine

15).—B HOI: prishes. Then phenyl-carbanine when warmed with alcoholic potash and CHCl₃.

Salts.—B'HNO₃. [209°].—B' [H SO₄.—Cu(C₃H₁₈N_{\$\)}, 14aq: red powder, sol. hot water.

— CuA'₂H₁Cl₄ 14aq.—CuA'₂H₂SO₄, 1½aq.

— CuA'₂H₂CrO₄aq.—NiA'₂.—NiA'₂H₂SO₄, 1½aq.

— NiA'₄H₂SO₄ 1¹ aq.—CoA'₂ 1½aq.

— CoA'₂H₃SO₄ aq: crimson needles.

(a) Pi neared distancial of M. M. S. (b) Pi neared distancial of M. M. S. (c) Pi neared distancial of M. M. S. (d) Pi n

(a) Di-phenyl-diguanide C₁H₁N₅ i.c. NPh:C(NHPh).NH.C(NH₂):MH. Formed by the action of AgNO, and aniline on guanyl-phenylthio-urea (Bamberger, B. 13, 1581). White solid, m. sol, water and alcohol, alkaline in reaction.—B'HNO₃. [231°]. White needles. (B)-Di-phenyl-diguanide

NH:C(NPh.).NH.C(NH.):NH. [c. 162°], Formed by heating diphenylamine hydrochloride with di cyan-di-amide (Emich, M. 12, 21). Thin medles, with alkaline reaction. - B'HNO_x. [203°]. Prisms. -B'23H2SO4.

Tri-phenyl-diguanide CzoH, No. Formed from guanyl-tri-phenyl-thio-urea, NH3, and AgNO. Formed also from di-phenyl-guanidine and phenyl-cyanamide [78°] in ether (Rathke a. Oppenheim, B. 23, 1672). Prisms (from alcohol). With CS₂ at 100° it yields triphenyl-thio-ammeline C_nH_nN,S. — B'HCl: prisms, v. sol. alcohol.—B'H.PtCl.

PHENYL-GUANIDINE C,H,N, i.e. NH:C(NH₂)(NHPh). Formed by desulphuration of phenylethio-ures in presence of alcoholic NH₂ (Feuerlein, B. 12, 1602). Formed also by the action of baryta-water on phenyl-diguanide

(Emich, M. 12, 11). Decomposes on standing into phenylcyanamide and ammonia. — Picrate B'C,H,N,O,. [208°-214°] (Prelinger, M. 13, 99).

Di-phenyl-guanidine C13H13N3 i.c.

NH:C(NHPh)... Melaniline. [147°]. S. (90 p.c. alcohol) 9.25 at 21°.

Formation.—1. From aniline and CyCl or CyBr (Hofmann, A. 67, 129; 74, 8; Weith a. Ehert, B. 8, 912). - 2. By the action of PbO on As solution of di-phenyl-urea in alcoholic NH, (Hofmann, B. 2, 452, 688; Weith, B. 7, 937; Rathke, B. 12, 772).—3. By boiling phenyl-thiourea with HgCl(NHPh) and alcohol (Forster, B. 7, 2291; A., 175, 35). -4. Together with thiourea, by the action of aniline on mercuric fulminate (Steiner, B. 7, 1244; 8, 518). 5. By confibination of di-phenyl-cyanamide with NH₃ (Weith, B. 7, 10).

Properties. Monoclinic prisms (Arzruni, P. 152, 284), se sol. cold water.

Reactions.—1. Ac.O at 100° yields acetyl-phenyl-uren [185']. At 150° the product is acetyl-di-phenyl-uren [115°] (McCreath, B. 8, 1181) 2. Phenyl thiocarbimide forms, in the NHPh.CS.NPh.C(NH).NHPh [150°], weak base, sl. sol. benzene. 3. HClAq at 250° forms CO., NII, and aniline. -4. Cyanogen passed into its alcoholic solution forms C15H13N3 which crystallises from alcohol in yellowish needles [151°], decomposed by HClAq into crystalline melanoximide $C_{13}H_{11}N_{3}O_{21}$ which is split up by alcoholic potash into oxalic acid and diphenylguanidine, and by alcoholic HCl into NH, and di-phenyl-parabanic acid.

Salts. The hydrochloride is gummy. B'HAuCl₁: golden needles. -- B'2H2PtCl₆. B'HBr: stellate groups of needles, v. sol. water. - B'HI. - B'HNO₃. - B'₂AgNO₃: geodes. - B'₂H₂SO₄: stellate groups of plates. - B'H₂C₂O₄. -Sulphocyanide: [115]; m. sol. water.

Dibenzoyl derivative C27 II21 N8O2 [102°]. Monoclinic (McCreath, B. 8, 383). Tri-phenyl-guanidine C, II, N, i.c.

NPh:C(NHPh)₂. Mol. w. 287. [143°]; [147°] (F. a. W.). S. (alcohol) 4.5 at 0°.

Formation. - 1. By adding I to an alcoholic solution of di-phenyl-thio-urea alone or mixed with aniline (Hofmann, B. 2, 453). - 2. From diphenyl-thio-urea and HgCl(NHPh) (Forster, B. 7, 291). - 3. From di-phenyl-cyanamide C(NPh)2 and aniline (Weith, B. 7, 10).-4. Together with phenyl-thiocarbimide by heating diphenyl-cyanamide with di-phenyl-urea (Weith, B. 9, 810).—5. By boiling di-phenyl-urea with inverted condenser (Barr, B. 19, 1765). -6. By heating di-phenyl-thio-urea with aniline, with Cu, or with PhCl₂ (Merz a. Weith, Z. [2] 4, 513, 609; 5, 583, 659; Gir: id, Bl. [2] 46, 506), or with Italian 145° (Buff, B. 2, 498).—7. By heating di-phenyl cyanamide (2 mols.) with phenyleneo-diamine (1 mc!.) at 210° (Keller, B. 24, 2505). 8. By the action of aniline on CCI, or chloropicrin (Hofmann; Basset, C. J. 18, 31). - 9. By the action of PCl₂ (1 mol.) on a mixture of diphenyl-urea (3 mols.) and ardline (3 mols.).—10. By the action of PCl, (2 mols.) and CO, (3 mols.) on aniline (9 mols.) at 170° (Merz a. Weith, Z. [2] 6, 160).—11. By fusing di-phenylurea with NaOH (Hentschel, J. pr. [2] 27, 500).

12. From phenyl thiocarbimide by chlorinating

and heating the product NPh:CCl₂ with aniline (Sell a. Zierold, B. 7, 1231). The base got is possibly an isomeric tri-phenyl-guanidine.— 13. A product of the action of CSCl, on CS(NHPh), and benzene (Freund a. Wolf, B. 25, 1464).

Properties .- Trimetric six-sided prisms (from alcohol); a:b:c = .670:1:.558, nearly insol. boiling water. Occurs also in an amorphous form (Giraud, Bt. [2] 46, 505). Decomposed above 250° into online and C(NPh). KClO, (1, pt.) and HCl give a greenish solution, depositing dark flakes which dissolve in alcohol with violet

Reactions.—1. CS at 170° forms CS(NPIM), and phenyl thiocarbimide—2. H.S passed through it at 170' forms aniline and di-phenyl-urea (Morz a. Weith, Z. [2] 6, 72).—3. Water at 175° forms aniline and di-phenyl-urea.—4. Conc. KOHAq or conc. HClAq yield aniling and CO2 on heating .- 5. Cyanogen passed into the alcoholic solution forms crystals of CnH1,N3 which is decomposed by HClAq into NH1 and which is decomposed by Holly NPh.CO [c. NPh] NPh.CO 230°] which is itself decomposed by boiling with alcohol and HClAq into aniline and di-phenylparabanic acid (Hofmann, B. 3, 701; Stojentin, J. 7r. [2] 32, 1).—6. Chloro-glywylic ether COCLCO, Et forms a carbonyl derivative

C(NPh) NPh CO which forms the salts B'HCl [190°] and B'HNO, [185°] (Stojentin). - 7. COCI, forms the above (?) carbonyl derivative C₂₀H₁₀N₂O, which crystallises from CS₂ in tables [134°] and forms a hydrate B' aq [141°] (Michler a. Keller, B. 14, 2181).

Salts.—B'HCl aq [242°] (Weith, B. 9, 810); [245°] (F. a. W.). S. 2 at 0°,—B'IINO,; lamine.—B'_2H_1PtCl, S. 09 at 0°,—B'II.SO,: broad needles. B'HOAc. B'H, C,O,: lamina. B'C, H, N, O,. [178°]. S. 0082 at 15° (Prelinger,

Acetyl derivative C(NPh)(NPhAc). [181°]. Crystals (MacCreath, B. 8, 383). Benzoyl derivative C(NPh)(NPhBz)2.

[185°]. Plates (from alcohol).
(β)-Tri-phenyl-guanidine
C(NH)(NHPh)(NPh.). [131°]. Formed heating phenyl-cyanamide (cyanilide) CN.MIPh with diphenylamine at 125° (Weith a. Schröder, B. 8, 912). Regular tablets, nearly insol. water. Its solution in cone. H.SO, becomes violet on heating.

Reactions.-1. Conc. HClAq or KOHAq at ! 260° forms CO, NH, aniline, and NHPh... CS₂ at 160° forms the sulphocyanide, H.S. phenyl-thiocarbimide and NHPh.

Salts.-B'HCl aq. S. (of B'HCl) 284 at

23°.-B',H,PtCl,: crystalline.

Dicyanide C₂₁H₁₇N₃. [173°]. A product of the action of cyanogen as an alcoholic solution of aniline (Hofmann, A. 66, 129; B. 3, 763). Got also by boiling the compounds of cyanogen with di-phenyl-guanidine or (a)-triphenyl-guanidine with aniline hydrochloride (Landgrebe, B. 10, 1593; 11, 973). Dark-brown needles (containing aq) with violet iridescence (from alcohol).—B'HCl 3aq: brown needles.

Tetra - phenyl - guanidine C(NH)(NPh2)2. [181°]. Formed by passing gaseous cyanogen

chloride through diphenylamine at 160° (Weith, B.7, 843). Pyramids (from ligroïn), insol. water, v. sol. alcohol and ether. Conc. H.SO, forms a colourless solution turned violet-red by heat. CS2 at 260° forms tetra-phenyl-thio-urea. Solid KOH at 200°, and con HClAq at 340°, yield NH3, CO., and NHPh2.

Salts.—B'HCl 5aq. Efflorescent tablets.—B'_H_PtCl_s.—B'HNO_s.

References. - DI-BROMO-, DI-CHLORO-, DI-10DO-, and NITRO- PHENYL-QUANIDINES.

DI-PHENYL-GUANDINE CARBOXYLIC ACID C(NH)(NH, h).NH.C, H, CO, H. Phenyl-guanido-benzoic acid. [165°]. Formed by heating m-cyanamido-benzoic acid or cyancarf bimidoamido-benzoic acid with aniline (Traube, B. 15, aq), nearly insol. alcohol and ether, sol. hot water, aqueous alkalis and acids.-HA'IICl aq.

Reference. - Amido - di - Phenyl - Guanidine CARBOXYLIC ACID.

PHENYL-GUANIDO-ACETIC ACID

[260' uncor.] Formed from phenyl-cyanamide and glycocol (Berger, B. 13, 992). Crystals, DIPHENYL-DI-GUANIDO-DI-TOLYL-SUL-

PHIDE S(C,II, NII.C(NII).NHPh)2. Thio-ptolyl-di-phenyl-di-gnanidine. [1539]. Formed by heating di-phenyl-di-uramido-di-tolyl sulphide with alcoholic NH, and HgO (Truhlar, B. 20, 675). Small white needles (from ether-ligroin). V. sol. alcohol, benzene, and ether.—B'II,Cl,PtCl,: yellow amorphous powder.

Tetra-phenyl-di-guanido-di tolyl-sulphide S(C,II, NH.C(NPh).NHPh). Thio-p-tolyl-tetraphenyl-di-guanidine. [106°]. Formed by heating di-phenyl-di-uramido-di-tolyl sulphide with aniline and HgO (T.). Amorphous powder.

PHENYL-HEPTADECYL-THIO-UREA C. H. NH.CS.NI[C., Hx., 179"]. Formed by boiling heptadecyl thiocarbimide with aniline and

alcohol (Turpin, B. 21, 2091).

PHENYL HEFTADECYL UPEA C2, H1, NO. i.e. C6, II, Nfl.CO.NHC1, H3, [99]. Formed by heating heptadecylamine hydrochloride with COCl₂ in benzete at 100°, the product being heated with aniline (Turpin, B. 21, 2492).

PHENYL-HEPTANE v. HEPTYL-BENZENE. Disphenyl-heptane C.H.; CHPh. (191° at 13 mm.). Formed from CeH13.CHCl benzene, and AlCl₃ (Auger, Bl. [2] 47, 48; Krafft, B. 19, 2986). Needles.

PHENYL-HERTENOIC ACID C .: H .: O. i.e. Ph.CEt.CEt.CO.H (?) Oil. Got by passing CO over a heated mixture of NaOEt and sodie cinnamate (M. Schroeder, A. 221, 52).

PHENYL HEPTYL KETONE CARBOXYLA ACID C.H., CO.CH. CH(C.H.,).CO.H. [103°]. Furned by heating phenacyl-isoamyl-malonic acid (Paal a. Hofmann, B. 23, 1504). Plates, insol. water, sl. sol. ligroïn. On repeated dis-

Ethyl ether Eth. (200°). Oil.

PHENYL-HEXINENE v. BUTENIL-SIYEENE. DI-PHENYL-HEXOIC CH_Ph.OPhPr.CN. [63°]. (330° 340°). Formed from C₆H₂.CHPr.CN, benzyl chloride, and NaOH (Rossolymo, B. 22, 1236). Needles. ACID.

TETRA PHENYL-HEXUNENE & CPh CH.CH CPh [269°]. Formed by heating di-benzyl-carbinol with MeI at 265° (Bogdanowska, B. 25, 1273). Needles, insol. alcohol and ether, sol. CHCl.

PHENYL-HEXYL-TRIAZOLE CARBOXYLIC

ACID CH₂(CH₂), C NNPh [126°]. tained by saponifying its nitrile, which is got from phenyl-hydrazine dicyanide and heptoic aldehyde (enanthol) (Bladin, B. 25, 186). Silvery plates, v. sol. alcohol. -CuA', aq. -HA'HCl.

Amide. [82.5°]. White plates.

Thio-amide C₁₁H₁₈N₁CS.NII... [77°].

Formed from the crude nitrile and alcoholic ammonium sulphide. Yellow plates, sol. alcohol.

DI-PHENYL-HEXYL-TRICYANIDE

 $N \leqslant_{\mathrm{CPh}:N}^{\mathrm{CPh}:N} \searrow_{\mathrm{C.}(\mathrm{CH_2})_s,\mathrm{CH_3}}^{\mathrm{CPh}:N}$ [44°]. 15 mm.). Cot from heptorl chloride, benzonitrile, and AlCl, at 70° (Krafft a. Hanssen, B. 22, 808).

PHENYL HEXYL KETONE C.H. CO.C. H. [17]. (267°) at 740 mm. Formed by the action of AlCl₃ on a mixture of benzene and heptoyl chloride (Auger, Bl. [2] 47, 50; Krafft, B. 19, 2987). Leaflets. Yields an oxim [55]. PHENYL-HEXYL-(β)-NAPHTHOTRIAZINE.

Dihydride C ... H ... N i.e. C .. U .. N. NPh ... N. NPh

[176.5°]. Formed by heating benzene-azo-(A)naphthylamine with conanthol and alcohol (Goldschmidt a. Poltzer, B. 24, 1007). Needles, sol. alcohol.—BHCl. [226°]. White needles.
—B'_2H_P(Cl_c. [225°]. Granules.
PHENYL-HEXYL-PYRAZOLE C_6H_0N_2 i.e.

 $\mathbf{C}_{a}\mathbf{H}_{13}$. $\mathbf{C} \leqslant \frac{\mathbf{CH} - \mathbf{CH}}{\mathbf{NPh} \cdot \mathbf{N}}$. (319°).Formed from heptoyl-acetic aldehyde and phenyl-hydrazine (Claisen a. Stylos, B. 21, 1149). Oil.

PHENYL-HEXYL-THIO-UREA C₁₃H₂₀N₂S i.c. (N #Ph).NH.CHaCHEt., [53°]. Formed CS(NRPh).NH.CH.cHet. [53°]. Formed from hexylamine and phenyl-thiocarbinide (Freund a. Herrmann, S. 23, 195). Prisms.

PHENYL-HEXYL-UREA C17H20N.O i.c. CO(NHPh).NII.CH,.CHEt₂. [705]. Formed from hexylamine and phenyl cyanate (Freund a. Herrmann, B. 23, 194). Needles.

PHENYL-HOMO-ITAMALIC ACID v. Oxy-BENZYL PYROTARTARIC ACID.

PHENYL-HYDANTOÏC ACID

NH₂.CO.NH.CHPh.CO₂H. [178°]. Got by boiling (a)-phenyl-hydantoin with baryta (Pinner,

B. 21, 2326). Prisms, sl. sol. cold water.

A mide NH₂:CO.NH.CHPh.CO.NH₂. [223°]. Formed by adding the compound got from urea and the cyanhydrin of benzoic aldehyde to H SO4 and pouring into water at 0' (Pinner a. Spilker, Br 22, 697). Prisms (from dilute alcohol). lields phenyl-hydantoin on heating.

PHENYL-HYDANTOIN C, H, N, O, i.e. CO NH .CO [192°]. Formed by fusing urea with phenyl-amido-acetic acid (Schwebel, B. 10, 2045). Needles, v. sl. sol. water, sol. alkalis.

(a)-Phenyl-hydantoin CO NH.CO Dioxy-phenyl-glyoxaline. [178°]. Formed by heating the cyanhydrin of benzoic aldehyde with mandelic nitrile at 100° (Pinner, B. 21, 2321). Formed also from phenyl-uramido-acethe ether and KOH (Kossel, B. 24, 4150). Needles (from HClAq). KOH and MeI yield C.H.MeN2O2 [1620], crystallising in needles .-KA': needles, v. sol. water.

Acetyl derivative C.H.AcN.O. [145°]. Small needles (from benzene), insol. water.

C(NH) < NH.CO Phenyl-\psi-hydantoin*

[above 300°]. Got by dissolving (a)-phenylhydantoïn in alcoholic potash and then adding HCl. Crystalline. $-K\Lambda'$: almost insol. water.

Atotyl derivative C(NH) CNAc.CO White prisms (Pinner a. Spilker, B. 22, 698). Decomposes at about 290".

PHENYL-HYDRAZIDO-ACETIC ACID

C, 17, NH. WH. CH, .. CO, H. (159°). Formed by reducing the pheny hydrazide of glyoxylic acid (Elbers, A. 227, 353). Formed also by reducing phenyl-osotriazole carboxylic acid with sodiumamalgam (Pechmann, A. 262, 288). Hexagonal tables, sol. hot water. Re-oxidised by Fehling's tables, sol. hot water. Re-oxid solution to NHPh.N:CH.CO₂H.

u-Phenyl-hydgazido-acetic acid

NH2. NPh.CH2.CO H. [131°]. Got by saponifying its ether [127°], which is formed by heating phosyl nydrazine with chloro-acetic ether at 100° (Reissert a. Kayser, B. 24, 1519). Needles.

PHENYL-HYDRAZIDO-BUTYRIC ACID C₁₀H₁₄N₂O₂ i.e. CHEt(N₂H₂Ph).CO₂H. Formed by reducing the phenyl-hydrazide of ethyl-glyoxylic acid (Japp a. Klingemann, A. 247, 217). Needles (from McOII). Softens at 165%.

Phenyl-hydrazido-isobutyric acid

CMe₂(N₂H₂Ph).CO₂H.

Anhydride N.HPh CO. [175°]. Got by gently heating the nitrile with H.SO, and pouring into water (Reissert, B. 17, 1458). Crystals, v. sol. alcohol. -B'HCl: crystals.

Nitrile CMe2(N2H2Ph).CN. [70°]. Got by heating the cyanhydrin of acctone with phenyl-

With pients with p of the nitrile. B"H3Cl3: crystals.

Phenyl-hydrazido-butyric acid

NH.,.NPh.CHMe.CH,.CO.H. [1110]. Formed phenylfrom potassium \$B-bromo-butyrate, hydrazine and NaOAc in aqueous solution (Lederer, J. pr. [2] 45, 87). Plates (from alcohol), v. sol. hot Aq. Converted by conc. H₂SO₄ into oxy-phenyl-methyl-pyrazole dihydride.

PHENYL - B - HYDRAZIDO - CROTONIC ETHER CH3.C(NH.NHPh):CH.CO2Et. [50°]. Formed from acctoacetic ether (1 mol.) dissolved in other by adding phenyl-hydrazine (Nef. A. 266, 70; cf. Knorr, A. 238, 147). Colourless needles, v. e. sol. ether, sl. sol. ligroin. Turns yellow in air. Split up by conc. HClAq into phenyl-hydrazine and acetoacetic ether. When heated in vacuo at 200° it changes to oxy-phenylmethyl-pyrazole. Conc. H.SO, followed, after 10 minutes, by water forms methyl indole carboxylic ether [134°]. HgO oxidises it to the azo-compound CH, C(N₂Ph):CH.CO₂Et crystallising from light petroleum in red needles [51°]. AcCl forms a di-acetyl derivative CH, C(NAc.NAcPh): CH.CO Et (245°-250° at

150 mm.). PHENYL-HYDRAZIDO-METHYL-QUINOL-

INE C.H.MeN(N.H.Ph). [197°]. Formed from

(Py. 3) methyl-quinoline and phenyl-hydrazine (Ephraim, B. 24, 2820).

PHENYL - HYDRAZIDO - METHYL - THIAZOLE. Dihydride C₁₀II₁₂N₃S i.e.
CHMe.S
C.NH.NHPh. Phenyl-propylene-ψthio-semicarbazide. [93°]. Formed by heating
phenyl-allyl-thio-usea with cone. HClAq at 100°
(Arenarius, B. 24, 269). Yellowish plates (from
ligroin).—B'HCl. [202°]. Concentric crystals.
—Picratte. [167°].

PHENYL-HYDRAZIDO-PHENYL-ACETIC ACID C_{1.}H_{1.}N_.O₂ i.e. NHPh.NH.CHPh.CO.H. [158°]. Got by reducing the phenyl-hydrazide of phenyl-glyoxylic acid (Elbers, A. 227, 315). Crystalline, v. sl. sol. cold water, v. sol. alcohol.

PHENYL-HYDRAZIDO-PROPIONIC ACID C.H., N.O., **.c. NH., NPh. CHM.6.CO., II. [187]. Formed by boiling its amide with NaOHAq (Reissert, B. 17, 1454; 20, 3110; 22, 2021). The ether is got by heating lactic ether with phenyl-hydrazine. Needles. *Yields phenyl-a-amido-propionic acid on reduction.

Ethyl ether ELA. [116].—EtA'HCl. Nitrile. [58]. Formed by heating • CH,CH(OH).CN with phenyl-hydrazine at 100°. Amids. [124]. White crystals.

Phenyl-hydrazido-propionic acid
NHPh.NH.CHIMo.CO₂H. [172°]. Formed by
reducing the phenyl-hydrazide of pyruvic acid
with sodium-annalgam (Pischer a. Jourdan, B.
16, 2244; Japp a. Klingemann, B. 20, 3281; A.
247, 211). Needles (from MeOII). Re-oxidised by
cold Pehling's solution to NHPh.N:CMc.CO₂II.

PHENYL-HYDRAZIDO-QUINOLINE
C,H,N.NII.NHPh. [191°]. Formed from (Py. 3)chloro-quinoline and phenyl-hydrazine (Ephraim,
B. 24, 2818). Needles, v. sol. chloroform. Reduced
by HI and P to (Py. 3)-amido-quinoline.

PHENYL-HYDRAZINE C, H, N₂ i.e.
NHPh.NH₂. [23°]. (241.5° i.V.) at 750 mm.
S.G. 27 1097 (E. Fischer, A. 236, 198). H.C.v.
805,240. H.C.p. 806,300. H.F. 34,200 (from diamond) (Petit, A. Ch. [6] 17, 168).

Formation.—(E. Fischer, B. 8, 589, 1005, 1641; 9, 111, 880; A. 190, 67).—By the action of zine and HOAc on diazo-benzene anilide or diazo-benzene diethylamide.

Preparation.-1. A cold solution of 71 pts. of sodium nitrite in 50 pts. of water is slowly added to a well-cooled mixture of 10 pts. of aniline and 200 pts. of HCl (30 p.c.). To the diazo-benzene chlorido solution so prepared a cold solution of 45 pts. of stannous chloride in 45 pts. of HCl is now added, when the mixture immediately becomes a thick magma of phenylhydrazine hydrochloride, which is filtered off, basified, and distilled (Meyer a. Lecco, B. 16, 2976).—2. Aniline (28 g.) is dissolved in K.CQ. (21 g.) and water (500 c.c.) by passing in SO. The solution is mixed with a cold solution of NaNO₂ (25 g.) exactly neutralised by HOAc. After two hogrs the product is warmed till dissolved, acidified by HOAc, and reduced with zinc-dust and HClAq (Reychler, B. 20, 2463). By adding diazo-benzene nitrate to a cold aqueous solution of KHSO, heating the resulting C.H., N. SO.K with excess of KHSO., and de-composing the C.H., NH.NH.SO.K, thus formed, by heating with HClAq.

Properties.—Oil, solidifying to monoclinic tables; v. sl. sol. hot water, almost insol. KOHAq. Miscible with alcohol, ether, benzene, and CHCl. Volatile with steam. Reduces Fehling's solution in the cold, N, aniline, and benzene being formed. When heated for a long time at 150° it is gradually split up into aniline, NH_a, benzene, and N (Reissert a. Kayser, B. 23, 3703). Reduces ScO₂ to Se (Hinsberg, A. 260, 42). Gives benzene and N when boiled with CuSO₁. It is very poisonous. Reactions.—1. H₂O₂ forms benzene and diazo-

benzene imide PhN₃ (Wurgter, B. 20, 2633).— 2. Yellow HgO adued to its ethereal solution forms aniliue, N, and HgPh₂ (Fischer, 4, 199, 320). HgO added to a solution of the sulphate forms diazo-benzene sulphate and imide.— 3. SOCL in other forms in the cold NPhH.N:SO, which crystallises in yellow prisms [103]; v. sol. cther, volatile with steam. Thionyl-phenyl-hydrazine is hardly attacked by HCl, but is converted by NaOHAq into phenyl-hydrazine and Na. SO. Br forms NPhBr. NBr. AcCl forms diazo-benzene chloride, S, and HOAc (Michaelis, B. 22, 2228; A. 270, 115).-4. SO, passed into an ethereal solution of phenyl-hydrazine forms NHPh.NH.SO, as a crystalline pp. SO, passed into an alcoholic solution of phenyl hydrazine forms (NHPh.NHL) SO2; v. sol. water and alcohol, igsol, ether, crystallising in tables which shrink together at 70°, but decompose at a higher temperature (Michaelis a. Ruhl, B. 23, 474). SO₂ passed into a benzene solution at 75° forms NHPh.N:SO, which when heated with phenylhydrazine gives Ph.S., benzene, and N.--5. Dry CO, forms solid phenyl-hydrazine phenyl-carbazate (NHPh.NH.) CO. or N.PhH. CO.O.N.PhH, which is crystalline; sl. sol. water and ether, decomposed by hot water. - 6. CS, forms the corresponding N.PhH., CS.S.N.PhH, [97°], which at 110° splits up into H.S, and di-phenyl-thiocarbazide. COS forms crystalline COS(N.H.Ph). (Fischer, B. 22, 1935). -7. Zinc-dust and conc. HClAq slowly form aniline and NH3 -8. Excess of phenyl-hydrazine acts upon iodine, forming HI, aniline, and PhN₃ (Fischer, B. 10, 1335). Excess of I forms iodo-bonzene, N, and HI (E. von Meyer, J. pr. [2] 36, 115). This reaction may be used for the volumetric estimation of phenylhydrezine .- 9. Sulphur above 80° forms aniline. H.S. N. Ph.S., Ph.S. PhSH, benzene, and NH2-10. Nitrous acid forms PhN₃. KNO₂ added to the hydrochloride at 0° forms a yellow crystalline pp. of NPh(NO)NH .- 11. Alcoholic potash and chloroform form, on heating, $C_{14}H_{12}N_{*}$ [180°], mol. w. 236. This body crystallises in white needles; sol. alcohol, scarcely affected by HClAq at 200°, and yielding crystalline C, H,1N, NO 2 and C₁₁H₁₁N₁.SO₂H (Ruhemann a. Elliott, C. J. 53, 850)—12. EtBr forms NPhEt.NH₂, NPhH.NHEt, and NPhEt, Br. NH2.-13. Aqueous diazobenzene nitrate added to a cold solution of the hydrochloride ppts. PhN₃, aniline nitrate remaining in solution.—14. Reacts with aldehydes and ketones, forming phenyl-hydrazides; e.g. (Fischer, B. 17, 572) CH₂CHO+NPhH.NH.
- H₂O+CH₂CHN.NHPh. Thus a solution of phenyl-hydrazine hydrochloride (2 pts.) and crystallised sodium acetate (3 pts.) in water (20 pts.) gives a pp. of the phenyl-hydrazide when added to an aqueous solution of an aldchyde or ketone, either in the cold, or, in the case

of aromatic compounds, on warming. These phepyl-hydrazides are decomposed by acids into the original components, and, in alcoholic solution, by sodium-amalgam and HOAc into aniline and a base. The phenyl-hydrazides of ketones are converted by ZnCl₂ into derivatives of indole. The phenyl-hydrazides of aldehydes and ketones are described under the aldehydes, and ketones from which they are derived .- 15. Diketones containing the group CO.CHX.CO yield derivatives of phenyl-pyrazole. Saturated γ -liketones in ethereal solution usually form a mono- or di- phenyl-hydrazide; in HOAc the product is the anhydride of the mono-phenyl-hydrazide, a derivative either of CH.CH:N or of CH:CH-NN.NHPh (Klingemann, A. 265, 108) .- 16. Acetacctic ether forms a phenyl-hydrazide, which at 140° changes to oxyphenyl methyl-pyrazole TPh CO.CH. by loss of alcohol. Acetyl-propionic acid forms the com- occurs with benzoic, glyceric, and lactic acids. pound CH, C(N, HPh), CH, CH, CO, H [108]. Benzoylacetic ether forms two compounds [1320] and s[165°] (Bender, B. 21, 2495).—17. Leacts with sugars as with aldehydes; thus a solution of glucose gives CH (OII).(CH(OII)), CH:N_HPh [145"] on heating with phenyl-hydrazine, while galactose gives C₆H₁₂O₅(N_.HPh) [158] (Fischer, B. 20, 824). On heating these compounds with aqueous phenyl-hydrazine acetate at 100° 'osazones' are formed, e.g. phenyl-glucosazone CH,OH.(CH.OH), C(N HPh).CH:N, HPh [204] and the isomeric phenyl-galactosazone [c. 191"]. 18. By heating with phenyl-hydrazine hydrochloride and NaOAc arabinose is converted into C₁, H₂₀N₄O₃ [158°; formose into C₁, H₂₂N₄O₄ [·. 144°]; acrose (the product of the action of NaOHAq on glyceric aldehyde) into C_{ls}H₂N₁O₁ [c. 217°] and an isometade [159°2...-19. Phenyl [c. 217°] and an isomewde [159°].—19. Phenyl hydrazine acetato reacts with the product of oxidation of glycerin with Na CO, Aq and Br forming glycerosazone $C_{i_1}H_{i_2}N_iO$ crystallising from benzene in yellow plates [131°] (Fischer a. Tafel, B. 20, 1089, 3386). 20. Erythrite, after oxidation by dilute HNO, yields with phenylhydrazine hydrochloride and NaOAc the compound C₁H₆O₂(N.HPh)₂ [167°]. 21: Mannite on oxidation with HNO₃ yields levulose (mannitose) and mannose, which with phenyl-hydrazine forms $C_1H_1N_2O_2$ [195°-200°] (Fischer, B. 21, 1805).—22. The acetate reacts with the preduct of oxidation of dulcite by bromine and Na CO Aq with formation of the 'phenyldulciteosazone' $C_{18}H_{22}N_4O_4$ [206]. -23. Isodulcite heated with phenyl-hydrazine hydrochloride and sodium acetate at 100° forms 'phenyl-isodulcite-osazone' $C_{1a}H_{22}N_4O_4$ or $C_6H_{16}O_4(N,HPh)_2$ [180°]. Solutions of isodulcite and phenyl-hydrazine form, on mixing, C,H,,2O,(N,HPh)[150°] (Fischer a. Tafel, B. 20, 2574; Raymann, Bl. [2] 47, 760).—24. Sorbin heated with aqueous phenyl-hydrazine hydrochloride and NaOAc at 100° forms the osazone C, H,N,O, [164].—25. Milk sugar heated with aqueous phenyl-hydrazine flydro-chloride and NoOAc forms C,H,N,O, [200] and C₂₁H₂₀N₁O₅ [224°].—26. Mallose forms C₂₁H₂₂N₁O₅ [191°].—27. The acetate gives with glyorylic, fhenyl-glyoxylic, and pyruvic acids the corresponding phenyl-hydrazides [137°], [153°], and [192°] respectively.—28. Phenyl-

hydrazine in HOAc (50 p.c.) gives with a dilute solution of gluconic, galactonic, and arabinose carboxylic acids compounds C₈H₁O₈N₂H₂Ph [200°], [203°], and [216°] respectively (Fischer a. Passmore, B. 22, 2760). These compounds are m. sol. hot water. Saccharic acid gives a similar compound CaH11OsN2H2Ph [165'] which, as well as the compounds from mucic and metasaccharic acid, is almost insoluble. The compound from nucle acid melts at 240°. All these compounds contain the group CO.NH.NHPh. Compounds containing this group are also obtained by the action of phenyl-hydrazine and dilute HOAc at 100° on formic, succinic, malic, tartaric, Cinnamic, and callic acids, but not from glycollic, lacta, and glyceric acids. The compounds got from precinic, malic, gallic, and tartaric acid melt at 218, 223, 187, and 240 respectively. Acetyl-phonyl-hydrazine is produced when aqueous phenyl-hydrazine acetate is heated at 130°; and a similar reaction Compounds containing the group CO.NH.NHPh give a reddish-violet colouration with H2SO4 and a Iftle FeCl, and they are readily decomposed by KOHAq and by baryta into phenyl-hy-drazine and a salt of the acid (Fischer, B. 22, 2728). - 29. Glucose carborylic lactome yields C, H₁₃O, N₂H₂Ph [172°], while mannose carboxylic acid gives an isomeric body [223°].- 30. The acetate gives with rhamnose carboxylic acid the compound CallarOaNaHaPh [c. 210°], while \$1. Maionic acid heated at 100' with phenylhydrazine and dilute HOAc forms $C_{13}I_{43}N_1O_2$ [143°] and $CO_2H.CH_2.CO.N_2H_2Ph$ [154°], which when heated with water and phenyl-hydrazine at 200° yields $\text{CH}_2 < \frac{\text{CO}}{\text{CO}} > \text{N}_2 \text{HPh} \quad [128^\circ]. - 32.$ Lactic other forms, on heating, phenyl-hydrazido-propionic ether. a-Oxy-butyric acid at ido-propionic ether. a -Ory-bulpric acid at 160° forms $C_{11}H_{11}N_{1}O_{2}$ [152°], while mandelic acid $^{\bullet}$ yields $C_{11}H_{11}N_{1}O_{2}$ [182°] (Reissert a. Kayser, B. 22, 2924). -33. γ -Oxy-valeric dectone at 100° forms $C_{2}H_{10}O_{1}N_{2}P_{11}H_{1}$ [79°] (Wislicenus, B. 20, 402). -34. Benzoyl-carbinel gives N₁HPh₁CPh₁CH₂OH [112°] osazone N.HPh:CPh.CH:N.HPh aubmann, A. 243, 244). and the 243, [192] (Laubmann, A. 243, 244). — 35. Boiling aqueous itaconic acid forms the acid NHPh.N CH. CH. CH. CO. CH. [194°] (Scharfenberger, A. 254, 150) .- 36. Cinnamic acid forms C13H14N2O [183], which on distillation yields C15H12N2O[251] (Knorr, B. 20, 1107). -37. Acrolein reacts forming phenyl-pyrazole dihydride NPh< N:CH [52] (274") (Fischer a. Knoevenagel, A. 239, 194) .- 38. Mesityl oxide yields NPh CMe, CH, phenyl-tri-methyl-pyrazole (F. a. K.) .- 39. Chloro-acetone in alcoholic solution at -18° fo ans $C_{24}H_{23}N_{6}$ [158°] which yields an acetyl derivative $C_{24}H_{25}AcN_{8}$ [220°] (Bender, H. 21, 2496). s-Tetra-chloro-ecctons forms C_{1,H1,N}, [126°] converted by fuming HNO₃ into C_{1,H1,N}, 0, [235°] and by SnCl₂ to two bases C_{1,H1,N}, [77°] and [193°] (Levy a. Witte, A. 252, 343; Zincke a. Kegel, B. 22, 1478).—40. Tetrabromo-di-benzyl-ketone heated with alcoholic phenyl-hydrazine at 150° forms C,Ph₂(N,Ph), [70°] (Bourcart, B. 22, 1369).—41. Di. bronw-acete

crystallising from alcohol in yellow prisms (B.). 420 Bromo-acetyl-propionic ether mixed with an alcoholic solution of phenyl-hydrazine forms OH, C(N,4HPh).CH.CH.O.Et [117.5°], which on reduction with tin and HCl forms methyl-indole carboxylic acid (Bender). Bromo-acetyl-propionic acid forms. CH., C(N., IIPh). CH.CH.CO., H. 157° (Decker, B. 21, 2937). — 43. Di-chloromaleic imide at 100° forms C₄O₂(N₂H₂Ph)₂NH crystallising from acetone in orange-red needles (Giamician, B. 22, 2495).—44. Amides react thus: N₂H₂Ph + R.CO.NH₂ = NH₂ + R.CO.N.H.Ph (Just, B. 19, 1201).—45. Carbanic ether forms, (3018), B. 13, 1201).—45. Caroanuc etter forms, on heating, di-phenyl-carbazide CO((H.N.HP!h)₂ [151°] (Skinner a. Ruhemann, B. 20, 3372).—46. Reduces alloxan to allexantin, N and benzene being formed (Pellizzari, G. 17, 254). In this reaction the first product is the compound CO NH.CO C(OH). N., H., Ph (Skinner a. Ruhemann, C. J. 53, 550) .- 47. Perabanic acid with phenyl-hydrazine hydrochloride and NaOAc yields C₁₆H₂₀N₆O, [170°], which on boiling with water forms NH₂CO.NH.CO.CO.N₂H₂[1 [215°] (S. a. K.).—48. Urca heated with phenylhydrazine hydrochloride at 160° forms phenylurazole NPh

CO.NH [263°]. — 49. Reduces nitroso-aniline to p-phenylene-diamine and $C_{12}H_{12}N_1O$ (Fischer, B. 21, 2610). 50. The acetate (2 mols.) acting on nitroso-dimethylaniline (3 mols.) forms $C_{11}H_{16}N_1O$ [103°]. An ethereal solution of phenyl-hydrazine converts nitroso-di-methyl-anilino into di-methyl-amidobenzene-azo-di-methyl-aniline and phenylenebenzene-azo-di-metnyi-antine and pnenyiene-di-methyl-diamine. In alcoholic solution there is formed NHPh.C., II., NMe., [130°] which yields a nitrosamine C₁₄H₁₅N₂O [116°] (O. Fischer, B. 21, 2609).—51. Di-nitroso-acctone (1 mol.) mixed with phenyl-hydrazine (1 mol.) in hot alcoholic control of the c solution forms CH(NOH).C(N.HPh).CH(NOH) [145°]. Di-nitroso-acetone boiled with excess of phenyl-hydrazine acetate forms C15H12N4 or phenyi-nyarazine acctate forms $C_{13}H_{12}N_4$ crystallising in yellow plates $[122^2]_- = 52$. Diazoacetic ether at 100° gives off N and forms a colourless compound $[136^\circ]_- = 53$. p-Diazobenzene sulpkonic acid forms the compound · N3C6H4.803NaH4Phaq crystallising in plates (Griess, B. 20, 1528). -54. Di-acetyl-succinic ether fused with phenyl-hydrazine at 100° forms CO₂Et.CH(CMe:N₂PhH).CHAc.CO₂Et [91°] and CO₂Et.CH(CMe:N₂PhH).CO_Et which on heating with toluene at 180° gives diwhich on neating with tollene at 100° gives all coxy-di-phenyl-di-methyl-dipyrazyl (q.v.). — 55. Dioxims form additive compounds; c.g. glyoxim yiolds C,H_(NOH),N,H,Ph [110°]. di-phenyl-glyoxim yields C,Ph_(NOH),N,H,Ph [150°], while the di-oxim of (β)-naphthoquinone forms C₁₀H₆(NOH),N,H,Ph [138°] (Polonowsky, B. 21, 182).—56. Phloroglucin kept for five days with an alcoholic solution of phenyl-hydroxine in the an alcoholic solution of phenyl-hydrazine in the cold forms C_cH₁(OH)(N_cH_.Ph), [144°] which may be oxidised by FeCl, to C_cH₁(OH)(N_.Ph), [177°] (Baeyer B. 22, 2891).—57. Thio-acetoacetic ether forms S(CH CO-NPh) 1 Modern etner with CMe; N) 2 [183°], together with the compounds NHPh.N:C CMe:N 8,(CH<CO -NPh). and di-oxy-di-phenyl-di-

phenone forms N. HPh: CPh.CH: N. HPh [148°],

methyl-dipyrazyl (Sprague, C. J. 59, 332).—5i
Cyanogen passed into an emulsion of phenyinydrazine in cold water forms the dicyanide (infra).—50. Cyanogen passed into an alcoholi solution forms PhN.H. C(NH).C(NH).N.PhH [225°], crystallising in white plates (from alcohol). The same compound is formed by the action of phenyl-hydrazine on cyananiline. I gives a rose-red colour with calcoholic NH. Cone. H.So.; is coloured indigo-blue. Dry HC forms the hydrochloride C., H., N., 2HCl [188°]. Drute HCl forms PhN.NH.CO.C(NH).NHNHP! [180°].—60. Cyananiline in chloroform sclution forms, after boiling, matted needles of the compound C2, H2, N.Cl. [200°-212°]. This body is perhaps (PhH.N., CHCl.C., H1, 18, 2HCl (Senf. J. pr. [2] 35, 533).—61. PCl., in ether form amorphous NHIB.N.P.NH.NHPle converted by water into (NHPh.NH).POH, a yellowish-white powder [92°] which reduces Fehling's solution in the cold (Michaelis a. Oster, A. 270, 126). This body is split up by acids into phenyl-hylazine and H.PC., oasily decomposed by acids and alkalis (Michaelis, A. 270, 135).—63. PSCl., forms, in like manner, PS(NH.NHPh), [154°].—64. AsCl., forms, (N.PhH.), BCL., o. 65. BCl., forms, in like manner, (N.PhH.), BCL., v. sol. water, decomposed at 242°.—66. C.H., PCl., in ether forms NHPh.N.PC.H., [152°] crystallising from EtOAc in plates (Michaelis, 2. co., E. BCl., forms, in like manner, (N.PhH.), BCL., v. sol. water, decomposed at 242°.—66. C.H., PCl., in ether forms NHPh.N.PC.H., [152°] crystallising from EtOAc in plates (Michaelis a. Oster, A. 270, 129). It reduces hot Fehling's solution, and is split up by acids into PhPO_H2, and phenyl-hydrazine.

Salts.—B'HCl. Plates, m. sol. water. Got by ppg. an alcoholic solution of the base by HCl, and washing the pp. till it is colourless.—B'HBr. Needles (from water).—B'_HSO. Plates, v. sol. water.—B'C.H.M.O. Yellow needles.—B'_HLGO. Plates.—Benzene sulphinate; [131] (Escales, B. 18, 895).—Dinitro-(a)-naphthol sulphonate: lighthrown needles, sl. sol. hot water (Richardson, C. N. 58, 39).—Sulphocyanide: sparingly soluble plates. Changes at 160°-170° into phebyl-thio-semicarbazide.—B'H,PO. [118°] (Michaelis, A. 270, 127, 133).—B'_HPO. [121°].—B'C.H.PHO. [135°]

B'C_H_PH_O__ [135°].

Sodium derivative C_H_NNa.NH_ Formed by dissolving 8g. of sodium in 70g. of warm phenyl-hydrazine. The H evolved reduces some of the phenyl-hydrazine to NH, and aniline when the reaction is complete the aniline and excess of phenyl-hydrazine are distilled off by heating the product in an oil-bath to 200° 210° (not higher) in a current of H. It is a yellow hygroscopic powder. When finely divided it sometimes takes fire in the air. Decomposed by water into phenyl-hydrazine and NaOH. Readily reacts with alkyl haloids, giving unsymmetrical phenyl-alkyl-hydrazines (Michaelis, B. 19, 2448; A. 252, 266).

Formyl derivative NHPh.NH.CHO. [145°]. Formed by heating formamide with phenyl-hydrazine at 180°. White scales.

Acetyl derivative NHPh.NHAc. [1284].
Formed by heating phenyl-hydrazine with MOAc
or acetamide (Fischer, A. 190, 129; Just. B.

19, 1201). Formed also from the sodium-derivative and Ac.O at 0° (Michaelis a. Schmidt, A. 252, 3017. Six-sided prisms, sl. sol. cold water.

١.

Di-acetyl derivative NPhAc.NHAc. [108°]. Formed from NPhNa,NH, and AcCl in ether. Tables or needles, v. e. sol. alcohol. Completely reduces hot Fehling's solution.

Chloro-acetyl derivative NHPh.NH.CO.CH,Cl. [115°]. Formed from the base and CH.Cl.COCl in ether (Gattermanu, B. 25, 1081).

Propionyl derivative NHPh.NH.CO.Et. 6158°] (Freund a. Goldschmidt, B. 21, 2161).

n-Butyryl derivative. [114°]. Scales, v. sol. ether (Michaelis a. Schmidt, A. 252, 308).

Isovaleryl derivative NHPh.NH.CO.CH.Pr. [101°]. Formed from the base and accto-valeric anhydride (Auten-Formed from

rieth, B. 20, 3190). Plates, v. sl. sol. cold ligroin. Hexoyl derivative [117°]. Needles.

s-Benzoul derivative [169°]. Formed from phenyl-hydrazine by adding BzCl in ether at 0° (Fischer, A. 190, 125), or by heating with benzamide (Just, B. 19, 1203). Formed also by warming phenyl-hydrazine with BzCy (Hausknecht, B. 22, 329). Prisms, sl. sol. hot water. Yields NPhMe.NHBz on methylation. Reduces HgO. Phthalic anhydride at 180° forms an addition-compound $C_{21}H_{10}N_{2}O_{1}$ [1722], crystallising from alcohol in prisms. It is probably $CO_{2}H.C_{0}H_{1}.CO.NPh.NIBz$. At 250° it splits up into benzoic acid and (3)-phthalyl-

 $\textbf{phenyl-hydrazine} \ C_{_{0}}H_{_{4}};C_{_{2}}O_{_{2}} \diagdown \Big| \\ NPh$

NPhBz.NH. u-Benzoyl derivative [70°]. A product of the action of BzCl in benz-[70°]. A product of the action of B251 in action on NPhNa.NII, at 0° (Michaelis a. Schmidt, B. 20, 23, 1718; A 252, 310). Needles (from water). Reduces hot Fehling's solution but not HgO. Conc. HCl at 150° gives HOBz and phenyl-hydrazina. HNO, forms in acid solution benzanilide and N.O. but in neutral solution it forms N₃Ph and HOBz. Reacts like phenylhydrazine with aldehydes and ketones; thus acetone yields NPhBz.N:CMe₂ [115^{-5°}], aceto-phenone forms NPhBz.N:CMePh [124°], and benzoic aldehyde gives NPhBz.N:CHPh [122°]. Salts.—BHCl. [202°]. Needles, m. sol. HClAq. water.—B'HNO, [145°].—B'C₆H₁N₅O, [122°]. Needles, sl. sol. cold water.—B'₂H₂SO, [191°]. Needles, sl. sol. cold water.—B'HNO, [145°].—B'C₆H₁N₅O, [122°]. Di-benzoyl derivative NPhBz.NHBz.

[178°] (Fischer, A. 190, 128; M. a. S.). Prisms, v. sl. sol. water, sol. alkalis. On methylation it yields NPhBz.NHBz.—NPhBz.NBzNa: plates.

Benzoyl - acetyl derivative NPhBz.NHAc. [153°]. Got from NPhBz.NH, and Ac.O. Needles (from dilute alcohol).

p-Nitro-benzoyl derivative NHPh.NH.COC, H., NO2. [198]. Formed from phenyl-hydrazine and C,H,(NO2)CN (Haus-knecht, B. 22, 328). Yellowish-red needles.

o-Amido-benzoyl derivative. [170°]. Got by warming phenyl-hydrazine with an alcoholic solution of isatoic acid (Meyer, J. pr. [2] 83, 20). Yellow needles, v. sl. sol. other.

n Amido-benzoyl derivative NHPh.NH.CO.C.H., NHA [151°]. Formed by

heating phenyl-hydrazine (1 mol.) with m-amidobenzoic acid (1 mol.) at 165° (Pellizzari, G. 16, 200). Scales, insol. cold alkalis, sol. acids.

Amido-toluyl derivative [3:6:1] C.H.Mc(NH.).CO.N.H.Ph., [198°]. Formed from methyl-isatoic acid and phenyl-hydrazine (Panactovitch J. pr. [2] 33, 68). Prisms (from chloroform), sl. sol. ether.

Phenyl-acetyl derivative N2H2Ph.CO.CH2Ph. [169°]. Got by heating phenyl-scetic acid with phenyl-hydenzine at 150° (Bülow, A. 236, 196). Needles (from alcohol), sl. sol. water.

Cinnamoul derivative N.H.Ph.COC.H.Ph. [258°). Got by Heating cinnamic acid with phenyl-hydrazine at 190° (Knorr, B. 20, 1708). Forms, on distillation, a compound C₁H₁₂N₂O [258°], crystallising in needles with green fluorescence.

Of alyl derivative C.O. (N.H.Ph), [278°]. Described in vol. iii. p. 655.

Ethyl-malodyl derivative

CHEt(CO.N.H.Ph). [233°]. Got by heating ethyl-malonic amide with phenyl-hydrazine at 220° (Freund a. Goldsmith, B.21, 1242). Needles (from HOAc). Converted by COCl, into C₁₉H₁₆N₄O₄ [113°].

Succinyl derivative C,H,:C,O,:(N,H,Ph), [218°]. Formed from succinyl chloride (1 mol.) and phenyl-hydrazine (2 mols.). Formed also by heating C2H4:C2O2:S with phenyl-hydrazine and HOAc (Zanetti, Rend. Accad. Linc. [4] 5, i. 225). Plates (from HOAc) (Freund, B. 21, 2456; Fischer a. Passmore, B. 22, 2734). When succinic anhydride is heated with phenyl-hydrazine at 160° there is formed C₂H₄:C₂O₂:N.NHPh [155°], which yields a nitrosamine C₂H₄:C₂O₂:N₂Ph.NO [84°] (Hötte, J. pr. [2] 35, 293).

(a) - Phthalyl derivative C.H. C.O.: N.NHPh. [179°]. Formed from phenylhydrazine and phthalyl chloride in ether (Pickel, A. 232, 233). Formed also by heating phenylhydrazine (1 mol.) with phthalimide (1 mol.) at 120° (Pellizzari, G. 16, 203; Just, B. 19, 1204); or with phthalic anhydride (1 mol.) at 150° (Hötte, J. pr. [2] 33, 99; 35, 268). Prepared by boiling an alcoholic solution of phthalic anhydride with phenyl-hydrazine. Colourless needles (from alcohol), insol. water and alkalis. Conc. H₂SO₂ forms a violet solution, turning brown. Reactions.—1. Converted by boiling alcoholic potash into N.H₂Ph.CO.C₂H₄.CO₂H₄ [166°], an acid of which the benzoyl derivative acid of which the benzoyl derivative NHPh.NBz.CO.C.H.,CO.H [172°] is formed by heating NHPh.NHBz with phthalic anhydride at 180°.—2. Boiling aqueous KOH or HClAq at 150° splits it up into phthalic anhydride and phenylhydrazine. —3. Benzoyl chloride at 160° forms C.H.;C.O.;N.NPhBz [193°].—4. Nitrous acid passed into its solution in diluted HOAc forms the nitramine CoH,:C2O2:N.NPh.NO2 [148°]; but in boiling HOAc it forms the di-nitro-derivative C, H, N, O, [182°]. Nitrous acid passed into phthalyl-phenyl-hydrazine suspended in ether forms the nitrosamine C₄H₁:(2O₂:N.NPh(NO) [154°].—5. Alcoholio NH₄ at 80° forms unstable NH₂CO.C₆H₄:CO.NH.NHPh [146°], which decomposes at 170° into NH₃ and (β)-phthalyl-phonyl bytessize (212°) phenyl-hydrazine [210°].

(B) - Phthalyl derivative

 $C_2H_4:C_2O_2 < NH_1$. [210°]. Formed at the same time as the (a) isomeride by heating phenylhydrazine with phthalimide or phthalic anhydride, being the chief product when the temperature is above 163° (Pellizzari, G. 16, 204; 17, 278; Hötte, J. pr. [2] 35, 284). Monoclinic tables (from benzene) or prisms (from alcohol), sol. alkalis. Ammoniacal AgNO. ppts. C.H.:C.O.N.PhAg.

Reactions. - 1. NaOMe and MeI at 100° form C₆H₄(C₂O₂:N₂PhMe [125°], which is decomposed by cone. HClAq into phthalic acid and NHPh.NHMe. 2. KOEt and Ett give C₆H₄O₂:N₂PhEt [106°].—3. BzCl at 200° forms C₆H₄O₂:N₂PhAe [122°].

Phthulyl derivative C,H4(CO.NH.NHPh)2. [191°]. Formed by heating phenyl-hydrazine (2 nols,) with hithalic anhydride (1 nol.) at 150° (H.). White tables. At 170° it gives the (β)-phthalyl deri vative [210°].

Nitrosamine NH, NPh.NO. Formed by adding NaNO, to an aqueous solution of plenylhydrazine hydrochloride at 0° (Fischer, A. 190. 92). Pale-yellow plates. Very poisonous. Converted by hot alcoholic potash into diazobenzene-Alcoholic HCl acts in like manner. Exhibits Liebermann's reaction.

Dicyanide C_xH_xN₄ i.e. NH_x,NPh.C(NII).CN? Separates as colourless flakes when evanogen is passed into an emulsion of phenyl-hydrazine and cold water (Bladin, B. 18, 1544). Monoclinic lamine, v. sol. alcohol and ether. Decomposes above 160°. Yields a formyl derivative C,H,(CHO)N, [193].

Reactions. -1. By heating with Ac₂O it is converted into C₁₀II₈N₄ [108], which on saponification yields an acid C₁₀H₉N₃O₂ [177°], which on heating loses CO2, leaving oily CaHaNO3 (c. 240°).—2. By heating with propionic anhydride it is converted into $C_1H_{10}N_4$ [38'].—3. By treatment with nitrous acid, followed by boiling with water, it yields C.H.N., crystallising in needles [56°], v. sl. sol. water .- 4. Acetic aldehyde in alcohol and HCl give CH3.CH:N.NPh.C(NH).CN • [96.5°], crystallising in pale-yellow plates, v. e. sol. alcohol and ether, insol. water; converted by alcoholic AgNO, into phenyl-methyl-triazole carboxylic nitrile [109] (Bladin, B. 25, 184) .--5. Benzoic aldehyde forms the corresponding CHPh:NNPh.C(NH).CN [129:5°], crystallising from alcohol in prisms, oxidised by FeCl, to C₁₆H₁₀N₄ [166°] (Bladin, B. 22, 796).—6. Pyrawic acid in alcohol forms the above phenyl-methyl-triazole carboxylic nitrile on warming gently (Bladin, B. 19, 2598).—7. Boiling acetoacetic ether forms the compound CO₂H.CH₂CMe:N.NPh.C(NH).CN [209°], the oily ether of this acid, and phenyl-methyl-triazole carboxylic nitrile N NPh.C.CN [109°] (Bladin, B. 25, 190). The acid forms the salts KA' and NH, A', and is converted by nitrous acid CO.H.C(NOH).CMe:N.NPh.C(NH).CN into [218°], [218°], and by potash into the compound CO.H.CH.CMe:N.NPh.CO.CN [188°], from CO.H.CH. CMe:N.NPh.CO.CN [188°], from which potassium nitrite and HClAq form CO.H.C(NOH).CMe:N.NPh.CO.CN [209°].

References .- AMIDO-, LODD-, NITRO-, and OXT PHENYL-HYDRAZINE.

u-Di-phenyl-hydrazine NPh₂.NH₂. [34·5°] (220° at 40 mm.) (Stahel, A. 258, 243). Formed by reducing di-phenyl-nitrosamine NPh, NO ir alcoholic solution with zinc-dast and HOAc (E Fischer, A. 190, 174). Monoclinic tables (from ligroin), partially decomposed on distillation into diphenylamine and NH, Conc. H.SO forms a deep-blue solution. Decomposed by nitfous acid into NPh, NO and N.O. Reduces HgO, forming in the cold crystalline tetra-phenyl-tetrazone, NPh., N:N.NPh. [123°], but if the temperature rises the products are N and diphenylamine. Benzoic aldehyde forms NPh.N:CHPh [122°]. With salicylic aldehyde, furfuraldehyde, glucose, mannose, galactose, and rhamnose it forms di-phenyl-hydrazides, melting at 139°, 90°, c. 162°, c. 155°, 157°, and 134° respectively.
Salts. B'HCl. Needles, v. sl. sol. cold water.

-B'2H2SO; needles, m. sol. dilute H2SO;

Formylderivative NPh. NH.CHO. [116:5°]. Formed by boiling the formyl deriva-tive of phenyl-hydrazine with ammoniacal CuSO₄ (Gattermann, B. 25, 1075). Needles, sl. sol. hot water and ligroin, v. sol. alcohol.

Acctul derivative NPh., NHAc. Formed by boiling NIIPh.NHAc with HOAc and Cu(OAc), (Tafel, B. 25, 413).

Propionyl derivative. [178]. Needles. Benzoyl derivative NPh2.NHBz. [189°] (G.); [192] (Fischer, A. 190, 178). Needles (from acctone), m. sol. alcohol,

Phthalyl derivative C,H,O,:N.NPh... [155°]. Formed by heating di-phenyl-hydrazine with phthalic anhydride at 160° (Hötte, J. pr. [2] 35, 271).

s-Di-phenyl-hydrazine NHPh.NHPh. drazo-benzene. Mol. w. 184. [131°]. H.C. 1,598,000 (from diamond) (Petit, M. Ch. [6] 17, 163). S. (alcohol) 5 at 16° (Moltschanowsky, C. J. 42, 965). Prepared by passing H₂S into a solution of azobenzene Ph.N_x.Ph in alcoholic NH₃ (Hofmann, Pr. 12, 576). Formed also by reducing nitro-benzene with sodium-amalgam or zinc-dust (Alexejeff, Z. 1868, 497; Glaser, A. 142, 364). Laminæ, sl. sol. water, m. sol. alcohol and ether. Yields aniline and azobenzene on distillation.

Reactions .- 1. HClAq converts it into the isomericdi-p-amido-diphenyl (benzidine). H.SO. acts in like manner. 2. Readily oxidised to azobenzene, even by moist air .- 3. Nitrous acid. passed into an alcoholic solution at 0°, yields a nitroso- compound which, when warmed, Violently decomposes into NO and azobenzene (Bacyer, B. 2, 683).—4. On heating with BzCl it yields di-benzoyl-di-p-amido-diphenyl; formic acid gives di-formyl-di-p-amido-diphenyl (Stern, B. 17, 379); and phthalic anhydride yields diphthalyl di-amido-diphenyl (Bandrowski, B. 17, 1181).—5. Boiling benzoic aldehidle forms azobenzene, but benzoic aldehyde and ZnCl2 gives C1.H2(N:CHPh), (Clève, Bl. [2] 45, 188). Benzoic aldehyde, heated with hydrazobenzene at 120°-

150°, forms' benzhydrazoin' CHPh NPh [55°]. The o-nitro- derivative C.H. (NO2).CHN2Ph2 of this body melts at 66°.—8. Furfuraldehyde forms C₄H₃O.CH
NPh [59°] (Cornelius a. Homolka, B. 19, 2240).—7. Phenyl cyanate (2 mols.) and some benzene at 150° forms the compound NHPh.CO.NPh.NPh.CO.NHPh [220] (Goldschmidt a. Rosell, B. 239490).

Acetyl derivative NHPh.NPhAc. [159°]. Formed from s-di-phenyl-hydrazine and Ac.O in the cold (Stern, B. 17, 330). Needles (from alcohol). Decomposed by heat into acetanilide

and azobenzene.

Di-acetyl demivative NPhAc.NPhAc. [105°]. Formed from s-di-phenyl-hydrazine and Ac.O (Schmidt a. Schultz, B. 12, 485; A. 207, 326). Yellowish trimetric crystals (from alcohol); a:b:c = 67:1:56, not affected by dilute HClAq.

Chlofo-derivatives C_aH₃NH.NHC_aH₄Cl. [90°].—N_aH₄(C_aH₄Cl[1:3]). [91°].—N_H(C_aH₄Cl[1:4])₂ [122°] [Claus a. Heu-

(Janowsky a. Erb, B. 20, 361). Tables. Con-Verted by H SO, into bromo-benzidine.

Di-bromo- derivatives N.H. (C. H.Br.). o. [82°]. m. [109°]. p. [130°] (J. a. E.; Gabriql, B. 9, 1406; Werigo, A. 165, 192).

Iodo · derivatives v. vol. iii. p. 41. Nitro-derivatives v. vol. iii, p. 607.

Oxy-derivatives v. vol. iii. p. 743. Chloro-nitro- derivative

NHPh.NHC_H_C(NO.) [1:3:6]. [135°-140°]. Formed from chloro-di-nitro-benzene and phenyl-hydrazine in alcohol (Willgerodt a. Ferko, J. pr. [2] 37, 355). Red prisms.

p-Amido-derivative. The compound NHPhNHLC₆H₁,NHAe [146²] is got by treating C.H.,N.,C.,H.,NHAe with alcoholic ammonium sulphide (Schultz, B. 17, 463). Yellowish plates (from dilute alcohol). Re-oxidised to the azo- compound by air.

Di-m-antido- derivative

N₂H₂(C₆H₄.NH₂)₂, [141°] (Gebe**b**, A. 251, 193). Got by treatment of m-nitro-aniline with alcoholic potash and zinc-dust (Craeff, A. 229, 311), or with sodium-amalgam (Haarhaus, A. 135, 164). Golden needles (from alcohol). Yields $C_{12}H_3Br_3N_4$ [150°] and $C_{12}H_12Ac_2N_1$ [247'].— $B''H_2Cl_2...=B''H_2PtCl_6...=B''2HNO_1...=B''H_1SO_1...=$ B"H,C,O, Prisms, v. sl. sol. water.

Di-y-amido-derivative. [115]. Got by reducing N₂(C₆H₄,NO₂)₂ with alcoholic ammonium sulphide (Gerhardt a. Laurent, A. 75, 7. Lermontoff, B. 5, 232). Yellow crystals. Yields quinone on oxidation. — B"H₂Cl₂.
B"2HNO₂.

Di-diphenyl-hydrazine v. Hydrazo-diphenyl. PHENYL-HYDRAZINE o-CARBOXYLIC ACID C,H,NO2 i.e. NH2.NH.C,H,CO2H. Hydrazido-benzoic acid. Formed from o-amidobenzoic acid by diazotising and treating the product with Na₂SO, (E. Fischer, B. 13, 670; A. 212, 333). Needles, sol. hot water. Reduces Fehling's solution in the cold. -- HA'HCl: needles, sol. hot water.

heating the acid at 220°. Monoclinic plates (from alcohol); a:b:c = 0.072:1: .064; $\beta = 75^{\circ} 18'$.

Sublimes in white needles. -- NaC, H, N,O xaq: silvery plates. — B'HCl: white needles. — B'HgCl: needles (from water). Yields an acetyl derivative C.H.Ac.N.O [112°].

Phenyl-hydrazine m-carboxylic acid

N.H.*C.H.,CO.H. [186°]. Formed by the action of tin and HClAq on C.H.(CO.H).N:N.SO.K, which is got by warming the nitrate of m-diazobenzoic acid with aqueous K2SO, (Griess, B. 9, 1657; Roder, A. 236, 164). Plates, sl. sol. hot Aq.

Reactions. -1. Acetone forms $G_{so}H_{12}N_2O_2$ [150], which gives EtA' [91°]. -2. Benzow addehyde forms CHPh: N.NH.C.H .. CO.H [172°] .-3. Pyruvic acid reacts with formation of CO_H.CMq.N.NH.C, H₁CO₂H [208°], which forms whetstone shaped crystals (containing aq), and gives EtA' [102°] .- 4. Glucose, heated with the fives Eth. [103].—4. trucose, neutod with the hydrochloride and MaOAe, gives C₂₀H₂₂N_Q, [208].—5. Phenyl-thicorbinide forms the compand C₁₁H₁₁N₃SO₂ [205°].

Salts.—14A'HCl.—BaA₂' 4aq. Nodales.

Phenyl-hydrazine p-carboxylic acid
Bromo derivative C₆H₃,NH.NH.C₆H₄Br. N₂H₄,C₆H₄,CO₅H. [220²-225²]. Formed, in the
benzene and alcoholic approximation same way as its isomeridae from the control of the control (from water). -HA'HCl : sl. sol. cold water.

s-Di-phenyl-hydrazine di-o-carboxylic acid 1H₁₂N₂O₁ i.e. CO₂H₁C₃H₁NH₂NH₃NH₄CO₂H₅CO₂H₅O₁. w. 272. [205°]. Formed by reducing Mol. w. 272. [205°]. Formed by reducing o-azoxy-benzoic acid with sedium-amalgam (Griess, B. 7, 1609; Homolka, B. 17, 1904). Small colourless plates. Oxidised by moist air to o azobenzoic acid.

s-Di-phenyl-hydrazine di-m-carboxylic acid, Hydrazo-benzoic acid. Formed by boiling m-azobenzoic acid with FeSO, and NaOHAq (Strecker, A. 129, 141). Insol. water, sl. sol. hot alcohol. In alkaline solutions it absorbs O, being oxidised to azobenzoic acid. Boiling conc. HGAq forms azobenzoic acid and amidobenzoic acid. Yields orange-red crystals of BaA". On warming with SnC and HClAq at 100° it yields di-amido-diphenyl dicarboxylic acid and two other acids. One of these $C_{11}H_{10}N_{2}O_{3}$ crystallises from hot water in yellowish needles and forms BaA' 77aq and HA'HCl. The other acid C14H12N2O1 crystallises in yellow needles melting above 290°, and forms NaA'4aq, BaA', 2aq, HA'HCl, HA'HBr, and (HA'), H., SO, (Kusseroff, B. 23, 913).

s-Di-phenyl-hydrazine di-p-carboxylic acid C_1,H_1,D_1,O_1 . Formed by boiling p-azobenzoic acid with FeSO, and NaOHAq (Reichenbach a. Beilstein, A. 132, 137; Billfinger, A. 135, 152). Formed by boiling p-azobenzoic Needles (from alcohol), easily oxidised in alkaline solution.

s-Di-phenyl hydrazine tetra-carboxylic acid [1:4:2]C₆H₃(CO₂H)₂.NH.NII.C₆H₃(CO₂H)₂ [2:1:4]. Formed by reducing azoxytorephthalic acid in alkaline solution with sodium-amalgam (Homolka

a. Löw, B. 19, 1092). White crystalline pp., v. sol. alcohol and ether.

PHENYL-HYDRAZINE m-SULPHONIC ACID C₆H₄(N₂H₅),SO₂H. Formed from m-amido-benzene sulphonic acid by diagotisation and subsequent reduction by SnCl₂ at 0° (Limpricht, B. 21, 3409). Crystals (containing 2aq), sl. sol. cold water, nearly insol. alcohol. Converted in alcoholic solution by nitrous acid into

 $N_sC_sH_sSO_sH_s$ Phenyl-hydrazine p-sulphonic acid [1:4]O,H,(N,H,).SO,H.

Formation.—1. From diazobenzene p-sulphonic acid by warming with aqueous K.SO, followed by HOI (E. Fischer, A. 190, 74).—2. By heating phenyl hydrazine sulphate with ClSO, H at 160° (Limpricht, B. 18, 2196).—3. Together with alcohol, by heating phenyl-hydrazine ethyl-sulphate at 160°.—4. By heating phenyl-hydraz-ine (1 pt.) with H₂SO₂ (6 pts.) at 100° (Gallinek a. Richter, B. 18, 3172).

Properties.—Needles (containing aq), sl. sol. water. By boiling with CuSO, it is neatly oxidised to N and benzene sulphonic acid. With acetoacetic ether and dilute (50 p. c.) HOAc at 155° it forms CMe CH. CO. (Möllenhoff, B. 25, 1849), which crystallises with aq.

Salts. - NaA' 1 aq. - NH, A' - BaA', 5aq. -

PbA', 2aq. — ZnA', 4aq: minute tables.

Phenyl-hydrazine v-sulphonic acid. Potassium salt. C.H.NH.NH.SO.K. Formed from stum satt. C_aH₃NH.NH.SO₂M. Formed from diazobenzene nitrate and K₂SO₃ (180mer, Z. 1871, 481) and also by heating pheavi-hydrazine with K₂S₂O₇ (Fischer, A. 190, 97). Crystals (containing aq), sl. sol. cold water and alcohol. Oxidised by HgO to CaHs. No. SOaK. Split up by boiling HClAq into phenyl-hydrazine and KHSO.

Phenyl-hydrazine disulphonic acid NH₂.NH₂C₂H₃(SO₃H)₂. Two acids of this formula are got by further sulphonation of the mand p- sulphonic acids respectively (L.). They both yield BaA" and BaH₂A"₂.

s-Di-phenyl-hydrazine m-sulphonic acid C_eH₂.NH.NH.C_eH₄.SO₂H. Formed by heating the disulphonic acid with water at 200° for 3 days (Limpricht, B. 11, 1048). Yellow needles (containing 2 aq). - KA' 4aq. - PbA', 3aq. BaA', 4aq: yellow plates, v. sol. water. Chloride C₁₂H₁₁N₂SO₂Cl. [240°]. Di-bromo-derivative

C.H.Br.NH.NH.C.H.Br.SO.JI. Formed as a by-product in the exidation of C.H.Br.(NII.)SO.JH 1:3:6:4] by KMnO, (Limpricht, B. 18, 1425).-KA' aq: long needles.

s-Di-phenyl-hydrazife di-m-sulphonic acid N₂H₄(O₂H₄;SO₂H)₂. S. 079 at 22°. Formed by reduction of nitro-, azo-, or azoxy-benzene-sulphonic acid (Limpricht, B. 11, 1048; 21, 3409; 23, 1057; Bruhnemann, A. 202, 344; Mahrenholz a. Gilbert, A. 202, 337; Neumann, B. 21, 8419). White needles, v. e. sol. water, almost insol. alcohol and other. Readily reduces ammoniacal AgNO, and Fehling's solution. Readily reduces HClAq immediately forms benzidine disulphonic

Amide NH(C₆H₄SO₂NH₂).NH.C₆H₄SO₂NH₃. [248]. Formed by reducing N₁(C₆H₁S₀,NH₂), with zine-dust and NH₂Aq or HOAc (Limpricht a. F. Meyer, A. 268, 132). White needles (from 50 p.c. acetic acid), almost insol. water, ether, and toluene. Reduces ammoniacal AgNO, forming a mirror. HClAq converts it into the amide of diamido-diphenyl (benzidine) disulphonic acid, m-amido benzene sulphonic amide and N₂(C₆H₄,SO₂NH₃)₂, — N₂H₄(C₆H₄,SO₂NHK)₂ I₂³aq. Thin needles or plates quickly oxidised by air.— N₂H₄(C₆H₄,SO₂NHNa)₂ 2 aq: needles.

s-Di-phenyl-hydrazine di-p-sulphonic acid N.H.₁(C.H.,SO.H). Obtained, in the same way as the preceding acid, from amido-benzene p-sulphonic acid.—BaH.A".—BaA": crystalline. Isomeride.—V. BENZIDINE TETRASULPHONIC ACID, vol. i. p. 174.

DI . PHENYL . HYDRAZINE v. DI . THIO . CARBOXYLIC ACID NPh., NH.CS.SH. [c. 109°], Formed by dissolving NPh., NH, in CS. (Stabel, A. 258, 249). Golden prisms, v. sol. alcohol, insol. water.

s-Di-phenyl-hydrazine di-m-thiosulphonic acid N₂H₂(C₆H₄,SO₂SH)₂. Formed, together with N₂(C₆H₄,SO₂SH)₂, by adding N₂(C₆H₄,SO₂Cl)₂ to a cold saturated solution of Ba(SH)2 (Limpricht, pp., becoming steky on boiling with water. Oxidised by KMnO₄ to N₂(C₈H₄,SO₄H)₂.—BAA'' 2aq: minute needles, sl. sol. cold water. TRI - PHENYL - HYDRAZOÏN is Benz-

hydrazoin, v. s-DI-PHENYL-HYDRAZINE, Reaction 5. DI. PHEN YL. HYDROQUINONE C. H. 10.2 i.e. C. H., Ph. (OH). [5:2:4:1]. [219°]. Formed by reducing di-phenyl-quinone with aqueous SO. (Müller a. Pechmann, d3. 22, 2131). Colourless cubes (from dilute alcohol).

PHENYL-IMESATIN v. ISATIN. PHENYL-IMIDO-DIACETIC ACID

NPh(CH₂CO₂H)₂. [150°-155°]. A product of the action of aniline on chloro-acetic acid (P. Meyer, B. 14, 1325; Hausdörfer, B. 22, 1796). Formed also by heating phenyl-amido-acetic agid with chloro-acetic acid and NaOAcat 120°-130° (H.). Needles, v. sol. hot water and alcohol. NPhH A'. Needles (from alcohol). Decomposes at 151°.

Mono-anilide

CO2H.CH2NPh.CH2.CO.NHPh. [213°]. Formed together with the dianilide by heating the acid with aniline at 175°. Needles. Its ether CO.Et.CH. NPh.CH. CO.NHPh [122°] is got by heating the anilide of phenyl-amido-acetic acid (q.v.) with other and NaOAc at 140°.

Di-anilide NPh(GH, CO, NHPh)₂. [218°]. Needles, v. sl. sol. alcohol.

TRI - PHENYL - TRI - IMIDO - BENZENE $\mathbf{C}_2,\mathbf{H}_2,\mathbf{N}_3$ i.g. $\mathbf{C}_a\mathbf{H}$ (NHPh)₃. [242°]. Formed by warming $\mathbf{C}_a\mathbf{H}_a\mathbf{C}\mathbf{I}_a$ with aniling (Mohr. M. 11, 22). Golden plates, v. sol. chloroform, insol. water and alcohol. Conc. $\mathbf{H}_a\mathbf{SO}_a$ gives a dark-blue

colour changed to violet by potash.

PHENYL - IMIDO - BENZYL - MALONIC ETHER C.H.C(NPh).CII(CO.Et).. [75°]. Formed, together with (C.H., C(NPh)).C(CO.Et)., by the action of sodium malonic ether on the compound C, H, CCl:NPh (Just, B. 18, 2624). Decomposes at 150° into alcohol and oxyphenyl-quinoline carboxylic ether.

DI-PHENYL IMIDO-DI-ETHYL DISTIL. PHONE NH(CH, SO, C, H), [78]. Got by heating C, H, (SO, C, H, J, with NH, Aq is seaked tubes (Otto, J. pr. [2] 30, 324). Triclinic plates (from alcohol).—Nitrate: [190°].—B'HCl. [193°].— B'.H.,PtCl.; plates, sl. sol. water. PHENYL - IMIDO - METHENYL - 0 - AMIDO-

C_eH₄< NH C:NPh. (c. 230°). PHENOL

Formed by heating $C_eH_4 < {}^{\rm NH}_O > C\delta$ with aniline at 210° (Von Chelmicki, J., pr. [2] 42, 440). Needles, insol. water, sl. sol. cold alcohol. DI-PHENYL-DI-IMIDO-NAPHTHOL v. (β).

NAPHTHOQUINONE, Reaction 5. PHENYL-IMIDO-DINAPHTHYL v. PRENTL DINAPHTHYLENE AMINE.

PHREVIANIDO PHENYL METHYL THI . ZOLE . DIHYDRIDE NPh C(NPh).S

138°]. Formed from di-phenyl-thio-ures and hloro-acetone (Traumann, A. 249, 51). Yelwish prisms, insol. water, v. sol. ether. DI . PHENYL - DI - IMIDO - DI - PHENYL -

LAZTHIOLE TETRAHYDRIDE CaHan,S i.e. C(NPh).NPh . [131°]. Got by oxidising dihenyl-thio-ures with H.O. (Hector, B. 23, 357).
PHENYL-IMIDO ROPIONIC ACID

[123°] H. C(NPh).CO.H. Anilpyrthic acid. by the principle of the property of the proper

Isomeridee, Intro-PHENTI, PROFICIOI ACID.
PHENYI, IMIDO-SUCCINIC ACID
O.H.CH., C(NPh), CO.H. [150°]. Formed by
te action of dilute (1 p.e.) KMnO, on 'pyranilyroic' acid (Anschütz, B. 22, 738; cf. Reissert,

21, 1942). Decomposed on fusion.
PHENYL-IMIDO-THIAZOLE DIHYDRIDE

(NPh) < NH.CH. [124°]. Formed from

H2Cl.OHCl.OEt and phenyl-thio-urea (Näf, A. 55, 125). White needles, sol. alcohol. Yields nitrosamine C₀H₇(NO)N₂S [58°].

Di-phenyl-imido-thiazole dihydride

(NPh) S - CH [105°]. Formed from dichloro-di-ethyl oxide and di-phenyl-thio-urea.

DIPHENYLINE v. DI-AMIDO-DIPHENYL. PHENYL-INDAZINE C, H10N2 i.e.

 $C_dH_4 < \frac{N}{CH} > NPh.$ [84°]. (345° uncor.). Formed by reducing o-nitro-benzyl-aniline with tin and HClAq (Paal, B. 23, 2640; 24, 961). Needles (from scohol). Not affected by distillation over red-hot zinc-dust. Itedweed to a dinydride [98°] by adding Na to its alcoholic solution. Yields a methylo-iodide B'MeI [188°].

PHENYL INDOLE C.H. CH NPh CH. (327° i.V.). Formed by heating its earboxylic acid [176°] (Fischer a. Hess, B. 17, 567; Pfülf, A. 239, 221). Oil, v. sol. alcohol. Its solution in HClAq colours pine-wood intensely violet.

Phenyl-indole C.H. CH SCPh.

phenanthridine. [186°]. (above 360°).

Formation.—1. By boiling w-bromo-acetophenone or phenyl-wamido-acetophenone with aniline (Möhlau, B. 14, 173; 15, 2480; 18, 165). 2. By heating the phenyl-hydrazide of aceto-phenone or of phenyl-acetic aldehyde with ZnCl, at 180° (Fischer, B. 19, 1565; 21, 1071; A. 236, 135).—3. By passing benzylidene-o-toluidino through a red-hot tube (Etard, Bl. [2] 39, 531). 4. By the action of zinc-dust and NH,Aq on C.H.(NO₂).CH₂.CO.C.H₃.(Pictet, B. 19, 1065). Properties. Colourless plates, insol. water.

May be sublimed. Colours pine-wood violet-blue. Yields B'C.H.N.O. [127°]. Nitrous acid forms a nitroso-derivative $C_uH_4 < \frac{C(NO)}{NH} > CPh$ [c. 258°], which yields B'HCl, B'HNO, and NaC, H,N.O, and may be reduced to amidophenyl-indole [174°].

Dahydride CuHush. [46°]. Formed by Vor. 17.

boiling phenyl-indole with zinc-dust, alcohol, and HCl. Colours pine-wood orange. Yields a nitrosamine.

с.н.<СРһ>он. Phenyl-indole Formed by the action of alcoholic HCl on the phenyl-hydrazide of phenyl acetic aldehyde (Fischer, B. 21, 1811). White plates (from ligroin), v. sol. alcohol. Converted by heating for fifteen minutes with ZnCl, into the preceding isomeride [186°]. Yields a picrate [107°] and a nitrosamine C.H. CPh CH [61°] which gives Liebermann's reaction (Ince, A. 253, 87).

Di-phenyl-indole C.H. CPh CPh. [123°]. Formed by heating the phenyl-hydrazide of de-oxybenzoin with ZnCl₂ (Fischer, B. 14, 1566; A. 236, 136). Colourless crystals, v. sol. alcohol. Does not give the pine-wood reaction. Its picrate crystallises in dark-red needles.

Di-phenyl-indob CaH4 < CH > CPh. (above 360°). Got by heating the u-di-phenyl-hydrazide of acetorhenone with ZnCl, at 175° (Pfülf, A. 239, 223). Oil. Colours acidified pine-wood bluish-violet.

PHENYL-INDOLE CARBOXYLIC ACID

 $C_{13}H_{11}NO_2$ i.e. $C_6H_4 < \frac{C(CO_2H)}{N(C_6H_3)} > CH$. Formed by heating the di-phenyl-hydrazide of pyruvic acid with HOAc and HClAq (E. Fischer, H. 17, 567). Needles, v. sl. sol. water, v. sol. alcohol. NaOCl in the cold forms phenyl ψisatin C,H, CO CO. [134°] (Pfülf, A. 239, 222).

PHENYL INDOXAZINE C.H. CH N. [84°]. Got from o-bromo-benzophenone and an alkaline solution of phenyl-hydrazine (Catheart a. V. Meyer, B. 25, 1498). Large crystals. PHENYL-INDULINE C₂,H₁₇N₂ i.e.

ÇH:CH----Ç:N C(NPh).CH:C.NPh C.H., [231°]. Mol. w. (by C(NF)-CHICAPP Raoult's method) 320-370 (calc. 347). Formed from amido-phenyl-induline [152°] by treatment with nitrous acid (Fischer a. Hepp. A. 262, 257; 266, 263). Reddish tables, with blue reflex; v. sol. benzene, insol. ligroin. Heated with HOAc (5 pts.) and HCIAq (25 pts. of 20 p.e.) at 165° for six hours it forms: (a) C₂₁H₁₈N₁O crystallising from benzene in steel-blus plates [218°], forming a brownish-red solution in HClAq, and converted by cone. HClAq at 200° into a compound $C_{10}H_{14}N_2O_2$; (b) the compound $C_{10}H_{14}N_2O_2$ [c. 280°] which crystallises from benzene or alcohol in brownish-yellow prisms or plates, and is both base and phenol. Its hydrochloride crystallises from conc. HClAq in prisms with green lustre; (c) benzolindone $C_{18}H_{12}N_2O$; (d) a body which dissolve in benzene with fiery brown fluorescence, and is perhaps carbazole-fluor-indine (Fischer a. Hepp, A. 266, 249). Benzolindone C₁₅H₁₂N₂O i.e.

CH:CH.C:N CO.CH:C.NPh Co.H. Formed by heating phenyl-induline with HOAc and HClAq at 160°-200° (Fischer a. Hepp, A. 266, 253). Lustrous brown plates, insol. alkalis, sol. dilute HClAq, forming a rose-coloured solution. Its solution in conc. H.SO, is green. Yields phenazine on distillation with zinc-dust.

PHENYL IODIDE v. IODOBENZENE PHENYL IODOMETHYL SULPHONE

C.H., SO. CH.I. [64-52]. Formed from benzene aulphinic acid, NaOEt, and CH.I. at 100° (Michael a. Palmer, Am. 6, 253). Prisms (from alcohol). NaOEt at 75° gives phenyl-methyl sulphone and products of oxidation (Otto, B. 21,

PHENYL-ITACONIC ACID CHPh:C(CO.H).CH. CO.H. [1729]. Formed by the action of Na or NaOEt on phenyl-paraconic acid (Fittig, A. 256, 68). Prisms, sl. sol. cold acid (Fittig, A. 250, 68). Prisms, 81. sol. cold water. Yields phenyl-isocrotonic acid [1799] and 7-0xy-phenyl-futyric lactone [379] when boiled with diluted H.SO. (1:1). Br gives bromophenyl-paraconic acid 6, H.BrO. [999] and arm isomeride [1449].—BAA" 23aq.—CaA".—Ag.A".

Ethyl ether Et.A". (315° uncor.). Oil.
Di-PHENYL-KETONE V. BENGOPHENONE.

Di-phenyl diketone v. Benzil.

Di-phenyl triketone C.H., CO.CO.CO.C.H., [70°]. (248° at 40 mm.). Formed by distilling CBz_Br.OAo in vacuo. Formed also by adding aqueous NaNO, to a solution of the mone oxim in HOAc, and boiling (Pechmann, B. 22, 852; 23, 3375). Hygroscopic golden needles (from ligroin, v. sol. all solvents. Give a blue colour with H2SO, and benzene that contains thiophene.

Reactions .-- 1. Alkalis decompose it, forming benzoin, benzoic acid, and CBzPh(OH).CO2H [118°].—2. Phenyl-hydrazine forms a phonyl-hydrazide C₂₁H₁₆N₂O₂ [c. 135°], benzene-azo-triphenyl-pyrazole C₈H₃.N₂.C≪CPh.NPh CPh:N and a third compound [223°] .-- 3. Aniline gives rise to Compound [225].—5. Antime gives rise to CPh(NPh).C(OH). COPh [100°] and C(OH). (CPh:NPh). [148°].

Hydrate Bz.C(OH). [90°].

Mono-oxim Bz.C:NOH. [146°]. Formed

from Bz,CH, and nitrous acid. Tri-oxim (C.H. C(NOH)), C:NOH. [186°]. Formed from the triketone and hydroxylamine.

Di-phenyl tetraketone C.H. CO.CO.CO.CO.C.H_a. The hydrate [88°] of this body is formed by the action of conc. HNO, on phenyl-glyoxal (Abenius a. Söderbaum, B. 24, 8084).

DI-PHENYL-KETONE CARBOXYLIC ACID v. Benzoyl-benzoic acid.

Di-phenyl ketone dicarboxylic acid v. Benzo-

PHENONE DICARBOXYLIC ACID. Di-phenyl diketone o-carboxylic acid

C.H. CO.CO.C.H. CO.H. Formed by oxidising deoxybenzoin o-carboxylic acid with alkaline KMnO, (Graebe, B. 21, 2003; 23, 1344). Occurs in a yellow modification [141.5°] and a white variety [125°-130°]. The yellow modification is nearly twice as sol. alcohol and chloroform as the white variety, and is converted into the white variety by dissolving in alkali and ppn. by soids. The white modification changes into the yellow one at 115°-125°.

Dicarboxylic acid v. DIPHTHALYLIC ACID. DI-PHENYL-KETOXIM v. Oxim of Benzo-PHENONE

PHENYLLACTIC ACID v. OXY-PHENYL-PRO-PIONIC ACID.

PHENYL-LACTIMIDE v. vol. i. p. 180.

PHENYL-LUTIDINE-CARBOXYLIC ACID & PHENYL-DI-METHYL-PYRIDINE-CARBOXYLIC ACID.

PHENYL-LUTIDONE v. Oxy-phenyl-di-METHYL-PYRIDINE.

PHENYL-MALEIC ACID C, H,O, i.e. CO.H.CPh:CH.CO.H. Formed by dissolving its anhydride in water and extracting with ether (Alexander, A. 258, 77). Prisms, m. sol. water. Begins to lose water below 100°

Anhydride CH .CO O. [119.5°]. Formed by distilling phenyl-malic scid. Needles, insol.

water, v. sol. chlosoform and ether. Di-phenyl-maleïc acid CO2H.CPh:CPh.CO2H. Stilbene dicarboxylic acid. Formed by saponification of its nitrile. Its ether is formed, neation of its nitrie. Its eather is formed, together with di-phenyl-fumaric ether, by the action of Na on a-bromo-phenyl-aceta ether in ether (Reimer, B. 14, 1800; Rügheimer, B. 15, 1626). The free acid splits up at once, on liberation from its splits, into H₂O and anhydrida On distillation with limit in the life. dride. On distillation with lime it yields s-diphenylethylenc.—K₄A": needles, v. sol. water.

—Ag₂A": amorphous pp.—Ag₁A'A, needles,

Ethyl ether Et₂A". [54°]. Prisms,

Linide C₁₀H₁₀O₂(NH). [218°]. Needles,

almost insol. water, v. sol. alcohol.

Phenylimide' C, H10 O2 (NPh). [175°]. Formed by heating the anhydride with aniline at 120° (Anschütz a. Bendix, A. 259, 63).

Nitrile CN.CPh.CPh.CN. Dicyanostilbene. [158°]. Formed by heating a bromo-phenylacetonitrile alone or with alcoholic KCy (Reimer, B. 14, 1798). Plates (from benzene).

Isonitrile. [2420]. Occurs in small quantity in the preparation of the nitrile by heating the product of bromination of phenylacetonitrile. Golden needles (from alcohol). Yields an acid [222°] on saponification.

Anhydride CPh.CO O. [155°].6 (236° at 15 mm.). Formed by adding HCl to solutions of salts of the acid, or by heating di-phenylfumaric acid at 260° (Reimer, B. 13, 742). Trimetric needles (from dilute alcohol), abic = 693:1: 385, insol. water, sol. CS. May be sublimed. Its alkaline solution reduces AgNO. Not changed by NaOHAq into the fumaroid form (Delisle, A. 269, 91). NaOHAq (15 p.c.) at 100 forms a polymeride melting much above 250°, insol. water and other solvents.

Reactions.—1. Reduced in alcoholic solution by zinc-dust and HCl to a mixture of the two diby 2h0-dust and 11c4 to a unxure of the two appenyl-succinic acids.—2. Fuming HNO, gives rise to an amorphous di-nitro derivative (C_aH₄(NO₂))_C(O_a -3. p-Tolyl-acetic acid forms C₁Ph_O₂:CH_C(H, [165°], crystallising in yellow coding at Phone and Castic acid and No. needles .- 4. Phenyl-acetic acid and NaOAc at 225? form CPh.C(CHPh) O [176°], which may be reduced by HI and P to benzyl-di-phenyl. maleïde CPh.CH(CH,Ph) O [128°] (Gabriel a. Cohn, B. 24, 3228, 3854). The compound Cohn, B. 24, 3228, 3854). The compound C,Ph,O₂(CHPh) combines with Br, forming C,Ph,BrO₃(CHPh) [154°], which splits up at 155°-160° into HBr and C,Ph,O₂(CBrPh) [165°]. The compound C,Ph,HO₂(CH,Ph) is converted by potash into CO,H,C,Ph,CH(OH),CH,Ph [174°], and by an alcoholic solution of NEIH, into CO(NHEt).C,Ph,CH(OH).CH,Ph [196°]. The

compound C₄Ph₂O₄(CHPh) is converted by KOH to Me₄C(SO₄Ph), [97°]. — 6. Chloro - acetoms at C₄Ph₂O₄(OH).CH₂Ph [185°], and in benzene reacts on PhSNa in ether, forming acetonylication by HNO₂ into C₄Ph₂O₄(OH).CH(NO₂)Ph phenyl-sulphide PhS.CH₂CO.CH₄ [35°] (209°) [125°] (which yields an acetyl derivative [166°]), and the compound C₂Ph₂O₄(NO₄).CH(NO₂)Ph crystallises in prisms, 8l. sol. hot water, v. sol. 146°], which is converted by boiling sloohol into O,Ph,O,c(NO,)Ph [177°], a body that may be reduced by HI and P to iso-benzyl-diphenylmaleide [118°]. Benzyl-di-phenyl-maleide is sonverted by alcoholic NH, at 180° into CPh.CH(CH,Ph) NH [170°], which yields a

pitrosamine [136°].

PHENYL-MALIC ACID v. Oxy-PHENYL-SUC-DINIC ACID.

PHENYL-MALONAMIC ACID v. MALONIC

DI-PHENYL - MALONIC ACID. Ethyl sther of the nitrile CPh₂(CN).CO₂Et. [50°]. Formed from CPh₂Cl.CO₂Et and HgCy, at 125° (Bickel, B. 22, 1537). Yellowish tables.

Reference.—Di-nitro-phenyl-malonic ethen.
PHENYL-MANDELIC ACID v. Phenyl derivative of Mandelic acid.

PHENYL MELAMINE v. vol. ii. p. 322.
PHENYL MERCAPTAN C.H.SH. Thio-

plenol. Phenyl-sulphydrate. Mol. w. 110. (168°) (L.); (172°) (F. a. C.). S.G. 2 1-078. Formation.—1. A product of the dry distillation of sodium benzene sulphonate (Kekulé, Z. 1867 194; Stenhouse, A. 149, 248; Pr. 17, 62). 2. Together with Ph. S and diphenylene sulphide by heating benzene with S and AlCl, at 75° (Friedel a. Crafts, C. R. 86, 884; A. Ch. [6] 14, 1371.—3. By distilling phenol (10 mols.) with P₂S₃ (1 mol.), the yield being 6 p.c. of the phenol used (Kokulé, Z. [2] 3, 193, 306; Beckmann, J. pr. [2] 17, 456).—4. From Ph.S₂ and K.S in alcohol (Otto a. Rossing, B. 19, 3129).—5. By distilling C.H. SO, Na with NaSH (Stadler, B.

17, 2080). Preparation. - Phenyl ethyl dithiocarbonate, or a mixture of diazobenzene chloride solution and potassium ethyl dithiocarbonate (xanthate) is boiled with alcoholic potash until the solution remains clear on addition of water. The alco-hol is then distilled off and the residue dissolved in water, mixed with a little H.SO, and zinc-dust (to prevent oxidation), and distilled with steam. The distillate is extracted with ether. The yield is 75 p.c. of the theoretical (Leuckart, J. pr. [2] 41, 187).

Properties .- Oil, v. sol. alcohol and ether. Smells like garlic. Attacks the skin. Conc. H.SO, forms a violet solution, changing on warming through cherry-red to blue (Baumann, H. 5, 321; cf. Brunner, B. 4, 984).

Reactions .- 1. Readily oxidised to Ph. S. 2. CH,CCl, and dilute (20 p.c.) NaOHAq form CH,C(SPh), crystallising in white plates; v. sol. hot alcohol (Laves, B. 25, 353).—8. Acetoacetic ether and dry hydrochloric acid form CH, C(SPh), CHaCO, Et [58°], crystallising from alcohol in plates. Not attacked by boiling HClAq, atcohol in plates. Not attacked by colling invividual, but decomposed by alkalis into alcohol, PhSH, and CH_rC(SPh):CH.CO₂H [177°] (Escales a. Baumann, B. 19, \$790).—4. NH_rCOCl forms NH_rCO.NH.CO.SPh [218°] (Gattermann, A. 244, 43).—5. Actions and HCl in the cold give (Ma_rC(SPh)₂ [56°] (Baumann, B. 19, 2804), which is oxidised by KMnO₄ and H_rSO₄

alcohol; combines with KHSO, yields a phenylhydrazide [82.5°], and is converted by oxidation into Ph.SO₂.CH₂.CO.CH₃ [57°]. Acetonylphenyl sulphide may be converted by successive pnenyi sulphide may be converted by successive treatment with HCy, alcoholic hydrochloric acid, and alcoholic potash into the acid PhS.CH."CMc(6H).CO.H [97], which yields CaA'₂ aq, BaA'₂ aq, and AgA', and is oxidised by KMnO₄ to Ph.SO., CH., CMc(OH).CO.H [121].—7. Chiloral forms CCl., CH(OH)(SPh) [53°] decomposed by heat into its components (Baumann, B. 18. 888).—8. Combines with preguence acid. B. 18, 886).—8. Combines with pyruvic acid, ferming CH₂.C(OH)(SIA).CO₂H [87°], but in presence of gaseous HCl it forms the 'marcaptol' CH₃.C(§Ph), CO₂H [117°] which is not attacked by boiling HClA or alcoholic potash.—9. Phenylglyoxylic acid forms C,H,,C(OH)(SPh),CO,H converted by HCl gas into C,H,C(SPh),,CO,H [148°] (Escales a. Baumann, B. 19, 1789).—10. β-Acetylpropionic acid does not combine directly, but propionec acid does not combine directly, but in ptesence of hydrochloric acid it forms CH₂C(SPh)₂CH₂CH₂CQ₂H [69°], which is not attacked by alkalis, but is decomposed by dilute acids into PhSH and acetyl-propionic acid (E. a. B.).—11. CH₂CO.CH₂SPh forms CH₂C(SPh)₂CH₂SPh [55°], crystallising in cubes; v. sol. alcohol, insol. water; converted the acid that in [1] (C(Ph)₂CO) ph. (EL SO Ph. by oxidation in CH₃.C(SPh)(SO₂Ph).CH₂.SO₂Ph by oxidation in CH₂C(Srh)(SO₂Fh)-CH₂SO₂Ph [157°], crystallising in needles, sl. sol. cold alcohol, split up by alkalis into Ph.SO₂CH₃, PhSH, and Ph.SO₂H (Autenrieth, B. 2t, 170).—12. CBr₂(SO₂Et)₂ and NaOHAq form PhSCH(SO₂Et)₂ [86°), crystallising in tables; v. sl. sol. bot water v. sol. alkelia, corrected by v. sl. sol. hot water, v. sol. alkalis; converted by alcoholic NaOH and MeI into PhS.CMe(SO,Et), [113°], crystallising in white needles: m. sol. hot alcohol (Fromm, A. 253, 166; Laves, B. 25, 361). — 13. NaSPh reacts with isobutylene bromide, forming NaBr, Ph2S2, and isobutylene (Otto, B. 23, 1052)

Salts .- NaSPh. When Na is dissolved in an ethereal solution of PhSH containing phenol, a pp. of NaSPh is got while NaOPh remains in solution.—Hg(SPh),: colourless nædles (from alcohol).—ClHgSPh: plates.—Pb(SPh),: yellow crystalline pp., split up on distillation into PbS and Ph.S. Cu(SPh)2: pale-yellow powder.

AgSPh: pale-yellow crystalline pp.

Methyl ether PhSMe. (188°). Formed from Pb(SPh)2 and MeI (Obermeyer, B. 20,

Éthyl ether PhSEt. (204°) at 744 mm. Formed from NaSPh and EtI at 120° (Beckmann, J. pr. [2] 17, 457), and by the action of PhSH on PhN₂Cl (Stadler, B. 17, 2078). Liquid with unpleasant smell.

Allyl ether v. PHENYL ALLYL SULPHIDE. Acetyl derivative PhSAc. (229°). Formed from phenyl mercaptan and AcCl (Michler, A. 176, 177). Oil.

References. - AMIDO-, BROMO-, CHLORO-, CHLORO-NITRO-, NITRO-, and OXY- PHENYL-MERCAPTAN.

PHENYL-MERCAPTURIC ACID C, H, NSO, i.e. NHAc.CMe(SPh).CO2H. [143°]. by reducing bromo-phenyl-mercapturic scid with

sodium-amaigam (Baumarin, B. 15, 1732; 18, 258; H. 5, 835; 8, 190). Tetrahedra, m. sol. alcohol. Lesvorotatory in alcoholic solution. Solutions of its salts are dextrorotatory. Decomposed by dilute H.SO, into HOAc and phenylcystein.—BaA', 3aq; needles.

References.—Brown- and Chloro- Phenyl-

MERCAPTURIC ACID.

PHENYL-MESITYL-CARBINOL v. PHENYL-TRI-METHYL-PHENYL-CARRINGL.

PHENYL-MESITYL-CARBINOL CABBOXY-LIC .ANHYDRIDE v. TRI . METHYL - PHENYL-PHTHALIDE.

PHENYL MESITYL KETONE v. PHENYL TRI-LETHYL-PHENY; KETONE.

PHENYL-METHACRYLIC ACID v. PHENYL-CROTONIC ACID.

PHENYL-METHACRYLIC ALDEHYDE

CHPh:CMe.COH. (150° at 100 mm.). Formed by adding NaOHAq to a mixture of penzoic aldehyde and propionic aldehyde (Miller a. Kinkelin, B. 19, 525). Oil. Reduces ammoniacul AgNO₃. Combines with bisulphite. Yields a phenyl-hydrazide [137°].

PHENYL-METHANE v. Toluene. • Di-phenyl-methane C₁₃H₁₂ i.e. CH₂Ph₂. Mol.

w. 168. [25°]. (c. 263°).

Formation.—1. Together with C, H, (CH, Ph), by boiling benzyl chloride with benzene and zinc-dust (Zincke, B. 4, 298; C. J. 24, 508, 688).

2. By the action of H₂SO₄ and HOAc on a mixture of benzene and benzyl alcohol (Meyer a. Wurster, B. 6, 963) .- 3. By heating bentzophenone with zinc-dust (Staedel, B. 6, 1401; 7, 1480; cf. Barbier, C. R. 79, 812), or by reducing it with HI and P (Graebe, B. 7, 1624), or Zn it with H1 and F (Graebe, B. 7, 1024), or Zn and H₂SO₄ (Zincke, B. 10, 1473).—4. From benzene, CH₂Cl₂, and AlCl₃ (Friedel a. Crafts, Bl. [2] 41, 824; A. Ch. [6] 11, 264).—5. From CH. (OMe), benzene, HOAc, and H.SO. (Baeyer, B. 6, 221).—6. By distilling barium di-phenylacetate with soda-lime (Jena, A. 155, 86).

Preparation. - By adding AlCl, (35 g.) to a mixture of benzyl chloride (100 g.) and benzene (500 g.) (Friedel a. Crafts, A. Ch. [6] 1, 478; Bl.

[2] 33, 337).

Properties.—Prisms, v. sol. alcohol and other, smelling like oranges. According to Reissert (B. 23, 2242) it melts at 23°. Oxidised by chromic acid mixture to benzophenone. Yields diphenylene-methane when passed through a red-hot tube (Graebe, B.-7, 1623). Prolonged treatment with Cl in presence of I forms CCl, and C.Cl. (Ruoff, B. 9, 1048).

Tri-phenyl-methane Cl. H. i.e. CHPh. [92°].

(330°) (Schwarz); (355°) (K. a. F.).

Formation.—1. By heating PhCHCl₄ with HgPh, at 150° (Kekulé a. Franchimont, B. 5, 907).—2. By heating Ph₂CH(OH) with benzene and P₂O₄ at 155° (Hemilian, B. 7, 1203).—3. By heating (8)-benzpinacolin C₂₈H₂₆O with soda-lime at 300° (Thörner a. Zincke, B. 9, 65).—4. Together with a little CH₂Ph₂ by adding AlCl₂ to a mixtus of chloroform and benzene (Friedel a. Crafts, J. pr. [2] 16, 233; A. Ch. [6] 1, 496). 5. With other products, by the action of AlCl, on benzene mixed with CH,Cl, with CCl, with PhCCl, and with CPhHBr. (PhHBr (Magatti, B. 12, 1468; Schwarz, B. 14, 1526; Anschütz, A. 235, 208).—6. By heating benzoic aldehyde 729). Needles, v. sol. alcohol and ether. AAA.

(100 g.) with benzene (147g.) and ZnCl, (100 g.) at 260° for 7 hours (Griepentrog, B. 19, 1876; A. 242, 329).

Preparation.—AlCl₂ (500 g.) is slowly added to a mixture of benzene (1400 g.) and chloroform (400 g.). The mixture is finally heated on the water-bath, water is carefully added, and the oil dried and fractionally distilled. It is finally purified by conversion into the compound with benzene (Allen a. Kölliker, A. 227, 108; cf. Fischer, A. 194, 252; Schwarz, B. 14, 1516).

If the benzene contains toluene the product will contain a homologue (Hanriot, Bl. [3] 1, 773).

Properties. Plates (from alcohol), v. son benzene, ether, and CHCl, m. sol. cold alcohol. Crystallises from benzene in efflorescent rhombo-Crystallises from benzene in emorescent momor-hedra CHPh₂C_H, [76°]. Oxidised by chromic acid to tri-phenyl-carbinol [159°]» AlCl, at 120° decomposes it, but below 80° it forms CH₂Ph₂ (Friedel a Crafts, C. R. 200, 692). On exhaustive chlorination with SbCl, it yields CCl, and C, Cl, (Merz a. Weith, B. 16, 2876). Na has no action at 300°, but K at 200° forms a red substance (CKPh₂). K at 250° Torms a dark mass, whence HClAq liberates C₁₀H₁₄ [148·5°] (360°) (Hanriot a Saint-Pierre, C. R. 108° 1119; Bl. [3] 1, 774). The potassium derivative CKPha absorbs CO, at 200°, yielding CPh, CO,H [264°]. Benzyl chloride acting on CKPh, forms the compound CPh, CH, Ph [140°]. BzCl forms C₂₀H₁₀O [172°] which may be reduced by HI and P to C20H20 [234°].

References. — Amido-, Bromo-, Chloro-, Methyl-amido-, Nitro-, Nitro-amido-, Oxy-AMIDO-, and OXY- PHENYL-METHANE.

DI-PHENYL-METHANE DI-O-CARBOXY-LIC ACID CH₂(C₂H₄CO₂H)₂. [255°]. Formed by reducing the lactone of CH(OH)(C₂H₄CO₂H)₂. with HI and P (Graebe a. Juillard, A. 242, 253).
Crystals (from alcohol). Yields anthraquinone on heating at 280°.—BaA 6aq. S. 47.

Methyl ether Me₂A" [44°].

Isomeride v. BENZYL-ISOPHTHALIC ACID. Di-phenyl-methane tricarboxylic acid

Do-phenyl-methane transformed acid CO_H.CH(C,H,CO_H). [220°] S. 095 at 25°. Got by heating the lactone of the oxyacid CO_H.C(OH)(C,H,CO_H), with HI and P at 170° (Gracbe a. Juillard, A. 242, 235). Crystals (containing aqf. At 270° it forms a red compound C, H, O, [261°].

Methyl ether Me.A". [145°]. Tri-phenyl methane o-carboxylic acid CHPh, C, H, CO, II. [162°].

Formation.-1. By the action of NaOH an zinc-dust on di-phenyl-phthalide (Baeyer, B. 12 644; A. 202, 52).—2. By heating phenyl phthalide with benzene and AlCl, (Gresly, A 234, 242).—8. By saponifying the nitrile, which is obtained from CHCl₂.C.H₄.CN, benzene, and AlCl, (Drory, B. 24, 2572).

AlCi, (Drory, B. 24, 2572).

Properties.—Needles (from alcohol), insol water. May be sublimed. Yields tri-phenyl methane when heated with Ba(OH)₂. CrO_a in HOAc oxidises it to diphenyl-phthalide.

Nitrile CHPh₂C₂H₄.CN. [89°].

"Tri-phenyl-methane-p-carboxylis acid [162°]. Obtained by sandmeyer's reaction from earnide-tri-phenyl-methane [84°] (Fischer a samide-tri-phenyl-methane [84°] (Fischer a samid p-amido-tri-phenyl-methane [84°] (Fischer a Frankel, A. 241, 864; Otto a. Pischer, R. 24,

An isomeric acid melting above 360° was obained by Oppenheimer (B. 19, 2029) by oxidising he corresponding aldehyde with Ag.O.

Tri-phenyl-methane dicarboxylic soid CHPh.C.H.(CO.H), [1:2:5]. [280°]. Formed by reduction of the lacton of tri-phenyl-carbinol dicarboxylic acid by zinc-dust and NaOH (Hemilian, B. 16, 2375). Needles (from HOAc). Conc. H.SO, forms a greenish-yellow solution, which on heating changes through green, blue, and violet to purple.—BaA"4aq.—Ag₂A": pp.

Tri-phenyl-methans dicarboxylic acid CHPh.C.H.(CO.H.), [13:4]. [778°]. Formed by boiling di-phenyl-phthalide dicarboxylic acid with zinc-dust and NaOHAq (Hemilian, B. 19, 3068). Needles (from dilute alcohol). May be sublimed. Yields CHPh, when distilled with Ba(OH), Re-exidised by alkaline KMnO, to diphenyl-phthalide dicarboxylic acid.—CaA" 2aq: needles.—Ag.A": curdy pp.

Reference .- OXY - DI - PHONYL - METHANE CARB-OXYLIC ACID.

DIPHENYL . METHANE DISULPHONIC ACID $C_{13}H_{10}(SO_3H)_2$. [59°]. Got by sulphonation (Doer, B. 5, 796). Deliquescent plates. -K.A" aq: prisms (from dilute alcohol).—BaA".
-CuA" . green plates.

Tri-phenyl-methane trisulphonic acid $C_{19}H_{11}(SO_1H)$. Formed by warming CHPh, with fuming H_2SO_4 (Kckulė a. Franchimont, B_2 , B_3 , B_4 , B_4 , B_5 , B_4 , B_5 , B_5 , B_5 , B_5 , B_6 , B_6 , B_7 , B_7 , B_8 , needles, ppd. by adding alcohol to its aqueous solution.

DI PHENYL METHAZINE C, H12O, i.e. CHPh<\(\frac{N}{N}\) CHPh. [93°]. Formed by shaking a dilute solution of hydrazine with benzoic aldehyde (Curtius, J. pr. [2] 39, 44). Light-yellow prisms, v. sl. sol. hot water, v. sol. hot alcohol. Decomposed by boiling into CHPleCHPh and nitrogen, and by boiling dilute acids into benzoic aldehyde and hydrazine. Reduced in alcoholic solution by sodium-amalgam to di-benzyl-hydrazine, and by excess of Na to benzylamine.

PHENYL-METHENYL-AMIDINE v. BENZ-

· Diphenyl-methenyl-diamine is described as DI-PHENYL-FORMANIDINE.

PHENYL-METHENYL-AZIDINE C.H., N. i.e. NH, CH:N.HPh. [225°]. Formed from phenyl-hydrazine and HCy (Fischer, B. 22, 1934). Insol. water, v. sol. hot alcohol. The nitrate and hydrochloride are crystalline.

PHENYL METHENYL DI-ETHYL TRISUL-PHONE C.H., SO., CH(SO., C.H.). [166°]. S. 2 at 15°. Formed by oxidising PhS.CH(SO.Et). with alkaline KMnO, (Fromm, A. 253, 167; Laves, B. 25, 362). Snow-white needles, v. sol. alkalis.—KA': prisms.—BaA'₂: tables.

TRI PHENYL METHENYL TRIKETONE v. Tri-benzoyl-methane.

TRI.PHENYL METHENYL TRISULPHONE CH(SO,Ph). \$\, 215\circ\$. Formed by oxidising PhS.CH(SO,Ph), with alkaline KMnO, (Laves, B. 25, 348). Tables, v. sol. alcohol, insol. ether, m. sol. water.—KA': tablets.—BaA';—AgA'.

DI - PHENYL - DI - METHYL - ACETYLENE TETRAKETORE . DI-BENZOYL-DI-ACETYL-SHAHE

PHENYL-METHYL-ACRIDINE C.H., N i.e. C.H. C.CH:CMe. [136°]. Formed heating phenyl-p-toluidine with benzoic acid and ZnCl, at 260° (Bonna, A. 289, 62). Needles, sl. sol. water. Its alcoholic solution shows greenish-blue fluorescence. Yields phenylacridine carboxylic acid [253°] on oxidation .-B'HCl: yellow needles. B'HI. B', H. SQ, .-

B'C₆H₁N₃O₇. Red needles.—B'HI.—B'₂H₂SQ₅.—
B'C₆H₁N₃O₇. Red needles.
Phenyl-methyl-acridine dihydride
C₅H₄.—C₅H₄. [104°]. Formed by the action of MeI on phenyl-acridine dihydride; or by reduction of the methylo-chloride of phenyl-acridine with zinc-dust (Bernthsen a. Bender. B. 16, 1816). White needles or prisms. exidation with nitrous soid it gives the methylo-

hydroxide of phenyl-acridine.

PHENYL-METHYL-ALLYL-PYRROLE

CH:CMe
CH:CMe
NC,H, [52°]. (278°). Formed by

Paal, B. 18, 2595). Large colourless plates, Blue fluorescence. Extremely sol. all ordinary solvents.

PHENYL - METHYL - ALLYL - PYRROLE CARBOXYLIC ACID CO.H.C.=CMe>NC.H. [158°]. Obtained by saponification of its ether, which is formed by the action of allylamine upon acetophenone-acetoacetic ether (Lederer a. Paal, B. 18, 2594). Short glistening prisms.

alcohol, ether, benzene, and acetic acid. PHENYL-METHYL-AMIDO-ACETIC C.H., NO. i.e. CH. (NPhMe). CO.H. Phenylmethyl-glycocoll. Formed by heating chloroacetic ether with dimethylaniline and saponifying the product by boiling HClAq (Silberstein, B. 17, 2661). Liquid.—HA'HCl; prisms.

A mids. CH (NPhMe). CO.NH. [168°].

Formed by heating CH_CI.CONH, with NPhMe, or NPhMeH. Crystals, sol. hot water. Its hydrochloride forms easily soluble prisms.

Methylo-chloride CH2(NPhMe2Cl).CO2H. Formed by warming chloro-acetic acid with NPhMe, in ether (Zimmermann, B. 12, 2206). Needles. Moist Ag₂O forms an hydroxide.

Amide of the methylo-chloride CH₂(NPhMe,Cl).CO.NH, Formed by heating chloro-acetamide with dimethylaniline in alco-

PHENONE C.H., CO.CH., NPhMe. Phenacyl-methyl-aniline. [120°]. Formed by the action of NPhMeH or NPhMe, on \(\varphi\)-bromo-acetophenone (Staedel a. Siepermann, B. 18, 842; 14, 983; 21, 2196). Prisms (from alcohol). A solution of its hydrochloride gives a red pp. with dilute HNO, (Weller, B. 16, 27). ZnCl_forms Cl_Hu_N [102°].—B'_H_PtCl_s: tablos.—B'MeI. Crystals.—B'MeOH. Strongly alkaline.

PHENYL - METHYL - AMIDO - BENZENE

ACID NPhMe.C.H.,P(OH), PHOSPHINIC [150.5°]. Formed by the action of NaOHAq on the oily chloride NPhMe.C.H., PCl., which is formed by the action of AlCl, on a mixture of NPh_Me and PCl, (Michaelis, A. 260, 37). Small needles (from water) or plates (from alcohol),—NaHA" 2aq. [265°]. Plates, v. e. sol. water.

PHENYL-METHYL-AMIDO-BENZOIC ACID C₁₄H₁₈NO₂ i.e. C₄H₄(NPhMe).CO₂H. [184°]. Formed from NPh₂Me and COCl₂ (Michler a. Sarauw, B: 14, 2180). Plates.—BaA'₂: pearly plates.—AgA': white pp.

PHENYL-METHYL-AMIDO-ETHANE SUL-PHONIC ACID NPhMe.C.H., SO.H. Formed from CH_Cl.CH_, SO.H and methylaniline at 160° (James, J. pr. [2] 31, 417). Silky crystals (from

PHENYL - METHYL - AMIDO - ETHYL - PHTHALIMIDE C.H.O.N.C.H.NPhMe. [105°]. Formed from brono-ethyl-phthalimide and methyl-aniline at 165° (Newman, B. 24, 2199). Greenish-yellow four-sided tables, a c. sob CaHa.

PHENYL - METHYL AMIDO-METHENYL-AMIDO-PHENOL C, Ho, N,O i.e.

C.H. C.NPhMe. (above 360°). Formed

from C.H. C.SH and methyl-aniline (Kalckhoff, B. 16, 1825). Syrup, with blue fluorescence.—B'2H2PtCle: prisms.

PHENYL - METHYL - AMIDO-DI-METHYL-PYRROLE C₁₈H₁₆N₂ i.e. NPhMe.N CMe:CH [41°]. (310°). Formed by heating its dicarboxylioacid at 231° (Knorr, A. 236, 310). Crystalline mass, v. sol. alcohol. Volatile with steam.

Phenyl-methyl-amido-di-methyl-pyrrole dicarboxylic acid C₁₈H₁₆N₂O₂. Formed by saponification of its oily ether, which is formed from diacetyl-succinic ether and phenyl-methyl-hydrazine (K.). Prisms, decomposing at 231°. -AgA': flocculent pp.

PHENYL - METHYL - p - AMIDO - PHENOL. Methylderivative NPhMe.C.H.OMe. (813°). Formed from phenyl-p-amido-phenol, KOH, and MeI (Philip a Calm, B. 17, 2433), Oil, insol. NaOHAq. PHENYL - TETRA - METHYL - TRI-AMIDO-

DI-PHENYL-NAPHTHYL-CARBINOL

C.H.s.N.O. i.e. NPhH.C., H. C(OH)(C.H., NMc.)... [95°]. Base of Victoria Blue B. Formed by heating tetra-methyl-di-amido-benzophenone (10 pts.) with phenyl-(a)-naphthylamine (9 pts.), and POCIs (7 pts.) at 110° (Nathansohn a. Müller, B. 22, 1890). The base is set free by NaOHAq. Brick-red powder, v. sol. alcohol and benzene. — (C₃₃H₃₂N₃Cl)₂PtCl₄: violet needles. —C₃₃H₃₁N₃C₆H₂(NO₂)₃OH: dark-blue pp.

Phenyl - penta - methyl-tri-amido-di-phenyl-

naphthyl carbinol C₁,H₁,N₃O i.e. NPhMe.C₁₀H₂,C(OH)(C₂H₁,NMe₂)₂. [77°]. The chloride C₃,H₃₄N₁Cl, Victoria Blue 4 R, formed by the action of methyl-phenyl-(a)-naphthyl-amine on CO(C_eH₁NMe_e), in presence of POCl, is v. sol. hot water (Nathansohn a. Müller, B. 22, 1892). The carbinol is a brick red pp., v. sol. alcohol. It forms $(C_{24}H_{24}N_{2}Cl)_{2}PtCl_{4}$ and v. 801. accords. It forms (***14.35.7)2.
C1,1H_g/N,1C,H_g/NO_3,OH crystallising in very small dark-blue needles.
PHENGL - TETRA - METHYL - TRI AMIDO.

DI-PHENYL-NAPHTHYL-METHANE C,1H,1,N, i.e. NHPh.O.,H.,OH(O.H.,NMe.). [125°]. Formed by reducing the carbinol (v. supra) (Nathansohn a. Müller, B. 22, 1891). Flocculent pp., v. sol. hot alcohol. Yields B".H.,PtCl. and B"C.,H.,N.O., both being crystalline.

Phenyl-penta-methyl-tri-amide-di-phenylnaphthyl-methane ("H., N. i.e.

NPhMe.C., H., CH(C.H., NMe.)... [87°]. Formed
by reducing the carbinol (N. a. M.). Amorphous.

Yields crystalline B" H. PtCl, and B"C. H., N.O.,
PHENYL DI METHYL AMIDO TOLYL

KETONE C₆H₃.CO.C₆H₃Me.NMe₂. [67°]. (850°-360°). Formed from benzoic acid, di-methyl-otoluidine, and P.O. (O. Fischer, A. 206, 91).

PHENYL-TETRA - METHYL-DI-AMIDO-DI-

TOLYI. METHANE C₂₁H₃₀N, i.e. CHPh(C₆H₃Me.NMe₂)₂ [109°]. Formed by heating di-meth**9**1-m-toluidine with benzoic aldehyde and ZnCl₂ (Fischer, B. 13, 807). Prisms.

-B"H_PtCl_ 2aq: small yellow crystals.
PHENYL-METHYL-AMINE v. METHYL-ANIL-INE.

Phenyl-di-methyl-amine v. DI-METHYL-ANIL-

Di-phenyl-methyl-amine v. METHYL-DI-PHENYL-AMINE.

Tri-phenyl-methyl-amine TRI-PHENYL CARBINYLAMINE.

PHENYL-METHYL-ANTHRACENE i.e. CoH, Me CH CH [119°]. by distilling phenyl-methyl-anthranol with zince dust (Hemilian, B. 16, 2367). Yellow pointed crystals. Dissolves in alcohol and ether, with a strong greenish-blue fluorescence. By CrO, in acetic acid it is oxidised to phenyl-methyloxanthranol.

PHENYL-METHYL-ANTHRANOL C21H18O i.e. C_eH₃Me<CPh<C(OH)>C_eH₄. [157°]. Obtained by heating di-phenyl-tolyl-methane carboxylic acid with H₂SO₄ (Hemilian, B. 16, 2365). Yellow glistening tables. Sol. ether, boiling alcohol and acetic acid, insol. cold alkalis, but dissolves on boiling to a yellow solution. On oxidation is gives phonyl methyl-oxanthranol. PHENYL-DI-METHYL-ARSINE v. vol. i. p.

DI -PHENYL - DI - METHYL - AZIMETHYL. ENE N₂(CMePh)₂. [1213]. Found by the action of acetophenone on hydrazine hydrate or on CPhMe:N.NH., (Curtius, J. pr. [2] 44, 542). PHENYL-METHYL-BIAZOLE DIHYDRIDE

CH₂. NPh [140°]. Formed by the action OCCMe:N

of tin and HCl on O CCl. NPh [122°], which is made by the action of COCl, on acetyl-phenyl-hydrazine (Freund a. Kuh, B. 23, 2838). Yel-

lowish plates.
PHENYL-METHYL-TRIAZOLE C.H., N. i.e. N.NPh CH. Formed by heating its carboxylic acid to 180° (Bladin, B. 19, 2602). Oil. B'₂H₂PtCl₆ aq. [124°]. Lemon-yellow tables. PHENYL-METHYL-TRIAZOLE CARBOXY-

LIC ACID N.NPh C.CO.H. [177°]. Formed by saponifying its nitrile, which is got by the action of Ac.O on phenyl-hydrazine dicyanide and also by gently warming phenyl-hydrazine dicyanide with an alcoholic solution of pyruvic acid (Bladin, B. 18, 1544; 19, 2598; 22, 1749; 25, 185).

Salts. — CuA', 1 aq. — PbA', 2 aq. — AgA' 1 aq. — HA'HCl; tables (from HCMq).

Ethyl ether Eth'. Oil. Nitrile. [109°]. Prisms. Amêde C₂N,PhMe.CO.NH₂. [170°]. Prisms,

m. sol. water and alcohol.

Amidoxim C2N3PhMe.C(NH2):NOH. [210°]. Formed from the nitrile and hydroxylamine in alcohol. Plates (from alcohol), v. sl. sol. water. FeCl, colours its alcoholic solution deep red. Yields B'HCl and B',H,PtCl, [201°]. Ac,O forms C,N,PhMe.C(NH,):NOAc [148°] and $C_{2}N_{3}PhMe.C < N > CMe [105.5°]$. BzCl forms C₂N₃PhMe.C(NH₂):NOBz [1825°] converted by heat into C,N,PhMe.C N.O CPh [167°].

DI-PHENYL-DI-METHYL-TETRAZONE NPhMe. N.N.NPhMe. [137]. Formed by oxidising phenyl-methyl-hydrazine (Fischer, A. 190, 162; Tafel, B. 18, 1744). Monoclinic plates. With I in CHCl, it forms C, H, N, I, a black crystaltine pp. DI. PHENYL-DI-METHYL-DI-TRIAZYL

N.NPh>C.C≪NPh.N CMe.N>C.C≪N - CMe [223°]. Formed by CMe.N° N — Une heating the cyanide of phenyl-hydrazine with Ac.O (Bladin, B. 21, 3063). Prisms (from alcohol).—B"H₂Cl₂.—B"H₂PlCl₃ laq. Plates.

DIBHENYL METHYL-BENZAMIDINE

C_oH_o.C(NMe).NPh_o. Formed by heating di-phenyl-benzamidine with MeI at 130° (Bernth-

sen, A. 192, 17). Syrup. -B',H,PtCl_a: yellow pp.
PHENYL p.METHYL-BENZYL KETONE
C.H.,CO.CH.,CaH,Me. [94°]. Formed from ptolyl-acetic chloride, benzene, and AlCl. (Strassmann, B. 22, 1231). Yields an oxim [109°].
PHENYL-METHYL-BENZYL-UREA

NHPh.CO.NH.CH.,C,H,Me. [131°]. from m-methyl-benzylamine and phenyl cyanate (Brömme, B. 21, 2700).

TRI-PHENYL-METHYL-BROMIDE

BROMOSTRI-PHENEL-METHANE

PHENYL-METHYL-CARBAMIC ACID.

Ethyl ether NPhMe.CO.OEt. (241°). Formed from methylandine and Cl.CO.Et (Geb-

Formed from methylamine and Ch. O₂Et (Geshardt, B. 17, 3042). Yellow off.

Chloride, NihMe.COCl. [88°]. (280°).

Got by passing COCl₂ into a solution of methylamiline in benzene (Michler a. Zimmermann, B. 12, 1165). Tables (from alcohol), insol. water Reacts with toluene and aluminium chloride, forming NPhMe.CO.C.,H.Me [70°] while AlCl. and o. m., and p. xylene give rise to the compounds NPhMe.CO.C. H.Me. melting at 78°, 54°, and 74° respectively (Lellmann, B. 24, 2114).

Phenyl ether NPhMe.CO.OC, H., [58°]. Formed from the chloride and KOPh in alcohol (Lellmann a. Benz, A. 24, 2108). Large orystals.

Nitro-phenyl ethers C,H,(NO2)A'. The o., m., and p. nitro-phenyl ethers melt at 110°, 105°, and 70° respectively. They yield on reduction the corresponding amido-phenyl ethers melting at 103°, 94°, and 104° respectively.

p-Tolyl ether C.H.MeA'. [62°].

PHENYL-MEETHYL-SEMI-CARBAZIDE

NPhMe.NH.CO.NH. [138°]. Formed from phenyl-methyl-hydrazine hydrochloride and potassium cyanate (Fischer, A. 190, 164). Orystalline mass m. sol. hot water. Yields a nitrosamine NPhMe.N(NO).CO.NH, [77°].

Phenyl-di-methyl-semi-carbazide NMe., NH. CO.NHPh. [108°]. Formed from trimethylene bromide (Hanssen, B. 20, 781). phenyl-cyanate and di-methyl-hydrazine (Renout, Thick brown liquid.—B"H, SO,. [156°]. Needles.

B. 13, 2172). Pyramids. Decomposed by HCl into the parent substances.

Di-phenyl-di-methyl-carbaside CS(NH.NPhMe)2. [c. 168°]. Got by heating

phenyl-methyl-hydrazine with CS, (Stahel, A. 258, 250).

PHENYL-METHYL-CYANIDE v. Nitrile of PHENYL-ACETIC ACID.

Di-phenyl-methyl-cyanide v. Nitrile of Di-PHENYL-ACETIC ACID.

Di-phenyl-methyl dicyanide C. H. N. i.c. N CMe.N CPh. [110°]. (227° at 15 mm.). Formed from benzonitrile, AcCl, and AlCl, (Krafft a. Hansen, B. 22, 803; 23, 2382). Needles, sol. alcohol and hyroin. Decomposed by diluted H.SQ, into benzoic acid, acetic acid, and NH. Oxidised by alkaline KMnO, to C₃N_xPh_xCO₂H [c. 192°] which on hesting yields C₄N_xPh_xH [75°] (205° at 9 mm.).

Salts.—B'HCl: needles.—B'₂H_xPtCl_s.
DI - PHENYL - METHYLENE - p - AMIDOBENZOIC ACID *CPh_x:N.C₂H_x:CO₂H. [240°]. Formed from Ph_xCCl_x and p-amido-benzoic acid

Formed from Ph₂CCl₂ and p-amido benzoic acid (Hantzsch a. Krafft, B. 24, 3522). Short prisms. PHENYL-METHYLENE-AMINE CH,;NPh

or CH2 NPh CH2? [140°]. Formed by adding aniline to a solution of formic aldehyde (Wellington a. Tollens, B. 18, 3809). Formed also from trioxymethylene and aniline (Kolotoff, J. 1885, 777). Long slender needles. Decomposed by water at 100° into trioxymethylene and aniline.

Phenyl-trimethylene-diamine NIIPh.C₂H_e.NH₂ (282° cor.). S.G. 2 1.0356. A product of the action of Na on an alcoholic solution of phenyl-pyrazole (Balbiano, G. 18, 354; 19, 688; Rend. Accad. Linc. [4] 4, ii. 44). Formed also by boiling phenyl-y-amido-propyl-phthalimide with HClAq (Goddenring, B. 23, 1169). Oil. Sulphide of carbon forms NHHA.C.,H.,NH.CS,SNH.Ph.C.,H.NH., crystallising from alcohol in white plates.—B"2HCl: tufts of needles, v. e. sol. water. When heated it gives off NH₃ and NPh:C₄H₄, which forms (C₄H₁₁,N)₂H₂PtCl₄·-C₄H₁₁N₂Q₄H₂N₂O₅. Greenish crystals, decomposing at 195°.—Succinate

[100°]. Phonyl-di-trimethylene-triamine NPh(CH_CH_CH_NH_)r Formed by heating its phthalyl derivative with HClAq at 240° (Goldenring, B. 23, 1170). — B'''8HCl. —

B,""3H2PtCl. Di-phthalyl derivative NPh(CH₂CH₂CH₂N:C₄H₄O₂)₂ [145°]. Formed from y-bromo-propyl-phthalimide and aniline.

Di-phenyl-methylene-amine CPh₂:NH.

Formed by heating CPh₂Cl₂ with carbamic ether at 130° (Hantzsch a. Krafft, B. 24, 3517). Colourless liquid.-B'HCl: snow-white powder.

Di-phenyl-methylene-diamine CH_(NHPh)2. [49°]. Formed hy mixing a large excess of an aqueous solution of aniline with formic aldehyde solution (Pratesi, G. 14, 351; cf. Lermontoff, B. 7, 1255). Four-sided tables, sol. alcohol. Its hydrochloride is unstable.—B"H₂PtCl₈.

Di-phenyl-trimethylene-diamine CH₂(CH₂NHPh)₂. Formed from aniline and trimethylene bromide (Hanssen, B. 20, 781). Nitrosamine CH2(CH2, NPh.NO)... | DI-PHENYL-METHYLENE-ANILINE

NPh:OPh. [109°]. (above 360°). Formed from CPh.Cl. and aniline (Pauly, A. 187, 199). Yellow tables (from ether). Split up by HClAq into aniline and benzophenone.

TETRA - PHENYL - DI - METHYLENE . TETRAZONE N₂(N:CPh₂)₂. Formed by shaking a bonzene solution of NH₂,N:CPh₂ with HgO (Curtius a. Rauterberg, J. pr. [2] 44, 200). Red needles. Decomposes readily into nitrogen and CPh.:N.N.CPh. Gaseous HBr ferms OPh.HBr

DI-PHENYL-TRIMETHYLENE DI-CARB. AMIC ACID.

Ethyl other OH (CH2. NPh. CO2Et), [560]. Formed from the chloride and NaOEt (Hanssen, B. 20, 783). Crystallines

Ohlowide CH,(CH,NPh.COCI)2. [102°]. Formed from CH2(CH2NPhH), and COCl2 in benzene. Needles.

PHENYL-TRIMETHYLENE DICARBOXYLIC ACID CHPh CH.CO.H. [175°]. Got by saponisying its ether. Prisms, m. sol. water, v. sol. alcohol and ether (Buchner a. Dessauer, B. 21, atonoi and etner (Duchner a. Debauci, S. Z., 2646; 25, 1152). When heated in vacco it yields an anhydride C, IH, O, [184°]. —NaHA": needles. Di-methyl ether Mc, A". [68°]. Ethyl ether Et, A" (257° at 120 mm.). NCHD,

Formed by distilling CO₂Et.CH N.CHPh N.CH.CO₂Et

in vacuo. Thick oil.

Phenyl-trimethylene-tri-carboxylic acid C3H2Ph(CO2H)3. [188°]. Got by saponifying its

whethy lether Me,A" [47°]. (210° at 20 mm.). Formed from NaOMe, methyl malonate, and methyl di-bromo-phenyl-propionate.

PHENYL METHYLENE ETHYL DIKETONE C.H.,CO.CH.,CO.C.H., Propionyl-acetophenone. (277°). S.G. 12 1-081. Formed from acetophenone, propionic ether, and NaOEt (Stylos, B. 20, 2181). Liquid.

DI-PHENYL-METHYLENE-HYDRAZINE CPh.;NNH. [98°]. (c. 227° at 55 mm.). Hydraside of benzophenone. Formed by heating benzophenone (5 g.) with hydrazine hydrate (18 g.) and Mcchol (1 g.) at 150° (Curtius a. Lauterberg, J. pr. [2] 44, 192). Prisms (from alcohol). Reduces alcoholic AgNO, forming a mirror. Reduces Fehling's solution on warming. Boiling dilute H₂SO, splits off hydrazine. Reacts readily with ketones. —B'HCl. [183°].

Acetyl derivative. [107°]. Prisms.
Bensoyl derivative. [116.6°]. Prisms.
Tetra-phenyl-di-methylene-hydrasine

Tetra-paenyl-at-metalytene-nyarasane CPh₂:N.N:CPh₂. Di-phenyl-ketazine. [162°]. Formed by boiling CPh₂:N.N:H₂ with iodine in alcohol. Yellow prisms, v. sl. sol. hot water, sol. alkalis. Decomposed by boiling dilute H₂SO, into benzoplenone and N₂H₄SO.

Phenyl - trimethylene - hydrasine C,H12N, [58°]. Got from phenyl-hydrazine and tri-methylene bromide (Marckwald, C. C. 1888, 1410). Converted by trimethylene bromide on further heating into (PhN_s),(C,H_s), [226°].

DI-PHENYL METHYLENE DIKETONE CH2(CO.C8H3)2. Benzoyl-acetophenone. benzoyl methane. [81°]. (over 200°).

Formation.—1. By boiling di-bensoyl-acetie acid with water (Baeyer a. Perkin, jun.; B. 16, 2134; C. J. 47, 240).—2. By the action of malonyl chloride and AlCl, upon benzene (Auger, A. Ch. [6] 22, 348).

Preparation.—By adding dry sodium ethylate to a mixture of acetophenone and benzoic ether, the reaction taking place with spontaneous heating. The crystalline mass is extracted with cold water, finally with dilute NaOH, and from the solution of the sodium salt the ketone is precipitated by means of CO₂; the yield is 0.50 p.c. of the acetophenone used (Claisen, B. 20, 655).

Properties.—Trimetric plates, v. sol. alkalis. C. Yields products of substitution by treatment with NaOEt and alkyl iodides.

Reactions .- 1. Bromine (1 mol.) in CHCl. forms Bz,CHBr [93°], which on heating with HOAc and KOAc yields Bz,CHOAc [94°], which on further bromination gives Bz, CIPr.OAc [102°] which is split up by heat into Ph.CO.CO.CO.Ph and AcBr.—2. Excess of bromine (2 mols.) in CHCl, forms Bz,CBr, [95°] whence HOAc and KOAc form di-phenyl triketone. - 3. Amyl nitrite and alcoholic HCl give Bz,C:NOH [146°], converted by nitrous acid into the triketone (Keufville a. Pechmann, B. 22, 852; 23, 3376).—4.
Phenyl-hydrazine forms tri-phenyl-pyrazole (Japp a. Klingemann, B. 22, 2886)

PHENYL METHYLENE METHYL DI-KETONE v. BENZOYL-ACETONE.

PHENYL METHYLENE METHYL SUL-PHONE-KETONE C.H., SO., CH., CO.CH., Acetonyl phenyl sulphone. [57]. Formed by oxidising PhS.CH Ac with KMnO, (Delisle, A. 260, Formed also from chloro-acetone and 262). Formed also from chloro-acetone and C₂H₂SO₂Na (Otto, B. 19, 1642; 21, 1871; 23, 756; J. pr. [2] 36, 402). Plates, sol. water and alcohol. Yields a phenyl-hydrazide [129°] and an oxim [148°]. Ammonia yields the compound NH:CMe.CH_SO_Ph [111°]. Phenyl mercaptan yields (PhS)₂CMe.CH₂SO₂Ph [104]. Potash yields (PhS)₂CMe.CH₂SO₂Ph [104]. Potash yields phenyl methyl sulphone. Br forms a hromo-derivative [96°] and a di-bromo-derivative bromo-derivative [96°] and a di-bromo-derivative

PHTHALIMIDINE C₁₃H₁₁NO s.e. O₄H₄CO NPh. [100°]. Formed by heating acetophenone o-carboxylic anilide at 230° (Mertens, B. 19, 2372). Prisms, v. sol. alcohol. An isomeride [265°], got by treating acctophenone o-carboxylic anilide with conc. H₂SO₂, is sl. sol. alcohol.

DI-PHENYL METHYLENE DISULPHONE CH_(SO,Ph). [119°]. Formed by oxidation of CH_(SPh), which is got by boiling CH,Cl, with NaSPh (Fromm, A. 253, 161). Needles, v. al. sol. boiling water.

DI. PHENYL. DI. METHYLENE DI. SUL. DI. PHENYI. DI. METHYLENE DI. 8UL. PHONE KETONE C., II, S.O., i.a. CO(CH.SO.Ph)., [150°]. Got from CHBr. CO.CH. SO.Ph and C.H., SO.Pha. Got also from CO(CHCl.), and O.H., SO.Pha (Otto, B. 19, 1542; 22, 1967). Small crystals (from HOAc). Yields an oxim [187°] and a phenyl-hydrazide [171°]. PhSH forms (PhS). C(CH. SO.Ph)., [191°].

DI. PHENYI. METHYLENE DI. THIO-GLY. COLLIC ACID CPP., (S.CH., CO.H)., [176°].

COLLIC ACID CPh.(S.CH.,CO.H). [176°]. Formed by heating benzophenone with thioglycollic acid and ZnCl. (Bongarts, S. 21, 488). Needles (from dilute HOAc), insol. hot water.

PHENYL-TRIMETHYLENE-THIO-UREA

OS NH .CH. CH. [215°]. Formed by boiling NHPh.C₂H_a.NH.CS.8NPhH_r-C₂H_a.NH_r with water (Goldenring, B. 23, 1172). White prisms. Di-phenyl-methylened-thio-urea C₁₁H₁₂N₂S

i.e. S

C(NPh)

NPh. [68°]. Formed from di-phenyl-thio-ures and CH,I. (Foerster, B. 21, 1872). Thin needles, v. c. sol. alcohol.— B',H,PtCl. Crystalline pp.
Di-phenyl-trimethylene-\psi-thio-urea

B<C(NPh)-NPh CH,CH,CH, . [123°]. Formed from diphenyl-thio-urea and trimethylene bromide (F.). Di-phenyl-trimethylene-di-thio-di-urea

CH,(CH,NH.CS.NPhH)2. Formed from phenylthiocarbimide. trimethylene-diamine, alcohol (Lellmann a. Würthner, A. 228, 236). Plates [115°] or nodules [60°], v. sol. alcohol.

Tri-phenyl-trimethylene-di-thio-di-urea NHPh.CS.NH.CH, CH, CH, NPh.CS.NHPh. [145°]. Formed by heating phenyl-trimethylene-diamine (1 g.7 with phenyl-thiocarbimide (2 g.) and alcohol (15 c.c.) (G.). Slender needles.

DPPHENYL-METHYLENE-p-TOLUIDINE C.H.MeN:CPh. (above 360°). Formed from Ph.CCl, and p-toluidine (Pauly, A. 187, 214). Oil, split up by acids into p-toluidine and benzophenone.

PHENYL-TRIMETHYLENE-UREA

 $CO < NPh.CH_2 > CH_2$. [215°]. Formed by heating phenyl-amido-propyl-urea at 240° (Goldenring. Yellowish plates, sl. sol. hot Aq. B. 23, 1173). Di-phenyl-trimethylene-urea

CO NPh.CH₂ CII₂. [156°]. Formed, together with CH₂(CH₂, NPh. COCl), [102°], from di-phenyl-trimethylene-diamine and COCl, in benzene (Hanssen, B. 20, 782). Plates.

Tetra-phenyl-trimethylene-di-urea
CH₂(CH₂,NPh.CO.NHPh). [153°]. Form
from CH₂(CH₂,NPh.COCI), and aniline (H.).
PHENYL TRIMETHYLENYL KETONE Formed

C.H., CO.CH C.H. or C.H.; CPh O. Benzoyl-trimethylene. Phenyl-furfurane dihydride (239°) at 720 mm. V.D. 5-27 (cafe. 5-04). Formed by heating its carboxylic acid at 200° (Porlkin, jun., B. 16, 2140; C. J. 47, 842). Oil with aromatic odour. Alcoholic hydroxylamine forms the oxim in the cold, but by heating the ketone with alcoholic hydroxylamine hydrochloride at 135' there are formed C₂₃H₁₇N₃O₃ (a red amorphous powder) and C₃₆H₂₈N₃O₂ (a black brittle mass which forms deep-blue B"H₂Cl₂ and B"H.PtCl.).

[87°]. Colourless plates.

TRIMETHYLENYL KETONE CARBOXYLIC ACID CH₂>CBz.CO₂H. [149°], Formed by saponification of the ether. Monoelinic prisms; a:b:c=2.380:1:2.132; $\beta=83^{\circ}4'$. M. sol. ether, \bullet sl. sol. water. Decomposed by water at 110° into phenyl oxypropyl ketone CH_OH_CH_CH_Bz which when extracted with ether and dried over K.CO, is found to have split off water, the resulting anhydride being possibly phesyl trimethylenyl ketone (Perkin, C. J. 31, 837). - AgA': flocculent pp.

Ethyl other Et.A". (282°) at 720 mm. Formed from benzoyl-acetic ether, ethylene bromide, and NaOEt (Perkin, B. 16, 2188; C. J. 47, 841). Oil.

Reference.-NITBO - PHENYL - TRIMETHYLENYL

METONE CARROXYLIC ACID.

PHENYL-METHYL-ETHYLENE-DIAMINE NH.CH.CH.NPhMe. (255°). Formed by the action of HCl on C.H.C.O...N.C.H.NPhMe (Newman, B. 24, 2200). Liquid, v. sol. water and alcohol.—B'C.H.(NO.),OH. [173°], Needles-

Di phonyl di-methyl-ethylene-diamine C,H,(NPhMe),. The methylo-bromide B"Me,Br, got by heating di-methyl-aniline with ethylene bromide (Hijbner, A. 224, 846), crystallies in deliquescent prisms and fields B"Me₁(OH), B"Me₂Cl₂, B"Me₂PtCl₄, B"Me₂Cl₃HgCl₃ [174°], B"Me₄L₅, B"Me₂Cr₂O₃, and B"Me₂(C₄L₃N₂O₃), [1240

PHENYL-METHYL-ETHYLENE Its carb-TONE v. Acerophenone-acerone. oxylic acid is described as ACETOPHENONZ-ACETO-

ACETIC ACID.

DI - PHENYL - DI - METHYL - v - ETHYLENE-DI-PYRROLE-DI-CARBOXYLIC ACID

CO, HC:CMe N.C, H, N CMe:C.CO, H HC:CPh N.C, H, N CPh:CH [1817]. Obtained by saponification of its ether, which is formed by mixing acetophenone-aceto-acetic cther with ethylene-diamine (Paal a. Schneider, B. 19, 3158). Crystalline solid. Sl. sol. alcohol, acetic acid, and conc. HCl, insol. other ordinary solvents. On heating above 180° it evolves CO, giving the free base.

Di-ethyl-ether Et,A": [1979]; plates; distillable under ordinary pressure; sol. alcohol, benzene, chloroform, and acetic acid, insol.

water and petroleum-spirit.

PHENYL-METHYL-ETHYL-080TRIAZOLE $NPh < N:CMe \atop N:CEt$. (270°). Formed by condensation of the oxim-phenyl-hydrazide of CH, CO.CO.C, H, (Pechmann, A. 262, 312). Needles. Yields a di-nitro-derivative [113°]. Oxidised by alkaline KMnO, to phenyl-methyltriazole carboxylic acid.

PHENYL - METHYL - ETHYL - PYRAZOLE $NPh < _{CEt;CMe}^{N=CH}$. (283°). S.G. 15 1.0476. Got by the action of phenyl-hydrazine C₂H₃.CO.CHMe.CHO (Claisen, B. 22, 3276).

Reference .- OXY - PHENYL - METHYL - ETHYL -

PYRAZOLE. TRI - PHENYL - METHYL - ETHYL - THIO-BIURET C.S., N., Ph., MeEt. [157°]. Formed from di-phenyl-ethyl-thio-urea and (Billeter a. Strohl, B. 21, 108). An isomeride [156°] is formed from di-phenyl-methyl-urea and NPhEt.CSCl. Both bodies crystallise in needles, sl. sol. alcohol.

PHENYL - METHYL - ETHYL - THIO - UREA CS(NHMe).NPhEt. Got from methyl thiocarbimide and ethvl-aniline (Gebhardt, B. 17, 8037). Crystalline solid.

Di-phenyl-methyl-ethyl-thio-urca CS(NPhMe).NPhEt. [49.50]. Formed from methyl-aniline and NPhEt.COCl (Billeter, B. 20, 2). Monoclinic crystals.
PHENYL-METHYL-FURFURANE C₁₁H₁₀O, 1632).

i.e. CH:CMe Or Oxyphenyl-pentamethenyl

hydride CH_aCH_aCO. [40°]. (c. 238°). Formed by heating phenythronic acid, and prepared by warming acetophenone-acetone with fuming HClAq, the yield being 65 p.c. (Paal, B. 17, 2769; Fittig, B. 21, 2134; A. 250, 222). Needles or prisms, insol. water and alkalis, volatile with steam. Br forms C₁₁H_aBr₃O [210°]. Phenylhydrazine forms a compound [165°-175°], crystallising from alcohol in golden panagles.

Tet†ahydride CHr. CHPh. O. (c. 230°).

Formed by reduction in alcoholic solution by
Na. Oil, miscible with alcohol and ether.

Na. Oil, miscible with account and central PHENYL METHYL-FURFURANE CARBOXYLIO ACID O. Ho. o. CO. H.C.CMe. HC.CPh. O. HC.C

Phenyl-methyl-furfurane carboxylic acid C₁₂H₁₀O₂ i.e. CO,H.C=CPh>O or

CO₂H.CH.CPh CH. Phenuvic acid. [145°].

Formed by heating phenythronic acid (Fittig, B. 21, 2134). Its ether is obtained from chloro-acetone and sodium benzoyl-acetic ether (Colefax, C. J. 59, 190). Long silky needles.—Cah', 2aq.—Bah', aq.—Agh': amorphous pp.

Phenyl-methyl-furfurane dicarboxylic acid

C₁₁H₁₀O₄ i.e. CO₂H.CH. CPh CC.CO₂H or

CO₂H.C:CMe O. Phenythronic acid [193°].

Formed by saponifying its ether with boiling baryta (Fittig, 4.250, 216). Silky needles, m. sol. hot water, v. sol. alcohol.—CaA" Saq. S. 5.—BaA" aq.—Ag₂A": crystalline pp.

Mono-ethyl ether EtHA". [112°].

Mono-ethyl ether EthA". [112].
Formed by the action of Ac₀O on a mixture of sodium succinate and benzoyl-acetic ether.—
Ca(EtA'); crystalline nodules (from alcohol).—
Ba(EtA''),—AgEtA''; white amorphous pp.
Diethyl ether EtA''. [44:52].

PHENYL-METHYL-GLYCOCOLL v. PHENYL-

PHENYL-METHYL-GLYOXALINE C₁₀H₁₀N₂
i.e. CMe≪N-C;H. [159°]. Formed by heating phenyl-methyl-oxazole with alcoholic NH, at 230° (Lewy, B. 22, 2195). Needles, v. sl. sol. alcohol. Salts.—B'HCl. [242°]. Needles.—B'₂H₂PtCl₂ 2aq. [212°]. Yellow prisms.
Phenyl-di-methyl-glyoxaline C₁₁H₁₂N₂ i.e.

Phenyl-di-methyl-glyoxaline $C_{11}H_{12}N_2$ i.e. $CPh \stackrel{N}{\sim} NHCMe$ [230°-234°]. Formed by heating diacetyl with benzoic aldehyde and alcoholic NH, (Wadsworth, C. J. 57, 8). Needles (from benzene).— $B'_2H_2PtCl_4$; needles. Di-phenyl-methyl-glyoxaline

OMe N—(Ph. [235°]. Formed by the action of aldehyde and NH, on benzil (Japp, C. J. 49, 466; 51, 557; C. J. Proc. 3, 34). Trimetric crystals; abic=1:207:1:1:920. Crystallises with diphenylglyoxaline (1 mol.), the compound melting at 218°.

PHENYL-METHYL-HYDANTOIC ACID C₄H,NH.CO.NH.CH(CH₃).CO₂H [170°]. Formed by the combination of phenyl cyanate with alanine and boiling the product with alcoholic KOH (Kühn, B. 17, 2884). Glistening scales.

PHENYL-METHYL-HYDANTOIN

CHPh CO. NMe [162°]. Formed from phenylhydantoin, KOMe, and MeI (Pinner, B. 21, 2325). Needles, sl. sol. cold alcohol.

*s-PHENYL-METHYL-HYDRAZINE

Och-NH.NHMe. Hydraso phenyl methyl.

Got by saponification of its dibenzoyl derivative, which is formed by heating NPhBz.NBzH with NaOMe and MeI (Intel, B. 18, 1740). Obtained also by the action of alkalis on nitroso-antipyrin (Knorr, A. 238, 137). Oil, oxidised by HgO to PhN:NMe. Reduces Fehling's solution and ammoniacal AgNO, in the cold.—B'₂H₂SO, [180°].—Oxalate: white needles.

Di-benzoyl derivative PhNBz.NMeBa. [145°]. Crystals, v. sol. alcohol and ether.

u-Phenyl-methyl-hydrazine NPhMe.NH₄. (227° i.V.) at 745 mm. Formed by converting methyl-aniline into phenyl-methyl-nitrosamine, and reducing this body (5 pts.) by zinc-dust. (20 pts.), HOAc (10 pts.), and water (35 pts.) at 0° (E. Fischer, A. 190, 152; 236, 199).

Properties.—Colourless oil, turning brown in air; m. sol. hot water, miscible with alcohol.

Reactions.—1. Nitrons acidyields NPIMe.NO, water, and N.O.—2. Diazobenzene nitrate solution forms PhN, and methyl-aniline nitrate.—3. HgO added to its solution in chloroform produces NPIMe.N.N.NPIMe [137°].—4. Reacts with aldehydes and ketones in the same way as phenyl-hydrazine, forming products of condensation; thus benzoic aldehyde forms NPIMe.N:CHIPh [104°] (Ebers, A. 227, 340), acctophenous forms NPIMe.N:CMePh [50°], acctone forms C₁H₁,N₂ (216°) (Degen, A. 236, 152), propionic aldehyde yields O₁,H₁,N₂ (198° at 170 mm), glucous yields C₂,H₁,O₂,N.NPIMe[171°], while benzil yields Ph.CO.CJPh.N.PIMe [56° and N.PhMe:CPh.CPh:N.PhMe[180°] (Kohlrausch, A. 253, 16; Fischer, B. 22, 87).—5. CS₂ at 100° forms CS(NH.NPIMO)₂ [c. 168°] (Stahel, A. 258, 250).—6. Nitroso-aniline forms C₁,H₁,N₂ O [151°], while nitroso-dimethylaniline gives C₁,H₁,N₂ O [141°] (O. Fischer, B. 22, 622).—7. With PhN:SO it forms PhNMe.N:SO [77°] crystallising from alcohol in yellow needles (Michaelis, A. 270, 120).

Salt.—B'.H.SO.: plates, v.e. sol. water. Actyl derivative NPhMe.NHAc. [93°]. Prisms, m. sol. hot water. Converted by Na and McI into NPhMe.NMcAc [68°], which is not decomposed by alkalis, but gives methylaniline when boiled with HOlAq.

Benzoyl derivative NPhMe.NHBz, [153°]. Formed by heating NPhH.NHBz with NaOMe and MeI. Needles (Tafel, B. 18, 1743).

NaoMe and Mel. Needles (Tafel, B. 18, 1743). Sulphonic acid SOJI C.H.NMe.NH.Formed by heating with fuming H.SO. (Pfülf, A. 239, 219). Plates.—NaA'aq: slender needles.

PHENYL-METHYL-IMESATIN v. Anilide of Methyl Isatin.

DI - PHENYL METHYLIMIDO - DI - ETHYL DISULPHONE NMe(C₂H, SO₂Ph)₂. Formed by heating NH(C₂H, SO₂Ph) with alcehol and MeI at 115° (Otto, J. pr. [2] 30, 335).—B'HCl²221°].

PHENYL-METHYL-INDOLE C,H,N ... C.H. CH CPh. [101°]. Formed by heating the phenyl-hydrazide of acetophenone with ZnCl, at 130° (Fischer, B. 19, 1565; Degen, A. 236, 155). Formed also by heating CH, Bz. NMePh with ZnCl, at 180° (Staedel, B. 21, 2196; Culmann, B. 21, 2596), and by heating the isomeric C.H. CPh OH with ZnCl₂ at 220° (Ince, A. 253, 40). Needles (from alcohol). Colours pinewood, moistened with HCl, dark-red.

C_•H_•<^{CAc}_{NMe}>CPh. Acetyl derivative [136°]. Formed by heating CH2Ac.CPh:N.NMcPh with ZnCl, at 150°. Needles (from dilute HOAc). C,H,<CPh NMeSCH. Phenyl-methyl-indole

[65°]. Formed from phenyl-acetic aldehyde and phenyl-methyl-hydrazine (Ince, A. 253, 38). Crystals, v. sol. benzene. Colours acidified pine-Crystals, v. soi. benzene.a. conours wood reddish-violet.—B'C₆H₄N₇O₇, [90].

Phenylemethyl-indole C₆H₄(CNH) CMe.

[60°]. Formed by heating the phenyl-hydrazide of benzyl methyl ketone with ZnCl₂ (Trenkler, A. 248, 110). Prisms (from ligroin).—Picrate: [142°]; v. sol. benzene.
PHENYL METHYL KETONE v. Aceto-

PHENONE.

Phenyl methyl diketone C₆H₃.CO.CO.CH₅. Acetyl-benzoyl. (217°). S.G. ¹⁴ 1·1041. S. ·26 at 20°. Formed by distilling its oxim Bz.C(NOH)Mo with dilute H₂SO₄ (Von Pechmann, B. 21, 2119; 22, 2129) or with isoamyl nitrite (Manasse, B. 21, 2177). Heavy oil, volatile with steam.

Oxim C.H. CO.C(NOH).CH. Nitroso-pro-piophenone. [114°]. Formed by the action of isoamyl nitrite and HCl or NaOEt on the ketone (Claimon a. Manasse, B. 22, 529). Prepared by the action of nitrous acid on hearzyl-propionic ether (1 mol.) and KOHAq (3 mols.) (P.; Gude-man, B. 22, 562). Needles (from hot water), forming a deep-yellow solution in albalis. SnCl. and HCl yield hydroxylamine and phenyl methyl diketone. Reduced by sedium-amalgam to a base which crystallises from alcohol in needles [108°].

Di-oxim Ph.C(NOH).C(NOH).Me. [236°]. Formed from the mono-oxim and hydroxylamine hydrochloride. Needles (from dilute alcohol).

Phenyl hydrazide C15H14N2O. [145°] Di-phenyl-di-hydrazide CMe(N₂HPh).CPh(N₂HPh). [1 [105°]. Yellow crystals, v. sol. ether.

Oxim-phenyl-hydrazide

CPh(N2HPĥ).CMe:NOH. [202°]. White needles. Phenyl methyl triketone. Mono-oxim C.H.,CO.C(NOH),CO.CH. [124°]. Formed by the action of nitrous acid on phenyl methylene methyl diketone (Ceresole, B. 17, 814). Needles,

v. sol. benzene, sol. alkalis.

Di-oxim C.H., C(NOH). C(NOH). CO.CH. [178°]. Formed by neating the mono- oxim with hydroxylamine hydrochloride. Needles, insol. cold water, sol. alkalis.

PHENYL METHYL-KETONE CARBOXYLIC ACID v. BENZOYL-ACETIC ACID and ACETOPHENONE CARBOXYLIC ACID.

PHENTL-METHYL-MALONIC ACID v. Ben-EXE-MALONIC ACID.

Tri-phenyl-methyl-malonic ether Formed CPh.CH(CO,Et)2 [133·5°]. CPh,Br and sodium malonic ether (Henderson, B. 20, 1014; C. J. Proc. 2, 251). Needles (from alcohol). Yields tri-phenyl-propionic acid when heated with alcoholic potash.-NaA'aq: needles. -BaA', aq. -AgA': minute white crystals.

PHENYL - DI - METHYL - NAPHTHALENE TETRAHYDRIDE v. METHBONOL.

BHENYL - METHYL - (β) -NAPHTHOTRIAZ-INE DIHYPRIDE C18H13N3 i.e. C18H4 N.NPh

Formed by adding aldehyde to a mixture of benzene-azo-(β)-naphthylamine and alcohol (Goldschmidt a. Poltzer, B. 24, 1004). Plates, v. sol. hot alcohol. Ph. 16. [252°].—B'_H_PtCl. Yellow needles.-B'MeI. [244°].-B'2Me2PtCl. [260°]. Yellow needles.

PHENYL - METHYL-(6)-NAPHTHYL-THIO-URDA C, H, N.Si.e. NPhMe.CS.NHC, H, [127°]. Formed from (3)-naphthyl thiocarbimide and methyl-aniline (Gebhardt, B. 17, 2091). Yellow needles.

PHENYL - METHYL - NITROSAMINE Nixosamine of Methyl-aniline, vol. iii. p. 285. PHENYL-METHYL-OSOTRIAZOLE

 $NPh <_{N:CM_0}^{N:CH}$ $(242^{\circ}).$ S.G. ¥. 1·1071. Formed by oxidising the diphenyl-hydrazide of pyruvic aldehyde and warming the resulting NPh.N:CMe. Formed also by the action of NaOH on CH, C(N, HPh). CH: NOAc (Pechmann, B. 21, 2751; A. 262, 279). Oil. Yields a trinitro-derivative [138°], and a sulphonic acid, of which the Na salt crystallises in hexagonal plates.

Phenyl-di-methyl-osotriazole

NPh N:CMe [35°]. (354°). Formed by heating the phenyl-hydrazide-oxim of diacetyl with Ac.O (P.). Crystalline, insol. water, sol. conc. HClAq, but reppd. by water. Yields a dinitro- derivative [1390] and a tri-nitro- derivative

PHENYL-METHYL-080TRIAZOLE CARB-NPh<N:C.CO.H. ACID Formed by oxidising phenyl-di-methyl-oso-

Needles, v. sl. sol. water. AgA': white pp.
PHENYL-METHYL-OXAMIDE C,H,s,N,2O,2 i.c. NHPh.C.O., NHMe. [180°]. Formed from NHMe.C.O., OEt and aniline (Wallach, A. 184, Needles.

PHENYL-METHYL-OXANTHRANOL

C21H18O2 i.e. C6H2Me CO CPh(OH) C6H4. [195]. Formed by oxidation of phenyl-methyl-anthranol with K₂Cr₂O₇ and HOAc (Hemilian, B. 16, 2366). Trimetric tables, v. sol. hot alcohol, insol. alkalis. Conc. H.SO, forms a purple solution.

Isomeride $\left[1:\frac{4}{5}\right]C_{\bullet}H_{\bullet}Me < \frac{CPh(OH)}{CO} > C_{\bullet}H_{\bullet}$ [213°]. Formed by oxidising di-phenyl-tolyl-methane o-carboxylic acid with K₂CrO₄ and conc. H.SO. (Hemilian, B. 19, 3064). Prisms, insol. alkalis. Reduced by zinc-dust to a phonyi-methyl-anthranol.

PHENTL-METHYL-OXAZOLE C., H, NO i.e. OCPh:CH [45°]. (242°). Formed by heating acetamide with bromo-acetophenone at 125° (Blümlein, B. 17, 2579; Lewy, B. 20, 2576; 21, 924). Needles (from sloohol). Yields benzoie acid on oxidation. Na and alcohol form an oily tetrahydride $C_{10}H_{13}NO$ (251°), which yields crystalline $C_{10}H_{13}NO$ (140°). HI and P give oily $C_{10}H_{18}$ (c. 275°). Conc. nitric acid forms $C_{10}H_{4}(NO_{2})NO$ (157°), which may be reduced to $C_{10}H_{4}(NH_{2})NO$ (115°). Hydroxylamine, phenylatic states of the state of the states hydrazine, and hot zinc-dust have no action. B'HCl.—B',H,PtCl, 2aq.—B'C,H,N,O, [134°].

Phenyl-methyl-omzole O CPh: CM: (240°).

Formed by boiling benzamids with chloro-acetone (Lewy, B. 21, 2193). Oil with fruity odour.—B₂H₂PtCl₂ 2aq. [170]. Yellow needles. Dihydride O<CPh=N₂ (244°). F6-med

by the action of KOH on bromo-propyl-benzamide in hot aqueous or alcoholic solution, the product being distilled with steam (Gabriel a. Heymann, B. 23, 2499). Liquid. Part'y converted, by evaporation with excess of HClAq (or HBrAq), into \$-chloro- (or bromo-) propyl-benz-amide [78°] (or [73°]). Boiling with an equiva-lent of HClAq yields \$-amido-propyl benzoate. B',H,PtCl,—B',H,Cr,O,—B'C,H,N,O,(167°). PHENYL-TRI-METHYL-PHENYL-CARBI.

NOL C, H18O i.e. CHPh(OH).C, H2Me, Phenylmesitylene carbinol. [34°]. (330°). Formed by reducing benzoyl-mesitylene with sodium-amalgam (Louise, Bl. [2] 45, 231; A. Ch. [6] 6,

209). Prisms. Boiling diluted H₂SO₄ (1:1) converts it into (C₁₀H₁)₁₀O [137°].

Ethyl ether O₁₀H₁EtO. [32°]. Prisms.

Acetyl derivative O₁₀H₁A,AcO. [52°].

Benzoyl derivative. [94°]. Crystals.

Benzoyt derivative. [947]. Crystals.
DIPHENYL TRIMETHYLPHENYLENE DIRETONE (C.H., CO), C.H.Me. [1177]. Formed
by heating C.H., CO.C.H.Me. with BzCl and
AlCl. (Louise, C. R. 98, 151; A. Ch. [6] 6, 236). Prisms, sol. alcohol and ether.

Di-phenyl tetramethylphenylene diketone C.Me.(CO.C.H.). [270°]. A product of the action of BzCl and AlCl, on durene (Friedel a. Crafts, C. R. 88, 880). Minute prisms, sol. benzene, almost insol. boiling alcohol. PHENYL METHYLPHENYL KETONE v.

PHENYL TOLYL RETONE.

Phenyl dimethylphenyl ketone v. PHENYL XYLYL RETONE.

Phenyl trimethylphenyl ketone

C₂T₄,CO₂CO₄H,Me₃[1:2:4:6]. Benzoyl-mesitylene, Phenyl mesityl ketone. [35°]. (319°). V.D. 8·18. Formed from BzOl, mesitylene, CS₂, and AlCl. (Elbs, J. pr. [2] 35, 485; cf. Louise, A. Ch. [6] 6, 200; C. R. 96, 499; Claus, B. 19, 2879). Prisms (from alcohol), sol. acetone and ligroin.

Does not react with hydroxylamine (Smith, B. 84, 4052).

Reactions .- 1. Conc. H2SO, or H2S2O, 100° gives benkoic acid and mesitylene sulphonic acid.—2. Conc. H,SO, at 50° forms phenyl-mesityl-ketone sulphonic acid C_{1s}H_{1s}O.SO_sH.—8. A mixture of fuming HNO_s and H,S₂O, forms two trinitro-derivatives [188°] and [145°]. 4. HNO, (S.G. 1.1) at 200° forms benzoyl-uvitic or phenyl-tolyl-ketone dicarboxylic acid.--5.

Potash-fusion gives mesitylene and KOBs .-- 6. HI reduces it to benzyl-mesitylene.-7. Sodiumamalgam yields the carbinol .- 8. Chromic acid oxidises it to C.H.CO.C.H.Me.CO.H.

Phenyl tetra-methyl-phenyl ketone C₄H, CO.C, HMe, [119⁴]. (343°) Formed by heating durene with BzCl and AlCl, at 120° (Friedel, Crafts, a. Ador, C. R. 88, 980). Crystalline. Decomposed by potach-fusion into benzoic acid and durene. Reduced by HIAq

and P at 240° to CH.Ph.C.HMe, [60.5°], (310°).

Romeride C.H., CO.C.HMe, [63°], (300°).

Formed from BzCl and isodurene (got from a toluene, McCl, and AlCl₂). Crystals (Essner a.

Gossin, Bl. [2] 42, 171) PHENYL TRIMETHYLPHENYL KETONE o-CARBOXYLIC ACID C.H.Me., CO.C.H., CO.H. [212°]. Formed from phthalic anhydride, mesitylene, and AlCl. (F. Meyer ac Gresly, B. 15, 639; A. 234, 234). Needles (from alcohol). Phenyl tetramethylehenyl ketone carboxylic

acid v. Tetra-methyl-benzoyl-benzoic acid.

PHENYL - TRIMETHYLPHENYL - THIO-UREA NHPh.CS.NHC, H.Me,. [193°]. Formed by heating methyl-thiocarbimide with an alcoholic solution of aniline (Eisenberg, B. 15, 1014). PHENYL-DI-METHYL-PHOSPHINE

PMe₂Ph. (192° cor.). S.G. ¹¹ 977. Formed from POl₂Ph and ZnMe₂ in benzene (Michaelis, A. 181, 359). Liquid, oxidised by air. Combines with CS₂ forming PMe₂PhCS₂ crystallising in red plates and yielding B'2H2PtCl4 (Czimatis, B. 15, 2017).

Salts.—B'HCl: crystalline, sl. sol. ether, v. e. sol. alcohol.—B'2HCl. Liquid.—B'2HLPtCl.

Methylo-iodide PMe, PhI. [205°]. Bromo-ethylo-bromide

PMe₂Ph(O₂H₄Br)Br. [173°]. Formed from PMe₂Ph and C₂H₄Br₂ (Gleichmann, B. 15, 199). PMe, In and c. II. pr. (criecumann, B. 10, 1891, Vicids (B'(C,H,Br)Br), PtCl, and the unstable B'C,H,Br. An alcohole solution of phenyl-di-methyl-phosphine forms (PMe,Ph),C,H,Br. [above 300], S. (alcohol) 2 at 21°, which gives unstable (FMe,Ph),C,H,Br. [171°].

Di-phenyl-methyl-phosphine PMePh. (284°).

S.C. 12 1°08. Formed from PCIPh, and ZnMe, Wichesies, Link 4 207 210). Liquid Vicids

S.G. 12 108. Formed from PGIFA, and ZnMo, (Michaelis a. Link, A. 207, 210). Liquid. Yields PMe,Ph.J. [241°], 4PMe,Ph.J.PtCl, [218°], and PMcPh.O [112°] (Michaelis a. La Coste, B. 18, 2116; A. 229, 316).

PHENYL-DI-METHYL-PHOSPHINE p-CARBOXYLIC ACID C₈H₄(CO,H).PMe,The methylo-chloride C₈H₄(CO,H).PMe,Cl, formed the cidelic of the methylo-chloride to a cidelic of the cidelic of the methylo-chloride to a cidelic of the cidelic of th by oxidation of the methylo-chloride of p-tolyldi-methyl-phosphine, crystallises in prisms di-metalyi-phosphine, crystallises in prisms (Michaelis, B. 15, 2018). It yields the compounds B'Me,PtCl₂, C,H₁(CO₂H).PMe₃OH 2aq, and C₄H₄(CO₂H).PMe₃SO₄H.

Oxide C₄H₄(CO₂H).POMe₂. [243°]. Formed

by oxidation of the ethyleno-bromide of tolyl-di-methyl-phosphine. Colourless prisms.

PHENYL METHYL PROPYLENE DI-

PHENYL MEHILL FROM LINES EXECUTED TO SERVICE CO.CH. (265°-270°). Formed from benzoyl-acetone, N., and Etl (Claisen a. Lowman, B. 21, 1152). Liquid. PHENYL - METHYL-PROPYLENE-y-THIO-

UREA CHMe.S CNPhMe. (c. 800°). Formed by heating methyl-aniline with allyl thiocarb-imide and HClAq at 100° (Prager, B, 22, 2096), —B',H,PtCl, [184°].—B'C,H,N,O, [125°].

TRI.PHENYL-METHYL.PROPYL-DI.THIO-BIURET C'S, N, Ph, MePr. [110°]. Formed from NPhMetCSCl and di-phenyl-propyl-thio-urea Rilleter a. Strohl, B. 21, 109). Small yellow pyramids. An isomeride [111°] is formed from NPhPr.CSCl and di-phenyl-methyl-thio-urea.

DI - PHENYL - METHYL - PROPYL - THIO-URBA NPhMe.CS.NPhPr. [56°]. Formed from CSCl., propyl-apiline, and MeCl or from CSCl., methyl-aniline, and PrCl (Billeter a. Strohl, B. 21, 103). Colourless prisms.

DI-PHENYL-DI-METHYL-PYRAZINE . $CMe \leqslant_{CPh,N}^{N:CPh} \geqslant_{CMe.} [124^{\circ}].$ Formed when phenyl amido-ethyl ketone is allowed to stand with NH, Aq (Schmidt, B. 22, 3253).—B'HCl: needles.—B',H,PtCl.

Di-phehyl methyl pyrazine-dihydride

N CPh.CPh N. [112°]. Formed from benzil and propylene-diamine (Strache, B. 21, 2363). Needles, v. sol. benzene; m. sol. alcohol.

Di-phenyl-tetra-methyl-pyrazine dihydride

C.,H.,N. i.e. NPh CMe:CMe NPh. (281°). Formed by heating \$\beta\$-bromo-\$-acetylpropionic acid (1 pt.) with aniline (3 pts.) at 95°; the yield being 70 p.c. of the theoretical amount (Wolff, B. 20, 429). Satiny plates, v. sol. ether and conc. HClAq.

References .- NITRO- and OXY-DI-PHENYL-METHYL-PYRAZINE.

PHENYL-METHYL-PYRAZOLE

NPh<\(\frac{N=CMe}{CH:CH}\). [37°]. (255°). S.G. 12 1 085.

Formation .- 1. By heating oxy-phenylmethyl-pyrazole NPh N=CMe with zinc-dust (Knorr, A. 238, 199).—2. From acetoacetic aldehyde, phenyl-hydrazine, and HOAs (Claisen, B. 21, 1147; 24, 1888).—3. By heating its carboxylic acid at 210° (Ach A. 253, 55).—4. From

oxy-phenyl-methyl-pyrazole dihydride and P₂S₂ (Knorr a. Duden, B₂S₂, 766).

Properties.—Needles, v. sol. alcohol and ether; volatile with steam. Oxidised by KMnO₄ to phenyl-pyrazole carboxylic acids [146°].

Salt .- B'H.PtCl : orange needles.

NPh CH2 CH2 [759]. Dihudrida Formed by reducing the base in alcoholic solution with Na. Flat needles, m. sol. alcohol.

Phenyl-methyl-pyrazole NPh CMe;CH (262°). Formed by distilling its dicarboxylic acid (Knorr a. Laubmann, B. 22, 178). Got also from acetone, oxalic acid, and phenylhydrazine (Claisen a. Roosen, B. 24, 1890). Yields phenyl-pyrazole carboxylic acid [183°] on oxidation by KMnO₄.—B'₂H_PtCl₂ 2aq. [147°].

Phenyl-di-methyl-pyrazole

NPh N= CM (273° i.V.). Formed by heating its carboxylic acid (Knorr, B. 20, 1103) and by warming acetyl-acetone with phenyl-hydrazine (K.; Combes, Bl. [2] 50, 145). Oil, volatile with steam. -B', H, PtCl, 4aq. Decomposes at 186°.

Methyle-iodide B'MeI. [190°]. Crystals, v. sol.swater.—B',Me,PtCl,. Decomposes at 220°.

Dihydride NPh CHMe.CH₂. (290° i.V.). Formed by adding Na to a boiling alcoholic solution of the base.

Phenyl-tri-methyl-pyrazole. Dihydride NPh CMe, CH2. Formed by heating mesityl oxide with phenyl hydrazine (Fischer a. Knoevenagel, A. 239, 203). Oil, v. e. sol. ether and alcohol, sl. sol. water. Its solution in dilute HCl gives a violet colour with K₂Cr₂O₁,—B'₂H₂PtCl₂: crystalline pp.

Di-phenyl-methyl-pyrazole CieH, Ne i.e. NPh CM x CH . [63°]. (335° or 355°). Formed by heating its carboaylic acid at 250°, and also by warming ben toyl-acetone with phenyl-hydraz-ine (Knorr, B. 18, 314; Fischer, B. 18, 2185). Insol. water, v. sol. alcohol. Weak base. Yields C_{1c}H₁ BrO₂ [75°]. — B'₂H₂PtCl_a aq. — B'MeI. [187'].—B'₂M₂PtCl_a. [241°]. Orange-red needles. Dihydride C₁₆H₁₆N₂. [109°]. Long prisms (from ether). Its acid solution is coloured in-

Di-phenyl-methyl-pyrazole C.H.N. NPh CH CPh:CMe. [47°]. (365°). Formed by heating its carboxylic acid, and also, together with its dihydride, by distilling the phenylhydraxide of benzylidene-acetone (Knorr, B. 18, 931; 20, 1100). Weak base.—B'_zH_PtCl_: red prisms.—B'MeI. [192°].—B'_Me_PtCl_. [229°].

Dihydride C_iH_iR_. [114°]. (c. 850°). Prisms. Its solutions fluoresce blue and give a blue colour with nitrous acid.

tensely red by nitrous acid.

Tri - phenyl - methyl-pyrazole. Tetrahydride NPh NMe CHPh. [110°]. Formed by the action of Na and boiling alcohol on triphenyl-pyrazole methylo-iodide (Knorr a. Laubmann, B. 21, 1205). Insol. water, v. sol. alcohol. Resinatied by conc. HNO.

References .- Oxy-AMIDO- and Oxy-PHENYL-

METHYL-PYRAZOLE:

PHENYL - METHYL . PYRAZOLE CARB-OXYLIC ACID NPh CMe:CH Formed from acetone, oxalic acid, and phenyl

hydrazine (Claisen a. Roosen, B. 24, 1891).

Methylether MeA'. (256° at 109 mm.). Amide. [146°].

OXYLIC ACID C_{1,1}H₁,NO₄ i.e. CO₂H₁C₄H₂CCHCH: CMe (CO₂H).C CO₂C(CO₂H):N [201°]. Formed by oxidising methyl·(β) -naphthoquinoline by KMnO₄ in acid solution (F. Scitz, B. 22, CO²C). No allow (contribing an incomplete contribing and contribution and contribut 257). Needles (containing aq) or anhydrous prisms. FeSO₄ colours its aqueous solution lemon-yellow. — Na₂A" 2aq. — ZnA" 1½aq. — CuA" 1 aq: minute bluish-green plates.

Phenyl-di-methyl-pyridine carboxylic acid N CMe:C(CO,H) CPh. [190°]. Got from its ether, which is formed by heating the mono-ethyl ether of the dicarboxylic acid (Hantzsch, B. 17, 2911). Small prisms (containing 2aq), v. Bol. hot water.—CuA'₂.—(HA'),H,PtCl, aq.

Ethyl ether EtA'. (316°-320°). Thick
liquid. Yields (EtA'),H,PtCl, [196°] and also

EtA'MeI [c. 206°], which is converted by alcoholic potash into C₁₅H₁₅NO, [161°], split up by HClAq at 180° into acetic acid and oxy-phenyldi-methyl-pyridine [112°].

Phenyl-di-methyl-pyridine dicarboxylic acid

 $N \leqslant_{CMe.C(CO_2H)}^{CMe.C(CO_2H)} \geqslant_{CPh}$.

Mono-ethyl HEtA". ether Formed by boiling the di-ethyl other with alcoholic KOH (1 mol.) (H.). Cubes (from alcohol). Di-ethyl ether Et.A". [67°]. Formed

by exidising its dihydride with nitrous acid. Dihydride of the di-ethyl ether

N CHMe. CH(CO,Et) CPh. [157°]. Formed by heating a mixture of benzoic aldehyde, acetoacetic ether, and alcoholic NH₃ (Schiff, a. Puliti, B. 16, 1607; Bally, B. 20, 2591). Formed also by mixing benzylidenc-acetoacetic ether with β imido-butyric ether (Beyer, B. 24, 1666). Colourless crystals, sol. acohol.

(β)-Phenyl-di-methyl-pyridine dicarboxylic

Formed by oxidising di-methyl-(\$)-naphthoquinoline with KMnO, (Recd, J. pr. [2] 35, 311). Syrup.—AgA'.

Reference. -- OXY-PHENYL-DI-METHYL-PYRIDINE CARBOXYLIC ACID.

PHENYLTRI METHYL PYRIDYL KETONE CARBOXYLIC ETHER

N < CMe.C(CO.Et) > CMe. Formed by the action of nitrous acid on its dihydride. - B'HNO: white plates. — B'HCl. [192°]. Prisms. — B'2H2PtCl8: needles.

Dihydride NH CMe:C(CO,Et) CHMe.

[187°]. Formed from ethylidene-acetoacetic ether and C.H., CO.CH., C(NH).CH, (Beyer, B. 24, 1667). Yellowish plates.

Methyl derwative of the dihydride NMe<CMe:C(CO.Et)>CHMb. [87°] Formed, in like manner, by the action of the methylimide of benzoyl-acetone on ethylidene-acetoacetic ether (B.). Yellowish-white needles, RHENYL-METHYL-PYRIMIDINE C11H16N2

i.e. CPh N.CMe CH. [74°-78°]. Formed by distilling the oxy-derivative (from benzamidine and acetoacetic ether) with zinc-dust (Pinner, B. 18, 2850). Colourless needles.—B'2H2Cl2PtCl4. [190°].

References .- OXY- and OXY-ANIDO-PHENYL-METHYL PYRIMIDINE.

PHENYL-METHYL-PYRROLE C,H,N i.e. NH CMe: CH. [101°]. Got by heating acetophenone-acetone CH_Bz.CH_Ac with alcoholic NH, at 150°; the yield being 30 p.c. of the theoretical (Paal, B. 18, 367). Plates, v. sol. alcohol. May be sublimed. Gives a purple-red colour with isatin and H.SO.

Phenyl-di-methyl-pyrrole C.H .. N i.e. NPh CMe.CH. [52°]. (252°). Formed by distilling its dicarboxylic acid at 2448 (Knorr, 4. 236, 306).

DI-PHENYL-METRYL-PYRROLE $C_{i_7}H_{i_8}N$ NPh CMe: OH. [84]. Formed by heating the broxylic acid [226°] to above its melting-point dederer a. Paal, B. 18, 2596). Large tables. Tetra-phenyl-methyl-pyrrole

Me CPh:CPh [214°]. Formed by heating idesyl C, H, O, [255°] with aqueous methylmine at 150° (Fehrlin, B. 22, 554). Groups of sinute needles, sol. hot alcohol and ether.

Reference. - OXY - TM - PHENYL - METHYL - PYR-OLE. PHENYL-METHYL-PYRROLE CARBOXY-

IC ACID NH CMe:C.CO.H. [c. 190°]. Got y saponification of its ether, which is formed allowing acctophenone acctoacetic ether to tand with excess of NH, Aq (Lederer a. Paal, B. 18, 2593). Flat needles (from HOAc).

Ethylether Eth'. [120°]. Needles. Phenyl-di-methyl-pyrrole carboxylic ether Ch:H17NO2 i.e. NMe CMe:C.CO2Et Formed from acetophenone acetoacetic ether and NMeHAq (L. a. P.). Plates (from alcohol-

other), v. e. sol. alcohol.

Phenyl-di-methyl-pyrrole m-carboxylic acid CO₂H.C₆H₄.N CMe:CH [135°]. Formed by heating acetonyl-acetone with m-amido-benzoic

seid and alcohol (Paal, B. 19, 558). Flat crystals, sl. sol. water, v. sol. alcohol. Phenyl-di-methyl-pyrrole di-carboxylic acid

CO₂H.CH₂N<CMc:C.CO₂H [152°]. Got by saponifying its ether. Small needles (from alcohol), sl. sol. water.

Ethyl ether Et. A". [131°]: Got by allowing acetophenone-acetoacetic ether to stand with Plycocoll and HOAc (Paal a. Schneider, B. 19, 3160). Needles (from HOAc), sl. sol. water.

Phenyl di methyl pyrrole dicarboxylic acid NPh CMe:C.CO.H Gotfrom its ether. Powder, CMc:CAU_II

decomposing at 224° into CO₂ and phenyl-dimethyl-pyrrole.—CaA".—CaII,A"₂: prisms.

Ethyl ether Et₂A". [38°]. (280°) at 500 mm. Formed by warming di-acetyl-succinic mathematical and the color of t ether with aniline and HOAc (Knorr, A. 236, 805). Crystals.

Di-phenyl-methyl-pyrrole carboxylic acid NPh CPh:CH CMe:C.CO₂H [226°]. Obtained saponification of its ether, which is formed by boiling acetophenone-aceto-acetic ether with an

acetic acid solution of aniline (Lederer a. Paal, B. 18. 2595). Small needles (from acetic acid).

Ethyl ether A'Et: [100°]; prisms.

Di-phenyl-methyl-pyrrole di-o-carboxylio acid NMe C(C,H,CO,H):CH [231°]. Formed from C,H,(CO,C,H,CO,H), and methylamine in legals at 1009 (Bangang P 90 1489). Doop alcohol at 100° (Baumann, B. 20, 1489). Deepyellow plates, insol. water, sl. sol. ether.

Di-phenyl-methyl-pyrrole dicarboxylic acid CO₂H.C₆H._NCCMe.C.CO₂H. [210°]. Formed by saponifying its ether, which is got from acetophemone-acetoacetic ether, m-amido-benzoic acid, and HOAc (Paal a. Schneider, B. 19. 8162). Needles (from dilute alcohol).

Ethyl ether EtA'. [160°]. Needles. Reference. - OXY . PHENYL . METHYL . PYRROLM CARBOXYLIC ACID.

PHENYL-METHYL-QUINAZOLINE DIHY-

DRIDE C₁₅H₁₄N₂ i.e. C₈H₄ < N - CMo Formed by reduction of the acetyl derivative of o-nitro-benzyl-aniline with tin and HClAq (Paul a. Krecke, B. 23, 2638). Rosettes of white needles, insol. water, m. sol. ligroin. The tin double chloride melts at 122°.—B'HCl 2aq. [257°].—B'₂H.PtCl₂. Flat orange needles. Decomposes at 223°.

Reference.—Oxy - PIERNYL - METHYL - QUINAZ-

OLINE.

(Py. 1,3) - Phenyl-Methyl-Quinoline C.H. CPh:CH [100°]. Formed by boiling an alcoholic solution of o-amido-benzophenone with acctone and KOHAq (Geigy a. Königs, B. 18, 2406; 19, 2428). Obtained also from paraldehyde, acetophenone, HCl, and aniline, and by heating benzoyl-acetone-anilide C₁H₁NO with H₁SO₄ on the water-bath (Beyer, *J. pr.* [2] 33, 420; *B.* 20, 1771). Tables (from ether).—B'ILSO₄. [236°].—B'₂H₂PtCl₃2aq. [225°]. Its acid solutions fluoresce blue. By heating with phthalic anhydride and ZnCl, at 150° it is converted into the phthalone C2,H1,NO, [270] which crystallises from alcohol or HOAc in spaningly-soluble orange-red crystals.

(Py. 3,1)-Phenyl-methyl-quinoline O, H, N i.e. C.H. CMe:CH Flavoline. [65°]. (374°). V.D. 7.7 (calc. 7.6). Formed by distilling flave-nol with zinc-dust. Prepared by adding a little dilute (10 p.c.) NaOHAq to a solution of equi-molecular quantities of o-amido-acetophenone and acctophenone, and then heating on the water-bath (Fischer, B. 15, 1503; 16, 68; 19, 1037). Thick tables. Yields flavaniline on nitration and reduction. Salts .- B'HCl 2aq.-B',H,PtCl,: reddish-yellow needles.-B'MeI. [1852] (Bernthsen a. Hess, B. 18, 34). Converted by KOHAq into a strongly alkaline solid 'methyl-flavolinium hydrate.'— B'₂Mc₂PtCl₂.

(Py. 3,2)-Phenyl-methyl-quinoline C.H. CH:CMe. [53°].. (above 300°). Formed by heating a mixture of CHPh:CMe.CHO, aniline, and conc. HClAq at 200° (Miller a. Kinkelin, B. 19, 527). Trimetric prisms, v. sol. alcohol and ether.—B',H,PtCl,: orange plates.-B'C,H,N,O,. [202°]. Large yellow plates.

(B. 2)-Phenyl-(Py. 4)-methyl-quinoline tetrahydride C16H1,N i.e. CPh:CH.C.CH2 .CH. CH.C.NMe.CH2 Formed by reducing (B. 2)-phenyl-quinoline methylo-chloride with tin and HClAq (La Coste a. Sorger, A. 230, 24. Amorphous powder, insol. cold water.—B'HCl.—B'HI.—B'G.H.N.O., [147°].—B'McI aq. [195°]. Yellow Pates. (Py. 3)-Phenyl-(B. 4)-methyl-quinoline CH:CH. (C.CH:CH.

CH:CMe.C.N=CPh. [50°]. Formed by distilling its (Py. 1)-carboxylic acid with soda-lime (Doebner a. Giesecke, A. 242, 299). Plates (from alcohol).—B'2H_PtCl_s. Brick-red needles. (Py. 3)-Phenyl (B. 2)-methyl-quinoline CMe:CH:CCH:CH [68°]. (above 360°). Got by distilling its carboxylic acid with soda-lime (D. a. C.). Small yellow needles (from cilute alcohol).—B'_H_PtCl_a: golden needles.

References.—Nitro-and Oxy-PHENYL-METHYL-

QUINOLINE.

(Py. 3)-PHENYL-(B. 4)-METHYL-QUINOL-INE (Py. 1)-CARBOXYLIO ACID C.H., NO., [245°]. Formed by heating equi-molecular proportions of o-toluidine, benzon aldehyde, and pyruvic acid in alcoholic solution on the waterbath (Doebner a. Giesecke, 4. 242, 298). Small yellow crystals (from alcohol), w. sl. sol. hot water.—CuA', aq.—AgAbaq: needles (from Aq).

bath (Doebner a. tiesecke, A. 222, 239). Smain yellow crystals (from alcohol), w. sl. sol. hot water.—CuA'₂aq.—AgAsaq: needles (from Aq). (Py. 3)-Phenyl. (B. 2)-methyl-quinoline (Py. 1)-carboxylic acid. [228°]. Formed in like manner from p-toluidine (D. a. G.). Yellow needles (from alcohol).—CuA'₂.—PbA'₃.—AgA'.
—H₂A'₂H.PtCl_n: golden needles, v. sl. sol. hot Aq. Reference.—Oxy-phenyl. Methyl. -Quinolyne

CARBOXYLIC ACID.

PHENYL (Py. 8)-METHYL-(B. 2)-QUIN-OLYL RETONE C₆H₄.CO.C₆H₃< $\stackrel{\text{CH:CH}}{N}$ = $\stackrel{\text{CM:CM}}{CM}$? [68°].

(above 300°). Formed from anido-benzophenone, paraldehyde, and HClAq at 100° (Hinz, A. 242, \$23). Needles (from water) or plates (from alcohol).—B'₂H₂PtCl₂ 2nq.—B'₂H₂Cr₂O,.—B'MeI. [220°]. Small dark-green needles; v. sol. water.

Phenyl (Py. 3)-methyl-(B. 4)-quinolyl ketone. [108]. Formed by boiling o-amido-benzophenone with dilute II,SO, and paraldelyde (Geigy a. Königs, B. 18, 2406). Matted needles (from dilute alcohol).

PHENYL DI - METHYL QUINOLYL THIO-UREA NHPh.CS.NH.C₁₁H₁₀N. [159°]. Formod by heating phenyl-thiocarbimide with amido-dimethyl-quinoline (Marckwald, B. 23, 1025). Prisms, v. sol. hot alcohol.—B'₂H₂PtCl₄: pp.

PHENYL-METHYL-QUINOXALINE
CM::CH.CN.CII· [79°]. Formed by reducing
C₂H,Me(NO₂).NH.CH₂Bz with SnCl₂ and HCl
(Lellmann a. Donner, B. 23, 171). Needles, v.
sol. alcohol.—B'HgCl₂. [223°]. White needles.
Phenyl-methyl-quinoxaline

CMe:CH. c.N:CH. [135°]. Formed, together with the preceding isomeride, by the action of chloroacetophenone on tolylene-o-diamine (Hinsberg, A. 237, 370). Formed also by warming phenylglyoxylic aldehyde C.H., CO.CHO with tolylene-o-diamine sulphate and NaOAc (Pechmann, B. 20, 2905). Needles, v. sol. hot alcohol and ether. Phenyl-di-methyl-quinoxaline

 $C_{\rm e}H_{\rm a}{\rm Me} < {
m N:CMe \over
m N:CPh}.$ [48°]. Formed by boiling phenyl methyl diketone with tolylene-o-diamine in ether (Müller a. Pechmann, B. 22, 2130). V. sol. most solvents.

Di-phenyl-methyl-quinoxaline $C_{n}H_{1k}N_{2}$ i.e. $C_{s}H_{s}Me < \stackrel{N:CPh}{N:CPh}$ [111°]. Formed by heating benzil with tolylene-o-diamine in alcoholic solution (Hinsberg, B. 17, 322). Silvery plates. May be distilled. Weak base. Nearly insol. Aq.

Di-phenyl-v-methyl-quinoxaline dihydride

OpH Ne. CPHh. [133°]. Formed by heating

phenylene-methyl-o-diamune with benzoln at 165° (Fischer a. Busch, B. 24, 2682). Yellow needles, m. sol. alcohol. Its solutions fluoresca greenish-yellow.

Reference. — OXY - PHENYL - METHYL - QUIN-

PHENYL-METHYL-ROSINDULINE

C₁₀H_s(NPh) \ll NPh C₄H₂Me $\left[\frac{1}{2}4\right]$. [232°]. Formed from benzene-azo-p-tolyl-(a)-naphthylathine (Fischer a. Hepp, A. 256, 243). Reddishbrown bronzed plates. Split up by conc. HClA₁ at 200° into an line and methyl-rosindone.

PHENYL-METHYL-SUCCINIC ACID

PHENYL-PYROTARTARIC ACID.

Phenyl-tri-methyl-succinic acid C₁₃H₁₆O, i.e. CH₂Ph.CH(CO₂H).CMe₂.CO₂H. [140°]. Formed from bramo-isgbutyric ether and sodium benzyl-malonic ether, the resulting ether (200°-220') being saponified (Bischoff, B. 24, 1060). Short needles (from water), v. sol. alcohol and ether.

needles (from watca), v. sol. alcohol and ether.
Di-phenyl-di-methyl-succinic acid. Nitrile
CPhMe(CN).CPhMe.CN. [227°]. Formed from
CITPhMe.CN by treatment with NaOEt and I
(Chalanay a. Knoevenagel, B. 25, 289). Insol.

benzene, sl. sol. alcohol.

PHENYL-METHYL-SULPHAMIC ACID

NPhMe.SO,H. Formed from CISO,H and methyl-aniline in chloroform (Traube, B. 24, 362).—NH,A'. Turns violet in air. Decomposed by boiling HClAq into methyl-aniline and H,SO,. The potassium salt is a crystalline powder, sl. sol. alcohol, v. sol. water.

PHENYL-DI.METHYL SULPHAMIDE SO₂(NMe₂)(NHPh). [85°]. Formed from NMe_SO₂(2 and aniline (Behrend, 4. 222, 128). Needles (from ether). Yields SO₂(NMe₂)(NPhNa)

crystallising in needles, v. sol. water and alcohol.

PHENYL METHYL SULPHIDE PhSMe.
(188°). Formed from Pb(SPh), and MoI at 100°

(Obermeyer, B. 20, 2926). Liquid.
PHENYL METHYL ESULPHONE C.H.SO. i.e.
C.H.SO.CH. [89]. Formed from benzene
sulphinic acid, NaOEt, and MeI at 100°, and
also by boiling C.H., SO.CH., CO.H with alcoholic potash (Michael a. Palmer, Am. 6, 251;
7, 65; Otto a. Bössing, B. 18, 156; 21, 652;
22, 1449, 1452, 23, 755). Plates (from hot water),
v. e. sol. alcohol and ether.

PHENYL METHYL SULPHONE ω-CARB-OXYLIC ACID υ. PHENYL-SULPHONO-ACETIC ACID.

PHENYL-METHYL-THIAZOLE C₁₀H₄NS i.e. NCMe:CH. (279° cor.). Formed from thiobenzamide and chloro-acctone in alcohol (Hubacher, A. 259, 236). Oil.

Phenyl-methyl-thiazole N CPh:CH. GMs.S [68:5°]. (284° cor.). Formed from thioacetamide and w-bromo-acetophenone (Hantzsch, B. 21, 913; A. 250, 269). Weak base. Not attacked in boiling alcoholic solution by sodium (Sohatzmann, A. 261, 7).—*B'HCl: sl. sol. Aq.

Phenyl-methyl-thiazole. Dihydride
NCH,CHMe. Formed by boiling propylene
bromide with thiobenzamide (Gabriel a. Heymann, B. 24, 785). Yellowish liquid.—Picrate
B'CeH,N₂O₁: crystalline.

Di-phenyl-methyl-thiasole N CPh:CPh

Pol. Formed from thioacetamide and bromooxybenzoin in alcohol (Hubacher, A. 259, 4). Stellate groups of needles, insol. water. Hydrochloride: [97°]; white crystals from dilute HClAq).

PHENYL-METHYL-THIAZOLE CARBOXY-FIC ACID N CMe;C.CO,H. [203°]. Formed

y saponifying its ether. Needles, sl. sol. ether. Ethyl ether Eth'. [43°]. Formed from hiobenzamide and chloro-acetic ether (Hubacher,

PHENYL (a) METHYL-THIENYL KETONE H., CO.C. H. MeS. [124°]. Formedby heating O,H,Me(HgCl)S with BzCl at 100° (Volhard, A. 267, 181; cf. Ernst, B. 19, 3280). Needles (fromligroin).

TRÍ - PHENYL - DI - METHYL - DI-THIO-BIURET C.,H.,N.S., i.e. NPh(CS.NPhMe), or CS(NPhMe).S.C(NPh)(NPhMe). [202°]. Formed from Cl.CS.NPhMe and aniline (Billeter a. Strohl, B. 21, 10s). Needles, v. sl. sol. cold alcohol.

PHENYLA METHYL . DI-THIO-CARBAMIC ACID NPhMe.CS.SMe. '882]. Formed by heating NPhMc.C(NMc).SMc or NPhMc.C(NH).SMc with CS at 160° (Bertram,

B. 25, 51). Plates.
PHENYL - METHYL - THIOCARBAMIC CHLORIDE NPhMe.CS.Cl. [35"]. Formed from methyl-aniline and CSCl₂ (Billeter, B. 20, 1631). Yellowish crystals. Converted by alco-· hol into (NPhMe.CS).O [116.5].

PHENYL . METHYL-THIO-SEMI-CARBAZ-IDE NHPh.NH.CS.NHMe. [89°]. Formed from methyl-thiocarbimide and phenyl-hydrazine (Dixon, C. J. 57, 262). Trimetric prisms, v. sl. sol. cold water. H2SO, forms an azure-blue solution. CuSO, gives a deep-blue colour, and FeCl, a greenish-blue.

Phenyl-methyl-thio-somi-carba#de

NHPh.CS.NII.NHMe. [143°]. Formed from methyl-hydrazine and phenyl-thiocarbimide (Brüning, A. 253, 11). Prisms (from alcohol).

Di-phensl-methyl-thio-semi-carbazide

NPhMe.NH.CS.NHPh. [154°]. Formed from phenyl-methyl-hydrazine and phenyl-thiocarb-imide (Fischer, A. 190, 166). V sol. hot alcohol. PHENYL-METHYL-THIOCARBIZINE

CS NPh. [123°]. Formed from phenyl-thiocarbizine and MeI at 100° (Fischer, A. 212, 330). Tables (from water). Not attacked by nitrous acid.

PHENYL-METHYL-THIOHYDANTOIC ACID NHPh.CS.NH.CHMe.CO.H. Formed alanine and phenyl-thiocarbinide in alcohol (Marckwald, B. 21, 3280; cf. Aschan, B. 17, 421).- KA': minute needles.

PHENYL-METHYL-THIOHYDANTOIN

CS<NPh,CO NH-CHMe. [184°]. Formed by treating phenyl-methyl-hiohydantoïc acid (v. supra) with HCl. Small prisms (from alcohol). Split up by HClAq at 150° into aniline, alanine, CO.,

Phenyl-di-methyl-thiohydantoin

CS NPh.CO [673]. Formed from phenylthiocarbimide and α-amido-isobutyric acid (Marckwald, B. 21, 3282) Crystals, sl. sol. Aq. Vol. IV.

PHENYL-METHYL-THIOPHENE C., II., S i.e. S CMe: CH. [51°]. (271° uncor.). Got by heating acetophenone-acetone with P.S. at 1250 the yield being 70 p.c. of the theoretical amount (Paal, B. 18, 367). Needles, volatile with steam. Gives the indophenine reaction.

S<CMe:CH :CPh. Phenyl-methyl-thiophene [73°]. Formed by heating CH.Ac.CHPh.CO.Na with P.S. or P.S. (Paul a. Püschel, B. 20, 2558). Piates, • sol. bot alcohol. Gives the indophenine reaction on warming. Br forms C, H, Br, S

s-PHENYL-METHYL-THIO-UREA C,II, N.S i.e. CS(NHPh)(NHMe). [133]. Formed from methyl-thiocarbimide and aniline (Gebhardt, B. 17, 3038). Six-sided tables. Yields NH, Me and CS(NHPh), on boiling with aniline.

u-Phenyl-methyl-thio-urea

CS(NIP)(NPhMo). [107°]. Formed from methylaniline hydrochloride and potassium sulphocyanide (Gebhardt, B. 17, 2094). Tables (from alcohol) or prisms (from hot water).

Phenyl-methyl-\psi-thio-urea
Mes.G(NII)(NIIPh). [71°]. Formed by warming phenyl-thio-urea with MeI and alcohol (Bertram, B. 25, 49). Colourless crystals, sl. sol. hot water. Converted by dilute H.SO, at 160° into MeS.CO.NHPh. - B'HI. [147°].— B'H.SO., [171°].—B'.H.SO., [171°].—B'.HNO., [113°].—B'.HO.do. [115°].—B'., H.PtCl., [184°].—B'.G.H.,(NO.),3OH. [175°]. Yellow plates. Phenyl-di-methyl-thio-urea

CS(NHMe)(NPhMe). [114°]. Formed from methyl-thiocarbimide and methyl-aniline (G.).

Phonyl-di-methyl-\psi-thio-urea MeS.C(NH)(NPhMe). Formed from phenylmethyl-\psi-thio-urea and methyl iodide (B.).
Oil. Converted by dilute H.SO, at 160° into [184°]. -MeS.CO.NPhMe [54°]. — BHI. B'C_sH_aN₃O₃. Small prisms.

Phenyl-tri-mothyl-4-thio-urea C. H. N.S i.e. MeS.C(NMe)(NPhMe). Methyl-imido-methylphenyl-carbamic thiic methyl ether. Formed by methylation of phenyl-di-methyl-+thio-urea (B.). -B'HI. [c. 184]. $-B'_2H_2PtCl_{g}$. [c. 174]. $-B'C_6H_3N_3O$. [126]. Lemon-yellow crystals.

Di-phenyl-methyl-thio-urca CS(NIIPh/(NPhMe), [87°], (205°). Formed from phenyl-thiocarbimide and methyl-aniline Prisms, v. sol. hot alcohol. Decomposed into the parent substances by distillation with steam. Boiling aniline yields CS(NHPh), and methyl-aniline.

Di-phenyl-methyl- ψ -thio-urea

MeS.C(NPh)(NHPh). [110°]. Formed from CS(NHPh), and MeI. Conc. HClAq at 150° Formed from yields aniline and methyl-mercaptan. -B'HI.

Di-phenyl-di-methyl-thio-urea CS(NPhMe), [72.5]. Formed from NPhMe.CS.Cl and methylaniline (Billeter, B. 20, 1631). Prisms (from ligroïn).

Di-phenyl-di-methyl-ψ-thio-ures MeS.C(NPh)(NPhMe). (above 300°). Formed from CS(NHPh)(NPhMe) and MeI (Bertram, B. 25, 57). CS, at 160° forms NPhMe.CS, Me.—B'HI. Crystalline meal, sl. sol. hot water.

Reference. - OKY - DI - PHENYL - METHYL- 4-THIO-UHRA.

PHENYL-METHYL-UREA C,H,ON,O CO(NH₂)(NPhMe). [82°]. Formed from methylandline hydrochloride and potassium cyanate (Gebhardt, B. 17, 2095). Thin crystals.

Phenyl-di-methyl-ures CO(NMe2)(NPhMe). Formed from NMe, COCl and aniline (Michler a. Escherich, B. 12, 1163). Crystal's (from alcohol).

Di-phenyl-methyl-urea CO(NPhMe)(NIIPh). [104°]. (204°). Formed from phenyl cyanate and methyl-aniline (G.). Small needles

Di - phenyl - di - methyl-urea CO(NPhMe). [121°]. (c. 350°). Formed from NPhMe.COCI and methyl-aniline (Michler a. Zimmermann, B. 12, 1165). Tables (from alcohol) PHENYL-(B)-NAPHTHACRIDINE

 $C_{10}H_{\text{s}} < \stackrel{CPh}{\sim} C_{10}H_{\text{s}}. \quad \text{[297°]}. \quad \text{S. (alcohol)} \quad 04.$ at 15°; S. (benzene) 29 at 18°. Formed by heating a mixture of di-(B)-naphthylamine with BzCl or with benzoic acid and P2O5 or ZnCl2 (Claus a. Richter, B. 17, 1595; Ris, B. 17, 2029) Klopsch, B. 18, 1586). Needles, v. sol. hot benzene. B'HCl. B'₂H₂PlCl_a: yellow needles.

Dihydride O10H6<NII C10H0. Got from benzoic aldehyde (1 mol.) and (3)-naphthylamine (2 mols.) in presence of condensing agents (Claisen, A. 237, 273). Oxidised to phenyl-naphthacridine.

enyl-naphthacridine.
(8)-PHENYL-NAPHTHALENE $C_{1a}H_{12}$ i.e. (calc. 7.05). C₁₀H,C₄H₅. [102°]. V.D. 7·12 (calc. 7·05). Formed by passing a mixture of naphthalene and bromo-benzene through a red-hot tube (Watson Smith, B. 12, 2049; C. J. 39, 546; ('. J. Proc. 5, 70). Formed also by the action of H₂SO₄ (80 g.) diluted with water (44 g.) on CHPh(OH).CH₂OH (Zincke a. Breuer, A. 226, 23; 240, 137). Fluorescent plates. May be sublimed. Gives rise on oxidation to a quinone $C_{10}H_{10}O_2$ [110°].

A hydrocarbon C₁₆H₁₂ [104°] got by distilling chrysoquinone with soda-lime is perhaps identical with the above (Graebe, B. 6, 66; 7, 792; Schmidt, J. pr. [2] 9, 285).

(α)-Phenyl-naphthalene dihydride v. Atron-

Reference.—OXY-AMIDO-FHENYL-NAPHTHALENE.
DI-PHEÑYL-NAPHTHAMIDINE C₂₃H₁,N₂
C_{0.}H₁,C(NPh).NHPh. [183·5°]. Formed i.e. C₁₀H₇.C(NPh).NHPh. [183:5°]. from (a)-naphthoic acid, aniline, and PCl₃ (Bössneck, B. 16, 642). Needles (from alcohol).

PHENYL-(β)-NAPHTHINDOLE C₁₃II₁₃N i.e. C₁₀H_eCH CPh. [130°]. Formed by heating the (B)-naphthyl-hydrazide of acetophenone with ZnCl, at 170° (Ince, A. 253, 42). Crystals, v. sol. alcohol and ether. Colours pinewood green.—B'C₆H₃N₃O₇. [166°]. Brown needles.

Phenyl-(β)-naphthindole $C_{10}H_{a} < {\rm CPh \atop NH} > CH$. [211°]. Formed by the action of alcoholic HCl on the (3)-naphthyl-hydrazide of phenyl-acetic aldehyde (I.). Needles, suddenly decomposed on fusion. Colours pinewood green. ZnCl. at 170° converts it into the preceding isomeride.

-B'C₂H,N₂O₇. [120°]. Reddish-brown needles.

PHENYL-NAPHTHOTRIAZINE. Dihy-

dride C1,H1,N, i.e. C10H4 N.CH2 [184°]. amine with formic paraldeliyde at 140° (Goldschmidt a. Poltzer, B. 24, 1002). Plates (containing ² aq).—B'HCl. [254°].—B'₂H₂PtCl₂.

Di-phenyl-(αβ)-naphthotriazine C₂H₁₇N, i.e. C₁₀H₈ N.CHPh? [194°]. Got by heating a solution of CHPh:N.C₁₀H₄·N₂Ph in HOAc (Meldola, C. J. 57, 330). White flattened needles. PHENYL NAPHTHOPHENANTHRAZINE

 $C_{_0}H_{_1}CH_{_1}N > C_{_{10}}H_{_6}.$ The phenylo-nitrate B'PhNO3, formed by boiling phenanthraquinone with phenyl-naphahylene-diamine in HOAc and then adding HNO, crystallises in dichroice needles or prisms (Witt, B. 20, 1185).

(Py.3)-PHENYL-(a)-NAPHTHOQUINOLINE

C₁₉H₁₂N i.e. C₁₀H₄ CH:CH N=CPh. [68°], Formed by heating its (Py. 1)-carboxylic acid with sodalime (Döbner, A. 249, 114). Yellow needles (from alcohol-ether). Yields a syrupy tetra-hydride. Salts. -B'₂H₂PtCl₆2aq. -B'H₆Cr₂O₃.
B'C₆H₃N₃O₇. (167°). Thin needles (from alcohol). (Py. 3) Phenyl-(β)-naphthoquinbline. [188°].

(Py. 3)-Pannyi-(B)-napathoquinoine. [100]. Formed by heating its carboxylic acid with sodaline (D.). Needles or plates, insol. water, v. sol. alcohol.—B'_2H_PtCl_aq.—B'C_2H_N_0O. • [250°]. Yellow plates, sl. sol. ether.—B'_2H_Cr_0.

Pthyloiodide. [233°]. Plates, inscl.

(Py. 3)-PHENYL-(a)-NAPHTHOQUINOLINE (Py. 1)-CARBOXYLIC ACID C₂₀H₁₃NO₂ i.e. $C_{10}H_6 < N - CPh$ [300°]. heating (a)-naphthylamine with pyruvic acid and benzoic aldehyde in alcoholic solution (D.). Yellow needles (from alcohol-acetone). May be reduced to a tetrahydride. Produces, on oxidation, di-phenyl-pyridine tri-carboxylic acid and CO₂H.C₅NHPh< C₀H₄ NaA' ½nq. — ChA'₂4aq.

-ZnA'..-PbA'. -AgA': insoluble powder. Ethylether EtA': [103]. Needles.

(Py. 3)-Phenyl- (β) -naphthoquinoline (Py. 1)-(17). - 3)- Γ neny1-(15)- naphthoquinoline (17). 1)-carboxylic acid C₂₀H₁₃NO₂. • [296°]. • Formed in like manner from (β)-naphthylamino (D). Needles, v. sl. sol. alcohol. – ΚΑ΄ 5aq. – NaΑ΄ 5aq. – CaΛ΄, 6aq. – ZpΑ΄, 2aq. – Cu₂Λ΄, aq (?). – AgΑ΄. PHENYL-NAPHTHOQUINOXALINE

C₁₀H_u<N:CH N:CPh. The phenylo-bromide B'PhBr formed from phenyl-napl.thylene-diamine and bromo-acetophenone, crystallises in yellow plates, and is converted by NaOH into B'PhOH [148°], which crystallises in prisms, and yields B'PhNO₃ (Fischer a. Busch, B. 24, 1873). Di-phenyl-naphthoquinoxaline

C₁₀H₀N:CPh [147²]. Formed by heating naphthylene-(1,2)-diamine hydrochloride with benzil in alcohol (Lawson, B. 18, 2426). Lightbrown plates, v. sol. alcohol and ether.

Phenylo-hydroxide $C_{16}H_6 < N = CPh$ [167°]. Formed by oxidation of C₁₀H₄ N=CPh NPh.GHPh [164°], which is got by heating phenyl-naphthylene-o-diamine with benzoin at 200° (Fischer, B. 24, 722, 1871). Formed also from naphthylene-phenyl-diamine Formed by heating benzene-azo-(6)-naphthyl- and benzil (Fischer, B. 24, 2679). Yellow

prisms, insol. water, v. sol. ether.—B'HNO_s.—B'HCl: dark-yellow needles, v. sol. alcohol.

Di-phenyl-naphthoquinoxaline dihydride

C₁₀H₄ NPh.CH₂. [165°]. Formed, together with a compound melting at 195°, from naphthylene-phenyl-diamine and benzoyl-carbinol at 155° (Fischer a. Busch, B. 24, 2680). Orange needles, v. sol. benzene, v. sl. sol. alcohol.

PHENYL-NAPHTHOROSINDULINE

 $\begin{array}{c} C_{a}H_{\bullet} \diagdown \overbrace{C(NPh).CH:C.NPh.C:CH} \searrow C_{a}H_{\bullet} \quad [256^{\circ}]. \\ Formed, together with naphthyl-rosinduline, from \end{array}$ •benzene-azo-di-(a)-naphthylamine, hydrochloride, aniline, and alcohol at 165 '(Fischer a. Hepp, A. 256, 247). Deep-red bronzed plates. Conc. HClAq forms aniline and naphthorosindone [295°

DI - PHENYL - (a) - NAPHTHYL-ACETAMID-INE C. H. CK. C(NPh).NHPh. [130°]. Formed from (a)-naphthyl-acetic acid (3 mols.), aniline (6 mols.), and PCl, (Boessneck, B. 16, 642).

Needles, sol. ether and benzene.

PHENYLe(a)-NAPHTHYL-AMINE C. H 13N i.e. C. H . NH. C10 H7. [60°]. Forms by heating (a)naphthylamine hydrochloride with aniline at 250° (Girard a. Vogt, Bl. [2] 18, 67; Streiff, B. 13, 1852). Prepared by heating a mixture of (a)-naphthol (15 pts.), aniline (19.4 pts.) and CaCl, (11.6 pts.) under pressure for 9 hours at 280°; the yield being 26 p.c. of the theoretical (Friedländer, B. 16, 2077). White plates or prisms, v. sol. alcohol. Its solutions show blue fluorescence. Yields a tri-bromo- derivative [137°] and a di-nitro- derivative [77°]. H.SO, at 100° forms a tetra-sulphonic acid.—B'HCl: prisms, decomposed by water. - B'CaHaNaOa.

Acetyl derivative C. II, NO. [1150].

Benzoyl derivative. [152°]. Nitrosamine. Cult. NPh.NO. Nitrosamine. C., H., NPh.NO. [92°]. Reddish-yellow crystals (Eischer a. Hepp, B. 20, 1247).

Phenyl- (β) -naphthylamine $C_{10}H_{13}N$. [108] (395°). Formed by heating (B)-naphthol with aniline and ZnCl, at 190° (Merz a. Weith, B.13, 1300), or with aniline hydrochloride (Merz a. Weith, B. 13, 1850).

Preparation. - A mixture of (B)-naphthol (15 pts.), aniline (19.4 pts.), and CaCl₂ (11.6 pts.) is heated under pressure at 280° for 9 hours; the yield is 98 p.c. of the theoretical (Friedlander,

B. 16, 2075).

Properties.-White needles, sol. McOII. Yields a tetra-bromo- derivative [198] and a nitro- derivative [87°]. With nitroso-di-methylaniline hydrochloride and HOAc it yields lustrous black crystals, which form a violet solution in H_SO₄ (Witt, B. 21, 723). Sulphur at 240° forms

SC₀H-NH [178°] (Kym, B. 23, 2466).

H_SO₄ at 100° forms a trisulphonic acid

Salts .- B'HCl: unstable crystalline powder. -B'C, H, N, O, Brownish needles, v. sol. CHCl,

Acetyl derivative. [93]. Crystals. Benzoyl derivative. [136] (Streiff, A. 209, 151); [143] (Claus a. Richter, B. 17, 1591).

Nitrosamine C10H,.NPh.NO. [93°]. Di-phenyl-naphthylamine C10H, NPh2. [142°]. (335°-340° at 85 mm.). Formed by adding abromo-napht Halene (20 g.) to a boiling solution of potassium (8.8 g.) in diphenylamine (20 g.)

mixed with aniline (15 c.c.) (Herz, B. 23, 2541). Silky needles (from dilute alcohol), insol. water.

References .- NITRO-AMIDO-, DI-NITRO-, and NITROSO- PHENYL-NAPHTHYL-AMINE.

PHENYL-(a)-NAPHTHYLAMINE BLUE v. TRI - NAPHTHYL - TRI - AMIDO-TRI-PHENYL-CARBINYL CHLORIDE

PHENYL . (A) - NAPHTHYL - CARBAMIC ACID.

Ethylether C, H. NPh.CO, Et. Formed by the action of NaOEt on the chloride (Paschkowezky, B. 24, 2919). Satiny needles.

Phenyl ether Co.H.NPh.CO.Ph. [149° Fren'y tether C₁₀(1,Nrh.Oz.Ph. [149]). S. (96 p.c. alcohol) 36 at 17°, S. (benzene) 23 at 17°. Formed from the chloride and NaOPh. Needles, v. 81. sol. cola alcohol. Chloride C₂(H.NPh.COC), [102°]. Formed from phenyl (β)-naph@lamine and COCl₂ in

toluene (Kym, B. 23, 425). White plates.

PHENYL-(a)-NAPHTHYL CARBINOL

Ph.CH(OH).C, H, [86.5°]. (above 360°). Formed from the ketone, zinc-dust, and KOH (Elbs, J. pr. [2] 35, 504; cf. Lehine, B. 13, 359; Beckmann, B. 22, 915). Crystals, v. sol. alcohol. Gives a giolet colour with H2SO.

Phenyl-di-(a)-naphthyl carbinol C2, H200 i.c. Ph.C(C₁₀H,).OH. [160°-170°]. Formed, together with benzoic aldehyde, by boiling phenyl-(a)-naphthyl-(β)-pinacolin (C₁₀H₁).CPhBz (got by reducing phenyl (a)-naphthyl ketone with zine and alcoholic HCl) with alcoholic KOH (Elbs, J. pr. [2] 35, 507). Grey crystalline crusts (from ether-alcohol), m. sol. alcohol, v. sol. ether.

PHENYL - (8) - NAPHTHYL - CARBINYL - THIO-UREA. Tetrahydride C₁₀H₁₀N₂S i.e. NHPh.CS.NH.CH₂C₁₀H₁₁. [140°]. Formed from C₁₀H₁₁.CH₂NH₂ and phenyl thiocarbimide (Bamberger a. Helwig, B. 22, 1913). Vitreous rosettes.

PHENYL-NAPHTHYL-CARBINYL-UREA. NJIPh.CO.NH.CH,C, HI Tetrahydride Formed from naphthyl-carbinylamine and pheny cyanate (Bamberger, B. 22, 1913). The (a)-compound melts at 126.5°, the (β)-isomeride at 141°. Both crystallise in needles.

PHENYL-(a)-NAPHTHYLENE-DIAMINE $\mathbf{C}_{10}\mathbf{H}_{11}\mathbf{N}_{2}$ *i.e.* $\hat{\mathbf{C}}_{10}\mathbf{H}_{6}(\mathbf{NH}_{2})(\mathbf{NHPh})$ [1:4]. [148°] Formed by reducing nitroso-phenyl-(a)-naphthylamine (Wacker, A. 243, 305). Needles (from

alcohol) or plates (from benzene). Phenyl-o-naphthylene-diamine

C₁₀H₆(NH₂)(NHC₆H₅) [1:2]. Amido (β)-naph-thyl-phenyl-amine. [140°]. Formed, together with aniline, by reduction of benzene-azo-(β) naphthyl-phenyl-amine with SuCl, (Zincke a. Lawson, B. 20, 1170; Witt, B. 20, 1184). Broad needles or plates. Nitrous acid passed into HOAc (11 pts.) containing the hydrochloride in suspension forms $C_{10}H_1N_1O_2$ or $C_{10}H_{10}N_1O_2$ [208°], whence SnCl₂ forms $C_{10}H_{12}N_4$ [194°], which yields B'HCl, $C_{10}H_{11}AcN_4$ [261°] and $C_{10}H_{10}Ac_2N_4$ [177°], and gives with benzoic aldehyde a compound C23H16N4 [15.0°] (Zincke a. Campbell, A. 255, 349).

Salts .- B'HCl: long colourless glistening needles, v. sl. sol. water, more readily in alcohol. -XB'H.SO.: needles, similar solubility.

Phenyl-dinaphthylene-amine C26H1,N i.e. C₁₀H_eNPh. [c. 144°]. Formed by heating (ββ)-di-oxy-dinaphthyl with aniline-zinc-chloride. at 800° (Walder, B. 15, 2175). needles, sol. alcohol.—B'2C₄H₄N₄O₇. Prisms or [169°].

Di-phenyl-naphthylene-diamine [2:2] C₁₉H₄(NHPh)₂ [168°]. Formed, together with C₁₀H₄(OH)(NHPh) [163°], by heating dioxynaphthalene with aniline and CaCl₂ (Annaheim, B. 20, 1372; Clausius, B. 23, 528). Silvery plates (from hot benzene).

Acetyl derivative C26H22N2O3. [198°].

Di-phenyl-naphthylene-p-diamine [1:4] C₁₀H_a(NHPh)₂. [144°]. Formed by reducing the di-anilide of (a) naphth quinone with zinc, HOAc, and alcohol (Fischer a. Hepp, A.

256, 255). Colourless prisms.

DI - PHENYL - NAPHTHYLENE - DI-THIOUREA C₁₆H₄(NH•CS.NH•Ph)... 1355°-380°1. UREA C₁₀H₆(NHCS.NHPh)₂, [355°-350°]. Formed from naphthylene (1,2) diamine and phenyl-thio-carbimide (Damberger a. Schieffeline B. 22, 1376). Needles.

DI-PHENYL-NAPHTHYLENE-UREA

C₁₀H_a(NH.CO.NHPh)₂. [335°]. Formed from naphthylene (1,2)-diamine and phenyl cyanate (Bamberger a. Schieffelin, B. 22, 1376). Crystalline granules, v. sl. sol, benzene.

PHENYL-NAPHTHYL-ETHANE CasHin i.c. C, H, CH, CH, Ph. Formed by heating nai hthyl benzyl ketone with HI and P at 155° (Graebe a. Bungener, B. 12, 1078). Yields chrysene on passing through a red-hot tube.

s-PHENYĽ- (β) -NAPHTHYL-ETHYLENE C₆H₃.C₂H₂.C₁₀H₃. [145°]. Formed by distilling (β)-naphthyl cinnamate, CO₂ being split off (Anschütz, B. 18, 1946). Silvery plates. Di-bromide. [192°].

PHENYL-NAPHTHYL-ETHYLENE-4-THIO-

UREA NPh:C< $^{N(C_{10}H,)}_{S,CH_2}>$ CH $_{\bf r}$ [185°]. Formed from phenyl-(a)-naphthyl-urea and ethylene bromide (Foerster, B. 21, 1870)

DI-PHENYL-NAPHTHYL-GUANIDINE $C_{22}H_{10}N_3CN_3H_2Ph_2(C_{10}H_1)$. [155°]. Formed by heating di-phenyl-thio-urea with (a)-naphthylamine, alcohol, and PbO (Tiemann, B. 3, 6; Z. [2] 6, 309). Crystalline, sol. alcohol.

PHENYL - (B) - NAPHTHYL - GUANIDINE CARBOXYLIC ACID

C, H, NH.C(NH).NH.C, H4.CO2H. Formed by heating cyan-carbimidamido-benzoic acid with (β)naphthylamine (Griess, B. 16, 338). sl. sol. hot alcohol.-B'HCl. Six-sided plates.

PHENYL (α)-NAPHTHYL-KETONE
C₁₇H₁₂O i.e. C₆H₃.CO.C₁₈H₇. Mol. w. 232. [75·5°]. (385°) (Schweizer, A. 261, 196). V.D. 119 (calc.

5). S. (alcohol) 2.5 at 12°.

Formation. — 1. Together with the isomeride, by heating naphthalene with HOBz and P₂O₃ at 210° (Merz, B. 6, 541, 966, 1238).- By heating (a)-naphthoic acid with benzene and P₂O₅ (M.).—3. Together with a smaller quantity of the (β)- isomeride, by the action of AlCl, on a mixture of naphthalene, CS₂, and BzCl. The two ketones are separated by crystallisation from alcohol-ether (Elbs, J. pr. [2] 35, 503; B. 19, 1965; Rospendowski, C. R. 102, 872) .- 4. By heating naphthalene with BzCl and ZuCl., or Zn (Roux, A. Ch. [6] 12, 338; Kegel, A. 247, 178).

Properties.-Trimetric prisms, very slightly

volatile with steam, Reactions.—1. Br forms C₁₇H₁₁BrO [98°] (E.); [100.5°] (Rospendowski), whence HNO.

gives C17HaBr(NO2)2O decomposing at 90° .- 2. Conc. H.SO, with a few drops of water forms at 100°-150° benzoic acid and naphthalene (\$)sulphonic acid.—3. Soda-lime at 350° forms naphthalene and NaOBz.—4. Chromic acid mixture forms C,H,.CO.C,H,(CO,H),[1:2:3]. [155°] .-- 5. Sodium acting on its ethereal solution forms a greenish-yellow compound CPh(C₁₀H₁,)₂CO.C₂H₃ and other bodies, while CO₂ acting on the Na compound forms a yellow powder, split up by water into ketone and C₆H₃, C(C₁₀H₁)(OH, CO₂H [148°] (Beckmann a. Paul, A. 266, 10).

Oxim C_aH_aC(NOH).C_{1a}H_r. [142°]. Groups of white needles (from dilute alcohol) (Kegel, A. 247, 181). Oxidised by CrO_a in HOAc to $C_6H_5.CO.C_6H_3 < \frac{CO.CH}{CO.CH}$ [152°], which yields an anilide CoH3Bz CO.C.NHPh [200°] and a ptoluide [197°] both converted by boiling NaOHAq

into C,H,Bz < CO.C.OH [222°].

Phenyl (β)-naphthyl ketone [82°]. S. 2 at 12. Formed, at the same time as the (of- isomeride, from naphthalene (v. supra). Formed also by heating (β) -naphthoic acid with benzene and P₂O₅ (Merz). Needles, v. sol. hot alcohol.

Oxim. [176°]. Needles. Oxidised by CrO₃

in HOAc to yellow C,H,Bz CO,CH, which is converted by heating with aniline into dark-red plates of $C_sH_3Bz < \stackrel{CO.C.NHPh}{<} [210^\circ].$

Reference. -- DI - OXY - PHENYL - NAPHTHYL -KETONE

PHENYL NAPHTHYL KETONE o-CARB-OXYLIC ACID C10 H7.CO.C0H1.CO.H. [174°]. The chloride is formed from naphthalene, phthalic armydride, and AlCl, (Ador a. Crafts, Bl. [2] 31, 531). Prisms (from dilute alcohol). PHENYL - NAPHTHYL - METHANE v.

BENZYL-NAPHTHALENE.

Phonyl-di-(a)-naphthyl methane C2, H20 i.e. C_bH₃CH(C₁₀H₂)₂. [c. 180°]. Formed from phenyl-(a) naphthyl-(b)-pinacolin by distilling with zinc-dust. Got also by heating phenyl-di-(a)-naphthyl-carbinol with zinc-dust (Elbs, J. pr. [2] 35, 508). Grey powder; cakes together at 100

Di-phenyl-naphthyl-methane C10H7.CHPh4. [134° and 149°]. Formed by heating di-phenylcarbinol with naphthalene and P₂O₂ at 140° (Lehne, B. 13, 358; Hemilian, Bl. [2] 34, 326). Needles, sol. benzene and ether, sl. sol. alcohol.

PHENYL - (a) - NAPHTHYL - METHYL-PYR -ROLE CH:CPh NC₁₀H₇. [74°]. (above 360°). Formed by heating the carboxylic acid [244°] (Lederer a. Paal, B. 18, 2598). Plates. sol. alcohol, benzene, and ligroin.

Phenyl-(3)-naphthyl-methy.-pyrrole CH:CPh NC₁₀H_r. [52°]. Formed by heating the carboxylic acid [249°] (L. a. P.). white concentric needles. V. sol. alcohol

PRENYL - (a) - NAPHTHYL - METHYL - PYR-ROLE CARBOXYLIC ACID

CO.H.C-CMe NC, H,. [244°]. Formed by

heating acctophenoneacetoacetic ether with (a)naphthylamine at 130°, and saponification of the product (Lederer a. Paal, B. 18, 2598). Needles. sol. alcohol, benzene, and acetic acid.

Phenyl-8-naphthyl-methyl-pyrrole oxylic acid. [249°]. Formed in like manner. using (β) -naphthylamine (L. a. P.). Small white needles, sol. alcohol and HOAc.

Ethyl ether EtA'. [115°]. Plates. PHENYL - (8)-NAPHTHYL-METHYL-THIO-

UREA C10H,NH.CS.NPhMe. [127°]. Got from (B)-naphthyl-thiocarbimide and methyl-aniline •(Gebhardt, B. 17, 2091). Long yellow needles.

Phenyl-(a)-naphthyl-methyl-\psi-thio-urea C₁₀H,N:C(SMe),NHPh. [96]. Formed from phenyl (a)-naphthyl-thio-urea and MeI (Foerster, B. 21, 1870). Small white needles. Yield (a)-naphthyl-thiocarbinnide on Reating with CS. Yields

PHENYI⁴ (a) - NAPHTHYL (b) PINACOLIN C_aH₂,C(C₁₆H₃),CO.C_cH₃, [e, 130°]. From phenyl-(a) naphthyl ketone by boiling with zine and HCl (Elbs, J. pr. [2] 35, 505). Pale greenishyellow crystalline crusts, v. sol. ether, sl. sol. alcohol, insol. water. Cakes together at 100°-110°. Boiling alcoholic KOH forms benzoic aldehyde and phenyl-di-naphthyl-carbinol.

PHENYL - (a) - NAPHTHYL - PINACONE C₁₆H,CPh(OH).ĈPh(OH).C₁₆H, [61°]. A product of the action of sodium-amalgani on an alcoholic solution of phenyl-(a)-naphthyl ketone (Lehne, B. 13, 1360). Needles (from ether).
DI - PHENYL - (a) - NAPHTHYL - PYRROLE

CH:CPh CH:CPh>NC₁₀H₁. [149]. Formed by heating its carboxylic acid with lime (Paul a. Braikoff,

B. 22, 3092). Needles, v. sol. hot alcohol.

Di-phonyl-(B)-naphthyl-pyrrole. [208°].

Formed in like manner (P. a. B.). Needles.
DI - PHENYL - (a) - NAPHTHYL - PYRROLE CARBOXYLIC ACID CD.H.C CH:CPh NC10 H,

[272]. Got by saponifying its other, which is obtained from phenacyl-benzoyl-acetic other and (a)-naphthylamine (Paul a. Braikoff, B. 22, 3091). Small white plates, sl. sol. hot alcohol .-Sl. sol. hot water.

Ethyl ether EtA'. [182]. Needles. Di-phenyl-(β)-naphthyl-pyrrole carboxylic

acid. [above 350°]. Got in like manner, using
 (β) naphthylamine. Plates.—KA'. Sl. sol. water.
 Ethyl other Eth'. [182°]. Needles.

PHENYL-(a)-NAPHTHYL SULPHIDE

 $C_{16}H_7$.SPh. [42°] (K. a. B.); [49°]. (c. 215° at 15 mm.). Formed from Pb(SPh)₂ and $C_{10}H$ Br (Krafft a. Bourgeois, B. 23, 3047). Formed also from (a)-diazonaphthalene chloride and NaSPh (Ziegler, B. 23, 2471). Prisms (from dil. alcohol).

Phenyl (β)-naphthyl sulphide. [52°]. (c. 221° at 14 mm.). Formed in like manner. Needles. PHENYL (a) - NAPHTHYL SULPHONE SULPHONE C₂H₂SO₂·C₁H₂, [100°]. Formed by oxidising phenyl (a)-naphthyl sulphide with CrO₂ and HOAc (Krafit a. Bourgeois, B. 23, 3047). Formed also, together with the (B)- isomeride, by heating benzene sulphonic acid with naphthalene and P₂O₅ at 175° (Michael a. Adair, B. 10, 585). Crystals (from alcohol).

Phenyl (β) - naphthyl sulphone. Formed in five manner, and also by heating naphtfialens (β)-sulphonic acid with benzene and P₂O₂ (M. s. A.), and by the action of zinc-

dust or AlCl, on a mixture of naphthalene and benzene sulphonie chloride (Grustschoff, B. 7, 1167; Otto a. Beckurts, B. 11, 2069). Needles. PHENYL-(a)-NAPHTHYL-THIO-SEMICARB. AZIDE NHPh.CS.NH.NIIC, H,. [135°]. Formed

from (a)-naphthyl-hydrazine and phenyl-thiocarbimide (Preund, B. 24, 4191). Needles.

Phenyl - (B) - naphthyl - thio - semicarbazide. [202°]. Formed in like manner from (\$)-naphthyl-hydrazine (P.). White plates.

PHENYL •(a) - NAPHTHYL - THIO - UREA NHPh.CS.NHC₁₀H₇. [163²]. Formed from (A)-naphthylamine and phenyl-thiocarbinide (Hofmann, Pr. 9, 274), and also from aniline and (a)-naphthyl-thiocarbinide (Mainzer, B, 15, 1414). Plates, y. sl. sol. alcohol. With ethylene bromide it gives two bases [185°] and [130°].

Tetra hydride MIPh.CS.HIC.

[1537]. Formed from phenyl-thiocarbimide and (a) na phthylamine tetrahydride (Bamberger, B. 21, 1794). Prisms, v. sol. benzene-alcohol.

Phenyl-(B)-naphthyl-thio-urea

NHPh.CS.NHC₁₀H., [165°]. Formed from (β) -maplythylamine and phenyl thiocarbinide (M.; •Freund a. Wolf, B. 25, 1468). Plates. Split up by HClAq at 150° into anilino, (β) naphthylamine, and phonyl and (β)-naphthyl thiocarbinides. COCl, in toluenc forms NPh:C \(\sigma_{10}^{\text{NC}_{10}\text{H}_{1}} \) CO [117°].

Tetrahydride NHPh.CS.NHC, Hu. [161°]. Formed from phenyl thiocarbimide and (B). naphthylamine tetrahydride (Bamberger a. Müller, B. 21, 858). Prisms (from alcohol). PHENYL-(a)-NAPHTHYL-UREA. Tetra

hydride NHPh.CO.NHC, H₁₁. [193°]. Formed from (a)-naphthylamine tetrahydride and phenyl cyanate (Bamberger, B. 21, 1794). Needles.

u-Phenyl-(β)-naphthyl-urea

NH ... CO.NPh.C in H .. [190"]. Formed by heating NPh(G₁₀H₂).COOl and alcoholic NH, at 130° (Kym, B. 23, 426). Needles, sl. sol. cold alcohol.

Phenyl-(β)-naphthyl-urea

NHPh.CO.NHC, II, [221°]. Formed from phenyl cyanate and (B)-naphthylamine (Gold-

schnidt, B. 21, 2567). Prisms (from alcohol).

Tetrahydride NHPh.CO.NHC, H₁, [166].

Formed from phenyl cyanato and the tetrahydride of (B)-naphthylamine (Bamberger a. Müller, B. 21, 859). Needles, v. e. sol. alcohol.

Phenyl-di-(B)-naphthyl-urea C_nH_{2n}N₂O i.c. NHPh.CO.N(C_nH₁). [182]. Formed from phenyl cyanate and di-(B)-naphthylamine (Gebhardt, B. 17, 3039). Formed also by heating N(C₁₀H₁)₂.COCl with aniline in CHCl₃ at 130° (Kym, B. 23, 429; Kühn a. Landau, B. 23, 811). Needles (from alcohol). By heating with aniline it is converted into CO(NHPh)2 and di-(B)naphthylamine.

Phenyl-tri-(B)-naphthyl-urea

CO(NPhC₁₀H₁).N(C₁₀H₁)₂, [168°]. S. (alcohol) 9 at 16°; S. (be zene) 4'54 at 16°. Formed from (C₁₀H₁)₂N.COCl and phenyl-(3)-naphthylamine at 260° (Paschkowezky, B. 24, 2924). Granular crystals, sl. sol. cold alcohol.

Di.phenyl. (8). naphthyl. urea NHPh.CO.NPhC, H., [133°]. Formed from NPh(C, H,). COCl and aniline (Kym, B. 23, 426). White plates, sl. sol. cold alcohol.

u-Di-phonyl-di-(β)-naphthyl-urea NPh. CO.N(C, H,), [104°]. Formed by heat

ing NPh2.COCl with (C10H2)2NH at 220° or by heating (C₀H_.)₂N.COCl with NPh_.H at 260° (Paschkowezky, B. 24, 2923). Crystalline powder, m. sol. cold alcehol.

s-Di-phenyl-di-(β)-naphthyl-urea

CO(NPh.C₁₀H₇)₂. [186°]. S. (alcohol) 1 at 18⁵°. S. (benzene) 59 at 18⁵°. Formed by heating C10H,NPh.COCl with C1eH,NPh.COCl at 2500 (P.). Polyhedral granules. Converted by HClAq at 250° into aniline, (β)-naphthol, and CO₂.

Tri-phenyl-(β)-naphthyl-ures

NPh₂CO.NPh.(C₁₀H₇). [128°]. Formed from C₁₀H₇NPh.COCl and NPh₂H at 240° (P.). Crys-

talline powder, v. sol. alcohol.

PHENYL o-NITRO-BENZYL KETONE C.H., CO.CH., C.H., NO. Nilso-dcoxybenzoin. Formed, together with the p-isomeride by nitrating phenyl benzyl ketone (Ney, B. 21, 2448). Sol. ether (difference from p-isomeride), p-isomeride yields a crystalline &xim [107°].

PHENYL p-NITRO BENZYL OXIDE C.H.,O.CH.,O.eH.,NO. [91°]. Formed from p-nitro-benzyl chloride and KOPh (Kumpf, B. 17, 1076). Plates (from alcohol).

Reference. - NITRO - PHENYL - NITRO - BENZYL

OXIDE.

PHENYL NITRODIPHENYLETHYL KE. TONE C.H. CO.CHPh.CH2.C.H4NO2. Formed from nitro-benzyl chloride, deoxybenzoïn, and NaOEt (Buddeberg, B. 23, 2071). The o-compound melts at 102' and yields diphenylquinoline [96°] (420°) on reduction. The p- isomerice melts at 112° and yields an amido-compound [141°] on reduction.

DI-PHENYL-DINITROSACYL. So-called. C₁₆H₁₆N₂O₄. [87°]. The chief product of the action of HNO₃ (S. G. 1·4) on acctophenone (Hollemann, B. 21, 860, 2835). It is accompanied by an isomeride [179°]. Crystals (from ether). Converted by acids and alkalis into benzoic and oxalic acids, NH3, and hydroxylamine. Ac₂O yields C₁₆H₁₀Ac₂N₂O₅ Aniline and benzanilide form compounds melting at 205° and 160° respectively.

DI-PHENYL-NITROSAMINE v. Nitrosamine of DI-PHENYL-AMINE.

PHENYL-NITRO-TOLYL-THIO-UREA NITRO-PHENYL-TOLYL-THIO-UREA.

DI-PHENYL-NITRO-p-TOLYL-UREA

 NPh_2 .CO.NHC₆H₃Me(NO_2) [1:4:3]. [139.59] Formed from nitro-p-toluidine and NPh COCI at 125° (Lellmann a. Bonhöffer, B. 20, 2121). Yellow needles, v. sol. chloroform and benzene.

 $\begin{array}{ccc} \textbf{PHENYL-OCTINOIC} & \textbf{ACID} & \textbf{C}_{11}\textbf{H}_{10}\textbf{O}_2 & \textit{i.e.} \\ \textbf{PhC(C_2H_2)(C_2H_2Et).CO_2H} & (310^\circ – 320^\circ). & \textbf{This} \end{array}$ appears to be one of the products of the action of CO at 170° on a mixture of NaOEt and PhCH₂.CO₂Na (M. Schroeder, A. 221, 46).

PHENYL-OCTOIC ACID. Nitrile. C.H. CHPh.CN. (2879). Formed from phenylacetonitrile, hexyl iodide, and NaOH (Rossolymo, B. 22, 1237). Oil.

DI-PHENYL-n-OCTYL TRICYANIDE C.H., C.N.Ph. [43°]. (285° at 15 mm.). Formed from C.H., COCI, benzonitrile, and AlCl, (Krafft a. Koenig, B. 23, 2384).

PHENYL-OCTYL-THIO-UREA C15H21N2S i.e. C.H., NH.CS.NHPh. [53°]. Formed from aniline and sec-octyl-thiocarbimide (Jahn, B. 8, 804).

v-PHENYL-OSUTRIAZOLE C.H.N. CH:N NPh. [224°]. Formed by warming the osotetrazone of glyoxal with FeCl, and HClAq (Pechmann, A. 262, 291). Sl. sol. water, v. sol. alcohol. HNO, yields C(NO,):N NPh [184°].

Tri-phenyl-osotriazole CPh:N NPh. [122]. Formed by heating the diphenyl-dihydrazide of beazil with alcohol at 210 (Auwers a. V. Meyer. B. 21, 2806). Wlate plates.

PHENYL-OSOTRIAZOLE CARBOXYLIC' ACID CO₂H.C=N NPh. [192°]. Formed by oxidising phenyl-methyl-osotriazole with KMnO. (Von Pechmann, B. 21, 2760). Formed also by boiling the phenyl-hydrazide of di-ni roso-acetone with NaOHAq (Pechmann, A. 262, 283). White needles, sol. alcohols not volatile with steam. Yields a nitro-compound [236°] which may be reduced to an amido-compound [252°]

Methyl ether Had. [90]. (286°).

Ethyl ether Eth. [59°]. (306°).

Mide C.N., IPP. CONH... [143.5°]. Formed

by boiling the phenyl-hydrazide of acetyl-di-nitroso-acetone with Na₂CO₄Aq (P.). Needles.

Nitrile C.HN, Ph.CN. [94 5]. (191° at 60 mm.). Formed by the action of NaOH on the phenyl-hydrazide of di-nitroso-acetone (Pechmann, A. 262, 297). Plates, v. sol. ether. H2S and alcoholic NH3 convert it into the thio-amide C2HN3Ph.CS.NH2 [1323].

Phenyl-osotriazole dicarboxylic acid

C(CO.H):N NPh. [256°]. Formed by oxidising: phenyl-di-methyl-osotriazole with KMnO, (Pechmann, A. 262, 311). Crystalline powder. After fusion it melts at 184°.—CaA": needles.—Ag.A".

PHENYL-OSOTRIAZOLE CARBOXYLIC ALDEHYDE C(CHO):N NPh. [70°]. Formed by boiling its oxim with dilute H.SO. (Peclimann, A. 262, 294). Insol. cold water.

Oxim C2HPhN3.CH:NOH. [115°]. A product of the action of alkalis on the compound! CH(NOH).C(N2HPh).CH(NOAc).

Phenyl-hydrozide C.HPhN, CH:N, HPh. [118°-140°]. Plates, v. sol. alcohol.

PHENYL-OSOTRIAZYL ALCOHOL

CH₂(OH).C=N>NPh. [67°]. Formed, together with the carboxylic acid, by warming the aldehyde with conc. NaOHAq (Pechmann, A. 262, 296). Prisms, v. e. sol. alcohol, sl. sol. cold Aq.

PHENYL-OSOTRIAZYL-AMINE C.H., N. i.e. CH₂(NH₂).C=N CH:N>NPh. (233° at 100 mm.).

Formed from C₂HPhN₂.CS.NH₂, by treatment in alcoholic solution with Zn and HCl (Pechmann, A. 262, 300). — B'HCl. [229]. Tables. — B'₂H₂PtCl₃. Prisms. — Di-thio-carbamate. [123°]. Tables.

PHENYL-OXALACETIC ETHER C, H16O, i.e. CO2Et.CO.CHPh.CO2Et. Formed by the action of Na on a mixture of oxalic ether and phenylacetic ether (Wislicenus, B. 20, 591; A. 248, 339). Oil, decomposed by distillation, v. sol. alkalis, FeCl, colours its alcoholic solution red. Boiling

dilute H2SO, gives CO, and phenyl-pyruvic acid [155°].

Phenyl-hydrazide CO.Et.C(N.HPh).CHPh.CO.Et. [70°]. Needles

(from dilute alcohol), v. sol. ether.

Ethyl ether of the semi-nitrile
CN.CHPh.CO.CO.Et. [130]. Formed from phenylacetonitrile, oxalic ether, and Na or NaOEt (Erleneneyer, jun., B. 22, 1483). Plates. FeCl, colours its alcoholic solution green.

PHENYL-OXAMIC ACID t. OXALIC ACID. PHENYL-OXAMIDE v. OXALIC ACID. PHENYL-OXAMIDE CARBOXYLIC ACID v.

OXALIC ACID.

PHENYL-OXANTHRANOL C20II,4O2 C.H. (CPh(OH) C.H. [2080]. Formed by oxidation of phenyl-anthranol with K.Cr.O. and HOAc (Bacyer, A. 202, 58). Colourless tables, insol. water, sol. alcohol. Conc. H.SO, forms a purple solution. Reduced by zinc-dust and HOAc to phenyl-anthranol. Benzene and II SO, form crystalline CaH, O.

Acetyl derivative C. H13AcO. [1960]. Reference. —DI-CHLORO- and OXY-PHUNYL-

OXANTHRANOL.

PHENYL-OXAZOLE C.II, NO i.e.

CPh ≪ N :CH. [6°]. (221°). Formed by heating bromo-acetophenone with formamide at 140° (Lewy, B. 20, 2578; Blümlein, B. 17, 2580).— B'HCl. [80'].— $B'_2H_2PtCl_2$ 2aq; yellow needles. Di-phenyl-oxazole $CPh \in \stackrel{GH,O}{N}$:CPh. [103'].

(339°). Formed by heating a-bromo-aceto-phenone with benzamide at 145° (B.; L.). Plates (from alcohol). –B'HCl. Needles.

Phenyl-iso-cxazole CII Formed from the oxim of benzeyl-acetic aldehyde and AcCl (Claiserfa, Stock, B, 24, 134).

PHENYL-OXAZOLE DIHYDRIDE C, II, NO.

i.e. CH₂ CH₂O_N (213°). Formed by warming bromo-ethyl-benzamide with alkalis (Gabriel a. Heymann, B. 23, 2495). Liquid, smelling like phenyl-thiazole dihydride. Miscible with alcohol and ether, sl. sol. water. IBrAq forms bromocthyl - benzamide and CH₂(OB₂),CH_NH_{...}
B'₂H₂PtCl₆.—B'₂H₂Cr_.O₇.—B'C₄H₄N₄O₇. [177].

DI-PHENYL OXIDE C₁.H₁₀O i.e. Ph₂O. Mol.

w. 170. [28°]. (253°). μ_{A} —15675 at 25°.

Formation.—1. By distilling cupric benzoate (List a. Limpricht, A. 90, 190).—2. By warming diazobenzene sulphate or chloride with phenol (Hofmeister, B. 3, 747; A. 159, 201; Hirsch, B. 23, 3709). -3. By heating phenol with ZnCl. at 350°, the yield being 6 p.c. (Merz a. Weith, B. 14, 187).-4. By heating phonol with AlCl, (M. a. W.) .- 5. Together with diphenylene ketone oxide and a body melting at 111°, by distilling sodium salicplate with phenyl phosphate (R. Richter, J. pr. [2] 28, 273).

Preparation .- By distilling Al(OI'h), (Glad-

stone a. Tribe, C. J. 41, 6).

Properties. Prisms (from cold alcohol), smelling like geraniums, almost insol. water and KOHAq. Conc. H₂SO, forms O(C₄H₄SO₂H)₂, which forms Na₂A" xaq, BaA", and Ag,A".

References .- DI-AMIDO-, DI-BROMO-, and DI-MITEO- and DI-OXY- DIAMENYL OXIDE.

PHENYL-OXY-ACETAMIDINE v. MANDEL-AMIDINE.

PHENYL-OXY-ACETIC ACID v. Manuelio ACID.

DI-PHENYL-OXY-ANGELIC ACID v. Dihydro-conviculatio acid

nyaro-connectant acid.

PHENYL p-OXY-BENZYL KETONE

Call, CO.CH., C.H., OH. [129°]. Formed from CII, Bz.C., H., NH. by the diazo-reaction (Ney, B. 21, 2419). White spangles (from water).

Acityl derivative. [87°]. Plates.

Isomeride v. Benzoin.

PHENYL-OXY-BENZYL-UREA C, H, N,O, i.e.[12]C₄H₄(OH),CH₂NH+CO,NHPh. Formed by warming C₄H₄(OH),CH₂NH, with phenyl synate and benzene. Needles, sdl. alcohol and ether.

Methyl derivative

Methyl Cervolive
[1:2]C_H_(OMe).CH_MH.CO.NHPh. [145°].
Formed from C_H_(OMe).CH_NH, and phenyl
cyanate (Goldschmidt a. Ernst, B. 23, 2743).
PHENYLOXY-BROMO-PROPIONIC ACID v.

Bromo-oxy-phenyl-propionic acid

PHENYL OXYBUTYL KETONE C,1H,1O, i.e. C.H.CO.CH...CH...CH...CH...OH.. [41°]. Formed by boiling the anhydride of its carboxylic acid with water (Perkin, jun., C. J. 51, 733; 57, 310). Iridescent plates, v. sol. alcohol. If left to stand over H.SO, it is converted into the anhydride.

Oxim C, H, C(NOH), C, H, OH. [57]. Minute

plates, sl. sol. ligroin.

Anhydride C₁₁H₁₂O i.e. CH CH₂CH₂>O. | (250° at 720 mm.). Formed by heating its carboxylic acid at 200° (Perkin, B. 16, 1792; 19, 2559; C. J. 51, 730). Oil. Converted by HBrAq into phenyl bromo-butyl ketone.

PHENYL OXY-BUTYL KETONE CARB. OXYLIC ACID. Anhydride C12H12O2 i.e. CH₂ $\stackrel{\text{C(CO_2H):CPh}}{\underset{\text{CH}_2}{\text{CH}_2}} = 0$. Benzoyl-tetramethylene carbocylic acid. Phonyl dehydrohexone carbocylic acid. [1412]. Formed by saponification of its ether, which is made by the action of trimethylene bromide on sodium benzoyl-acetic when the (Perkin, jun., C. J. 51, 726; B. 19, 2557). Monoclinic crystals, $a:b:c=2\cdot638:1:3\cdot398$; $\beta=74\cdot44'$. V. sol. alcohol and other. Converted by conc. IIBrAq in the cold into C.H., CO.C.H., Br. - CaA", -PbA": white pp. -AgA': white pp.

Ethyl ether EtA'. [60°]. Monoclinio prisms; a:b:c = 1.002:1:.591; $\beta = 68^{\circ} 34'$.

Reference .- NITRO-PHENYL OXY-BUTYL KETONE ANHYDRIDE CARBOXYLIC ACID.

PHENYL - OXY - BUTYRIC ACID v. Oxy-PHENYL-BUTYRIC ACID.

PHENYL OXY- \psi - CUMYL KETONE

C, H, CO.C, HMe, OH. [187°]. Formed by the action of nitrous acid on phenyl amido-\(\psi\)-cumyl ketone (Fröhlich, B. 17, 1806). Plates, v. sol. alcohol, sol. alkalis.

PHENYL OXYETHYL SULPHONE

C6H5.SO2.C2H4OH. Formed by heating glycolic chlorhydrin with sodium-benzene sulphinate and a little water at 120° (Otto, & pr. [2] 30, 186). Prepared by boiling C.H. (SO, C.H.) with KOHAq. Liquid, sl. sol. water, miscible with alcohol and ether. Reactions. - 1. Conc. H2SO, forms C_uH₅.SO₂.C₂H₄.O.SO₃H, which yields 3½BaA', aq, crystallising from water in needles .- 2. Sodiumamalgam reduces it to alcohol and Ph.SO.H or PhSH.-3. PCl, forms PhSO_C.H.Cl, crystallising from benzene in six-sided tablets [56°].-4. I'Cl, forms the sparingly soluble anhydride (Ph.SO, O,H), O [70°].—5. Aqueous NH, at 120° forms (Ph.SO, C,H,) NH.—6. Chromic acid

oxidises it to Ph.SO.CH.CO.H Acetyl derivative Co.H.SO. Oil. Benzoyl derivative Ph.SO.C.H.OBz

[125° PHENYL OXY . METHYL KETONE v.

BENZOVL-CARBINOL.

PHENYL - OXY - NAPHTHYL Ethyl derivative C₁₀H_a(DE).CO.C₁H₃. [75]. Formed from C₁₀H₁.OEt, BzCl, and AlCl₂ (Gattermann, B. 23, 1209). Needles.

Phenyl-di-oxy-naphthyl ketons $C_6H_5.CO.C_6H_3 < \stackrel{C(OH).CH}{C(OH).CH}$ [191°]. Formed by boiling (a)-benzoyl-naphtnoquinone with SnCl, and alcohol (Kegel, A. 247, 183). White plates.

Acetyl derivative. [155]. Plates. Isomeride v. DI-OXY-PHENY NAPHTHYL-KE-

PHENYL-OXYPHENYLBIAZYL-HYDRAZ. INE NPh.N C.NII.NHPh. [181°]. Formed by heating di-phenyl-carbazide with COCl, at 100° (Freund a. Kuh, B. 23, 2831). White crystals, insol. benzene. Oxidised by FeCl, to C,N,PhO,N:NPh [200°].

PHENYL - OXY - PHENYLTHIOBIAZYL -HYDRAZINE NPh.N C.NH.NHPh.

Formed by the action of COCl. on di-phenyl, thiocarbazide, the resulting C2N2PhSO.N:NPh [140°] being reduced by alcoholic ammonium sulphide (Freund a. Kuh, B. 23, 2827). Needles.

DI-PHENYL-DIOXYPHENYLENE KETONE v. DIOXYPHENYLENE DIPHENYL DI-

PHENYL-OXY-PIVALIC ACID v. p-oxy-PHENYL-VALERIC ACID.

PHENYL-OXY-PROPIONIC ACID v. Oxy-

PHENYL-PROPIONIC ACID.

DI-PHENYL OXYPROPYLENE DISUL-PHONE CH(OH)(CH., SO., C, H)... Formed by oxidation of the product of the action of NaSPh on dichlorhydrin (Otto a. Rössing, B. 23, 758).

Oil, v. sol. alcohol.

Benzoyl' derivative. [150]. Needles.

DI-PHENYL OXY-PROPYL SULPHONE. Anhydride (C,H,SO,CH,CH,CH,CH,)O. [85° Formed by heating di-phenyl trimethylene disulphone with alcoholic potash at 120° (Otto, B. 24, 1833). Hexagonal tables, insol. water.

PHENYL OXYTOLYL KETONE. Methyl derivative. C. II., CO.C., II., Me.OMc. [80°].
Formed from C., H., Me(OMc), BzCl, and AlCl., (Koenigs a. Carl, B. 24, 3897). Crystals.
PHENYL-OXY-VALERIC ACID v. OXY-

PHENYL-VALERIC ACID. Di-phenyl-oxy-valeric acid v. Tetrahydro-

CORNICULARIC ACID. PHENYL-PARABAMIC ACID v. PARABAMIC

PHENYL-PARACONIC ACID v. Anhydride of Oxy-BENZYL-SUCCINIC ACID and NITRO-PHENYL-PARACONIC ACID.

DI-PHENYL-PENTADECYL TRICYANIDE C₃N₃Ph₂(CH₂)₁₁CH₂. [64°]. (328° at 13 mm.). Formed by heating benzonitrile with palmityl chloride and AlCl, from 40° to 100° (Krafft a.

Hansen, B. 22, 809). Globular groups of needles (from isobutyl alcohol), v. sol. ether. PHENYL PENTADECYL KETONE

PHENYL FERMAN C₃H, CO.C₁, H₃₁. [59°]. (251° at 15 mm.). Formed from palmityl chloride, benzene, and AlCl₂ (Krafit, B. 19, 2982; 21, 2266). Plates " = lookell sol. ether. Yields benzoic and pentadecoic acids on oxidation.

Reference.—Oxy-phenyl pentadecyl ketone. PHENYL-PENTANE v. AMYL-BENZENE.

PHENYL-PENTANE DICARBOXYLIC ACID CO,H.C,H,CEt,CO,H. [198°]. Formed by the action of KOHAq upon its anhydride

CuHi CO O [53°], which is got by the action of alcoholic potash and EtI on di-oxyethyl-isoquinoline (Pulvermacher, B. 20, 2494).
Crystalline.—Ba\(\frac{1}{2}\)'.—Ag_A''; yellow powder.
Phenyl-pentane tricarboxylic \(\frac{1}{2}\)her

Thenyl-pentane tricarboxylic gher CHEt(CDL).C(CH_Ph)(CO_Et), (336° cor.), S.G. 40 1.0899. \(\text{\$\mu_n\$}\) 1.0897 at 20°. Formed from sodium butane tricarboxylic ether and benzyl chloride (Bischoff a. Mintz, B. 23, 654). Yields, on saponification, two benzyl-ethyl-succinic acids [157.5°] and [123.5°]

Phenyl-pentane tricarboxylic acid CMe₂(CO₂H), C(CH.Ph)(CO₂H)₂, [178°]. Ethyl ether Et₃A''', (337° cor.), S.G. $\frac{29}{100}$ 1 0950. $\mu_{\rm B} = 1.4831$ at 20°, Formed in like manner from isobutane tricarboxylic ether (B. a. M.). Yields, on saponification, the acid and also benzyl-di-methyl-succinic acid [155°].

Phenyl-peutane tri-carboxylic acid CHMe(CO2H).CH2.C(CH2Ph)(CO2H)2. One of the acids got by saponifying the product of the action of benzyl chloride on sodium isobutane tricarboxylic ether (Bischoff, B. 23, 1947). Plates (from water).

Di-phenyl-pentane tetra-carboxylic ether CH_(C(CO_Et)_CH_Ph),. (c. 240° at 20 mm.). Formed from disodium propane tetra-carboxylic ether and benzyl chloride (Dressel, A. 256, 191). Thick oil.

PHENYL-PENTENOIC ACID C, H, O2 i.c. H. Hydrocinnamenylacrylic Formed by reduction of phenyl-C₆H₅,C₄H₆,CO₂H₆ acid. [31°]. pentinoic acid by sodium-amalgam (Bacyer a. Jackson, B. 13, 122). Plates. Yields di-oxy-phenyl-valeric acid on oxidation by alkaline KMnO, (Fittig a. Mayer, A. 268, 51).

Dibromide. [109°]. Prisms. PHENYL-PENTINOIC ACID C11H10O2 i.e. C.H., CH:CH.CH:CH.CO.H. Styryl-acrylic acid. [166]. Formed from cinnamic aldehyde, Ac.O. and NaOAc (Perkin, C. J. 31, 403; Fittig, 268, 50). Prisms (from water). On oxidation by alkaline KMnO, it yields benzoic aldehyde and racemic and oxalic acids (Doebner, B. 23, 2374).—SrA'₂ 2aq. —Ag,A''.

Chloride C₁₂H₁₂OCl. [25°].

Amide. [186°]. Tables (from alcohol).

Di-phenyl-pentinoic acid

C.H.CH:CH:CPh.CN. [119°]. Formed from cinnamic aldehyde, phenyl-acetoritrile, and NaOEt (Freund a. Immerwahr, B. 23, 2856). Needles, v. sol. alcohol and ether.

Reference .- NIIRO- and OXY-PHENYL PEN-TINOIC ACID.

PHENYL-PHENTRIAZINE. Dihudride. $C_{\bullet}H_{\bullet} <_{CH,NPh}^{N=N}$ [128°], Formed by adding NaNO₂ to a solution of o-amido-benzyl-phenyl-hydrazine or o-amido-benzyl-aniline in HClAq at 0° (Busch, B. 25, 448). Plates, v. sol. alsohol. Salts.—B'HCl.—B'2H₂PtCl₆. [130°].—B'O₂H₁N₁O₂. [111°]. Orange-red needles. PHENYL-PHENTRIZZOLE C₁₂H₁N₁ i.s.

PHENYL-PHENTRIAZOLE C₁₂H_uN_s i.e. C_eH_i≪N_N NPh. [109°]. Occurs as a bypeoduct in the manufacture of amido-azo-benzene (Gattermann, B. 21, 1633). Formed by the action of phenyl-hydrazine on brono-di-nitro-benzene, the resulting nitro-phenyl-phentriazole [1:4:5]C_eH_z(NO_e):N_zPh being fiduced to amido-phenyl-phentriazole (183°) and NH_z then elimnated (Kehrmann a. Messinger, B. 25, 899).

Isomeride C.H. $\stackrel{\text{NPh}}{\sim}$ N. Phenyl-phenyl-ene-azimide. [90°]. Formed from o-amido-diphenylamine and nitrous acid (Schöpff, B. 23, 1843). Needles, sol. alcohol.

PHENYL-PHEN-(β)-NAPHTHACRIDINE

C_sH₄ $\stackrel{N}{\subset}_{CPh} \searrow C_{10}H_s$. [198° uncor.]. Formed by heating a mixture of phenyl-(β)-naphthylamine and benzoic acid with P₁O_s or ZnCl. (Chaus a. Richter, B. 17, 1595). Sublimes in white needles.—B'.H.2PCL: glittering vellow needles.

DI-PHENYL PHENYL ACETYLENE DI-KETONE v. Dehydro-acetofhenone-benzil, vol. i. p. 37.

Di-phenyl-diphenylacetylene diketone v. Oxylepiden, vol. iii. p. 137.

PHENYL-PHENYL-AMIDO-ACETIC ACID C₃H₁Ph.NII.CH_CO_11. Formed from p-amido-dipnenyl and chloro-accide acid (Zimmermann, B. 13, 1966). Plates (from hot water).—EtA'. [95°]. Needles (from dilute alcohol).

FHENYL PHENYL-AMIDO-ETHYL KE-TONE C,H,,CO.C,H,NHPh. [38*]. Formed from C,H,,COC.H,Br and amiline (Pampel a. Schmidt, B.19, 2896). Yellow crystals.

Acetyl derivative. [103°]. Needles.

PHENYL PHENYL-AMYL RETONE
C18H NO i.e. C. H. CO. CHPh. CH. Pr. [78?]. (330°
cor.). Formed from phenyl benyl ketone,
NaOEt, and isobutyl brounde (V. Meyer a.
Oelkers, B. 21, 1295). Needles. Yields an oxim

[118°] crystallising in prisms. • PHENYL-PHENYL-BENZAMIDINE

C₂₀H₁₆O i.e. C₃H₁Ph.CO.CH.Ph. [150²]: (above 360²). Formed from diphenyl, phenyl-acetic chloride, and AlCl₃ (Päpeke, B. 21, 1339). Plates (from alcohol). Converted by NaOEt and CSCl₂ into C₃H.Ph.CO.CPh.CS [above 220²].

PHENYL PHENYL-BUTYL KETONE

C. H. CO.CHPhBr. [33°]. (330°). Formed from sodium deoxybenzon and n-propyl bromide (Bischoff, B. 22, 346). Thread-like needles (from alcohol). Yields an oxim [100°].

Phenyl phenyl isobutyl ketone

C.H., CO.CHPhPr. [48°]. (325°). Yields an

oxim [70°] and a phenyl-hydrazide [72°].

DI.PHENYL-DI.PHENYL-OARBINOL

(C.H.Dh.,CH.OH. [151°]. S. (alcohol) 1.25; ether) 9; (ligroin) 5 at 65°. Got by reducing

the corresponding ketone with sodium-amalgam (Adam, A. Ch. [6] 15, 260; cf. Weiler, B. 7, 1189). Plates.

PHENYL-DI-PHENYL-CARBINYLAMINE
C_aH_b, C_aH_b, CHPh.NH_c... \$77°]. Got by reducing
the oxim C_aH_b, C_bH_b, C(NOH), C_aH_b by sodium
amalgam (Koller, M. 12, 518). Needles (from
ether), insol. water. Conc. ILSO, forms a deepviolet colour, becoming claret-red on warming.

-B'HQAc.[161°]. White needles (from water).

-B'HCl... [252°]. White needles.—B'HNO₃,
[211°].—B'₂HPCl_a'4aq. [191°]. Yellow needles.

-Phenyl-triphenylcarbinyl-amine

NHPh.CPh₂, [146°]. Formed from aniline and CPh Br (Elles, B. 17, 703; Hemilian a. Silberstein, B. 17, 746). Hevagonal prisms, v. sol. (Sz., Yields a enitrosamine [c. 156°] and a fetra sulphonic acid C₂, H₁₁(SO, H). N which yields easily soluble Ba₂A* and Cu₂A*.

PHENYL TRI-PHENYL-CARBINYL KE-TONE v. (β). ΒΕΝΣΡΙΝΑΡΟΙΙΝ.

• DI-PHENYL-DIPHENYLENE - DI-UREA. NHPh.CO.NH.C.H.,C.H.,NH.CO.NHPh. [above 300°]. Concentric needles (from aniline). Formed by adding phenyl cyanate (2 mols.) to an othereal solution of benzidine (Kühn, B. 18, 1478).

PHENYL PHENYL-ENNYL KETONE
C₆H₃,CO.CHPh.C₇H₁, [61°], (350°–355°),
Formed from deoxybenzoin (E. Bischoff, B. 22,
348). Yields an oxim [101°] crystallising in
long needles.

PHENYLPHENYL ETHYL ALCOHOL [1:3]C,H,Ph.CHMe.OH. [86]. Formed by reducing G,H,Ph.CO.CH, with sodium-amalgam (Adam, A. Ch. [6] 15, 257). Crystalline mass. Cannot be distilled.

DI-PHENYL DIPHENYLETHYLENE DI-KETONE CHIPhib. CHPhib.. Bidesyl. Hydrocarlepiden. [255°]. Formed as described in vol. ii, p. 139. Needles (from benzene), insol alcohol. On boiling for two hours with alcohol it changes to an isomeride [261°], sol. alcohol (Fehrlin, B. 22, 553).

Isomeride. [161]. Isobidesyl. Accompanies bidesyl when prepared from deoxybenzoïn, NaOEt, and I, or from BzCHBrPh_NaOEt, and deoxybenzeïn (Knövenagel, B.21, 1356). Prisms (from alcohol). Reacts with hydroxylamine forming C₂₀H₂N₂O₄ [110²-120"]. Cone. H₂SO₄ forms with bidesyl and isobidesyl a green solution, turning brown. NH₂ forms tetraphenyl-pytrole.

PHENYL PHENYL-ETHYL RETONE C.H., CO.CHMe.C.,H., [53?]. (318° cor.). Formel from C.H., CO.CHNa.C.,H., and MeI (V. Meyer a. Oelkers, B. 21, 1297). Needles (from alcohol). Forms an oxim [120°].

Phenyl phenyl-ethyl ketone C₅H₅,CO.CH.-CH₂-C₅H₃. [73°]. (above 360°). Formed by reducing phenyl styryl ketone with zinc-dust and HOAc (Schneidewind, B. 21, 1325). Plates (from alcohol). Yisids an oxin [87°]. Isoamyl nitrite and NaOEt form C₁₅H₁₅NO₂ [126°].

Phenyl diphenyl-ethyl ketone C.H.,CO.CHPh.CH.Ph. [120°]. Formed from phenyl benzyl ketone, NaOEt, and benzyl chloride (V. Meyer a. Oelkers, B. 21, 1300). Needles (from alcohol). Yields an oxim [208°].

PHENYL PHENYL-ETHYL KETONE CARBOXYLIC ACID C.H., CO.CHPh.CH., CO.H. [152°] (J. a. M.); [161°] (M. a. O.). Formed by oxidising dehydro-acetone-benzil with CrO, and HOAc (Japp a. Miller, B. 18, 184). Needles .--

BaA', 2aq.—AgA'. Ethyl ether Formed from Ph.CO.CHNaPh and ClCH2CO2Et (V. Meyer a. Oelkers, B. 21, 1305). When heated it yields an anhydride OCO CH₂ [152°], whence ammonia forms NH CO .CH₂ [189°]. Phenylhydrazine acting on desylacetic acid forms C₂M₁₈N₂O [110°] and (C₂M₁,N₂O)₂[243°]. The former, NHPh.N CO .CH₂? may be reduced by Na and isoamyl alcohol to NH CO—CH₂
CHPh.CHPh

[207°] Aniline converts the acid into NPh CO .CH. [190°] and

NPh CO .CH .CH .CO NPh not melted at 800°.

Phenyl phenyl-ethyl ketone carboxylic acid. Methyl other CoH_CO.CH(CO_Me).CH_Ph. C₆H₂CO.CH(ČO₂Me).CH₂Ph. (c. 253° at 50 mm.). Formed from methyl benzoyl-acetate, NaOEt, and benzyl chloride (Perkin a. Calman, C. J. 49, 155).

Phenyl di-phenyl-ethyl-ketone carboxylic acid C_{2.}H₁₆O₃ i.e. C₆H₃CO.CH_{2.}CPh_{2.}CO₄H₅ [183°]. Formed by heating the lactone of oxytri-phenyl-crotonic acid with alcoholic potash (Japp a. Klingemann, C. J. 57, 681). Plates. Reduced by boiling HIAq to tri-phenyl butyrolactone. Phenyl-hydrazine in alcoholic solution yields $C_{22}H_{21}N_{21}O$, which is reduced by Na and isoamyl alcohol to oxy-tri-phenyl-pyriole dihydride $C_{22}H_{18}NO$.—NH₄A'.—AgA'. On heating with alcohol and hydroxylamine hydrochloride it forms C₂₂H₁₇NO₂ [152°] and C₂₁H₁₇NO [143°].

Methylamide C₂₂H₁₇NO₂. [156°]. Formed

from tri-phenyl-crotolactone and methylamine.

Ethylamide. [130°]. Needles.

Phenyl tri-phenyl-ethyl ketone carboxylic

acid. Mathylamide CeH. CO.CHPh. CPh. CONHMe. [260°]. Formed by heating the lactone of oxy-tetra-phenyl-crotonic acid with alcoholic NH, Me at 100° to 200° (Klingemann a. Laycock, B. 24, 514). Plates, sl. sol. alcohol. Yields, on distillation,

NMe CO .CPh. [158°].

PHENYL PHENYL-HEPTYL KETONE C₆H₃.CO.CHPh.C₆H₃. [59°]. (345°). Needles or plates (from alcohol). Yields an oxim [89°] (Bischoff, B. 22, 347).

PHENYL-DI-PHENYL-HYDRAZINE

NHPh.NHC, H,Ph. [127°]. Formed by reducing C.H.N.C.H.Ph with ammonium sulphide (Locher, B. 21, 911). Needles or plates (from dilute alcohol). Yields a di-acetyl derivative [203°]

PHENYL-DI-PHENYL KETONE v. PHENYL-BENZOPHENONE.

PHENYL-PHENYL MERCAPTAN C12H108 i.e. C.H.Ph.SH. [111°]. Formed by educing C.H.Ph.SO.cl with tin and HCl (Gabriel a. Deutsch, B. 13, 386).—Pb(S.C.H.Ph), Reddish

brown pp.—C₁₂H₉SMe. [108°]. Needles (Obermayer, B. 20, 2927).

DI-PHENYL-DI-PHENYL-METHANE

(C₈H₄Ph)₂CH₂. [161°]. (360°). Formed from diphenyl, methylal, HOAc, and H₂SO₄ (Weiler, B. 7, 1188). Forned also from diphenyl, CH₂Cl₂, and AlCl₃; the yield being bad (Adam,

A. Ch. [6] 15, 254).
DI - PHENYL DI - PHENYL - METHYLENE DISULPHIDE CPh₂(SPh)₂. [139°]. Formed by passing dry HCl into a hot mixture of benzophenone, phenyl mercaptan, and ZnCl₂ (Baumann, B. 18, 889). Prisms (from ether).

PHENYL-PHENYL DI PHENYL ETHYL KETONE C, II, Ph.CO.CHPh.CH, Ph. [158°]. Formed from C.H.Ph.CO.CH.Ph, NaOEt, and

benzyl chloride (Papeke, B. 21, 1339). Needles (from alcohol). Yields an oxim [175°]. PHENYL PHENYL PROPINYL KETONE CARBOXYLIC ACID CPhiC.CHBz.CO.2II. [135°]. (c. 275° at 40 mm.) Formed from di-benzoylpropionic ether and alcoholic potash (Kapf a. Paal, B. 21, 1488). Yellow needles or plates, insol. water. Phenyl-hydrazine forms C.,IL,N,O [100°]. Boiling with alcohol and HClAq forms di-phenyl-furfurane carboxylic acid [217°]. Alcoholic NH, yields di-phenyl-pyrrole carboxylic

ether.—KA'2aq: yellow needles (from alcohol).
PHENYL a. PHENYL-PROPYL KETONE C₆H₅.CO.CHEtPh. [58°]. (324° cor.). Formed from phenyl benzyl ketone, NaOEt, and EtI (V. Meyer a. Oelkers, B. 21, 1299). Needles.

Yields an oxim [130°]. Phenyl phenyl-propyl ketone

C_bH₃CO.CH₂.CHPh.CH₃ or C_bH₃.CO.CMc₂Ph [70°]. (340°-345° i.V.). Formed by heating acetophenone with HI and P at 140° (Graebe, B. Plates (from alcohol), v. e. sol. other.
 PHENYL DI-PHENYL-PROPYL THIO-UREA NHPh.CS.NII.CH, CHFh.CH, 14. [129°]. Formed from di-phenyl-propyl-amine and phenyl

thiocarbimide (Freund a. Remse, B. 23, 2862). PHENYL PHENYL - PYRAZYL KETONE C₃H₂PhN₂CO.C₆H₃. [123°]. Formed by heating phenyl-pyrazole with BzCl at 245° (Balbiano, G. 19, 139). Needles (from dilute alcohol). Yields an oxim [154°] and a phenyl-hydrazide [140°].

DI-PHENYL-DI-PHENYL SULPHIDE

CaH, S i.e. (CaH, Ph) 28. [172°]. Formed by distilling Pb(S, CaH, Ph), (Gabriel a. Deutsch, B. 13, 386). Plates, sol. alcohol and ether.

Di-phenyl di-phenyl disulphide (C,H,Ph).S. [150°]. Formed by atmospheric oxidation of C_aH₄Ph.SH (G. a. D.). Needles, sol. alcohol and CS...

PHENYL-PHENYL SULPHOCYANIDE C_eH₄Ph.SCN. [84°]. Formed from Pb(SC_eH₄Ph)₂ and ICy (Gabriel a. Deutsch, B. 13, 389). White

crystals.

DI-PHENYL-DI-PHENYL SULPHONE

(C_aH₄Ph)₂SO₂. [216°]. Made by oxidising (C_aH₄Ph)₂S with KMnO₄ (Gabriel a. Deutsch, B. 13, 387). Plates, sl. sol. ether.

.PHENYL-PHENYL-SULPHONO-BENZAM-IDINE PhC(NPhH):NSO₂Ph. [139]. Formed by the action of aniline on the imido-chloride obtained from the anilide of benzene sulphonic acid by the action of PCl, (Wallach a. Gossmann, A. 214, 214). Narrow plates (from alcohol). Appears not to combine with HCl. On dry dis80, and phenyl sulphides.

PHENYL PHENYL THIOCARBIMIDE C.H.Ph.N:CS. [58°]. Formed by distilling (C.H.Ph.NH) CS with P.O. (Zimmermann, B.

13, 1964). Needles.
PHENYL PHENYL-THIO-GLYCOLLIC ACID C.H.Ph.S.CH..CO.H. [170°]. Formed from chloro-acctic acid and C.H.Ph.SNa (Gabriel a. Deutsch, B. 13, 389). Colourless crystals, sl. sol water.

Phenyl-phenyl-di-thio-di-glycollic acid C₁₂H₈(S.CH₂.CO₂H)₂. [252⁻]. Formed from C₁₂H₃S₂Pb and ClCH₂.CO₂H. Crystals.

DI PHENYL-DI PHENYL-THIO UREA $CS(NH.C_6H_4Ph)_2$ [228°]. Formed from p-amidodiphenyl and CS, (Zimmermann, B. 13, 1963). Plates.

PHENTL PHENYL DI-TOLYL CARBINYL

RETONE v. Phenyl-tolyl-pinacolin.
PHENYL-PHENYL-p. TOLYL-CARBINYLUREA NHPh.CO.NH.CHPh.C.H.Me. [206]. Formed from C₆II₁Me,CHPh.NH₂ and phenyl cyanate (Goldschmidt a. Stöker, B. 24, 2802).

PHENYL PHENYL-DI-XYLYL-CARBINYL KETONE v. PHENYL-XYLYL-PINACOLIN.

PHENYL PHOSPHATES.

Mono - phenyl di - hydrogen phosphate C.H.O.PO(OH)2. Phenyl-phosphoric acid. [982]. A product of the action of P.O. on phenol (Rembold, Z. 1866, 652; Jacobsen, B. 8, 1519; Rapp, A, 224, 157). Deliquescent needles. Partially decomposed by boiling water into phenol and phospheric acid. Yields phenol and HPO, on distillation. -CaA". -BaA": prisms.

Chloride C, H, O.POCl₂ (242°). A product of the action of POCl₃ on phenol. Formed also from Cail, O.PCl, and SO, (Anschütz a.

Emery, A. 253, 110).

Di-phenyl hydrogen phosphate (C₀H₂O)₂PO.OH. [56°] (R.). A product of the action of P₂O₂ on phenol. Formed also by boiling (PhO)₂PO (1 mol.) with aducous KOH (1 mol.) (Glutz = 143 *30°) and by January (1 mol.) (Glutz, d. 143, 193), and by decomposing the chloride with water. – BaA'₂, – AgA'. – NII₃PhA'. [c. 160°] (Wallach, B. 8, 1235).

Chloride (C.H.O).POCI. (315° at 272 mm.). Formed from phenol and POCI. Oil, slowly de-

composed by water.

Anilide (CaH5O)2PO.NHPh. [129]. Sixsided tables, v. sl. sol. water (W.).

Tri-phenyl phosphate $(C_0H_3O)_3PO$. [45°] (J.). (245° at 11 mm.) (A. a. E.) Formed, together with chlore-benzene, by the action of PCl, on phenol (Williamson a. Scrugham, C. J. 7, 240). Formed also from phenol and POCl, (Jacobsen), or PCl, (Glutz), followed by water. It is also a product of the action of water on C_oH₂O.PCl, (Auschütz a. Emery, A. 253, 110).

Preparation .- A mixture of phenol (280 pts.) and phosphorus oxychloride (150 pts.) is heated to boiling with an inverted condenser for 16 hours, the excess of phenol is removed by distillation or by shaking with dilute NaOH; the yield is 90 p.c. of the theoretical (Heim, B. 16, 1763).

Properties .- Needles, insol. water, sl. sol. alco-

hol, v. sol, ether.

Reactions. — By distillation with sodium acetate or benzoate it gives phenylacetate or benzoate. Heated with potassium sulphide it

tillation it gives di-phenylamine, benzonitrile, | yields tri-phenyl-thio-phosphate PS(OCaHa), together with phenol and some diphenyl and di-phenyl oxide. On distilling with MgO, PbO, ZnO, or CaO the chief product is phenyl, together with some diphenylere-oxide (Kreysler, B. 18, 1716). Chlorine passed into its cold ethereal solution forms (C₆H₅O)₃PCl₂ (A. a. E.).

Reference.—NTRO-PHENYL-PHOSPHATES.

PHENYL-PHOSPHINE C₈H₃PH₂. Mol. w. 110. (161°). S.G. 15 1.001. A product of the action of algohol on C₆H₅PI₃H and on C₆H₅PGl₂ (Michaelis, B. 7, 6; 10, 807; 12, 338; A. 181, 303). Pungent liquid.

Reactions. -- 1. Absorbs oxygen, forming CH₃PHCOH [70°]. --2. Sulphur at 100° forms liquid C.H.PH.S and solid (C.H.P), S [1380] .- 3.

CS, at 150° forms C II, P.S, Salts.—C, H, PH, I. Needles.—B', II, PtCl, Phenyl-di-chloro-phosphine C.H.PCl Phosphenyl chloride. Mol. w. 179. (225° cor.). S.G. § 13428 (Thorpe, C. J. 37, 347). Formed by passing benzene and PCl, through a red-hot tube. Formed also by heating HgPh2 with PCl2 at 180°, and by the action of AlCl, on a mixture of befizene and PCl₄ (Michaelis, B. 12, 1009; A. 181, 280). Pungent fuming liquid, decomposed by water into HCl and CaH PHO.OH [70°]. Chlorine forms CaH, PCl, [73°], which is split up at 180° into CaH, Cl and PCl, and is converted by water into C₆H₃PO(nH). SbCl₅ forms C₆H₄PCl₅SbCl₅, an unstable yellow crystalline powder. Br yields C₆H₄PCl₆H₇ (208°] and C₆H₄PCl₈Br₄. HI forms C₆H₄P'HI₅. H₈S yields oily (C₆H₆PS)₂ and crystalline C₂H₄m₈S₅ [198°]. S forms liquid C₆H₄PSCl₂ (270°) (Kë'iler, B. 13,

Phonyl-di-bromo-phosphine CallaPBr2. [257°]. Got from HgPh, and PBr, (Michaelis, B. 9, 519). Liquid. Br yields C, H, PBr, [207°] and

C.H.PBr.

Di-phenyl-phosphine (C,H,)2PH. (c. 280°). S.C. 10 1.07. Formed, together with the acid (C.H.) PO.OH by the action of dilute NaOHAq on (C.H.) PCl (Michaelis a. Gleichmann, B. 15, 801; Dörken, B. 21, 1508). Oil, v. sol. alcohol. Weak base. Yields (C.H.)2PO.OH on oxidation. CS, forms $(C_nH_n)_n^2H_nCS_n$ [167°]. — B'HCl. Crystalline. — B'_4H_P'LCl_6. — B'HL.

Di-phenyl-chloro-phosphine $(C_nH_n)_n^2PCl$.

(320°). S.G. 12 1 229. Formed from HgPh, and C₆H₃PCl₂ at 225° (Michaelis, B. 10, 627; 18, 2109; A. 207, 208). Formed also by heating C.H.P.Cl. in a scaled tube for 120 hours at 300° (Dörken, B. 21, 1505). Thick liquid, decomposed by water or Na.CO.Aq into (C.H.).PH and (C,H,),PO.OH. Absorbs oxygen from the air forming (C,H,)2POCl.

Tri-phenyl-phosphine P(C₆H₅)₄. [79°]. (abovo 360°) (Michaelis, B. 15, 802, 1610; A. 229, 297). Formed from C₈H₅PCl₂, bromobenzene and Na. Prepared by adding sodium to a mixture of Pol. (1 mol.) and C.H.Br (3 mols.) diluted with 4 volumes of dry ether and kept cool. The reaction is completed by boiling for 12 hours, and the ether is filtered off and evaporated to crystallisation.

Properties.—Large prisms or tables, sol. alcohol, ether, and benzene, insol. water.

weak base. Does not combine with CS₂.
Salts.—B'HI. [215°]. Prisms, sol. alcohol,
insol. water.—B'₂H₂PtCl₂.—B'HgCl₂.

by water.

Alkyto-halides .- B'Mel. [183°] .-B'MeClaq. [213°]. Crystals, v. e. sol. water and alcohol, insol. ether.—B'_Me_PtCl_. [238°]. B'Etl. [165°]. — B'PrI. [201°5°]. — B'PrI 261°1. [165°]. — B'PrI. B',C,H,Sr. [aloove our].

Benzylo-nitrate B'C,H,NO. [203°]. S.

838 at 15°. Needles (from water).

Benzylo-picrate B'C,H,C,H,N,O., [448°].

Benzylo-bichromate (B'C,H,),Cr.O., Benzylo-sulphocyanide B'C,H,SCN.

[189°]. Prisms, v. sol. alcohol, sl. sol. water. Tri-phenyl-phosphine oxide (C,H,),R). [153.5°]. (c. 360°). Formed by oxidising triphenyl-phosphine with Brand NaOHAq or with conc. HClAq and KClO₂. Prisms (containing aq), sl. sol. water, v. e. sol. alcohol. Yields two trinitro-compounds [68°] and [242°], the latter of which yields a tri-amido-compound [258°], whence bromine water forms OP(C6H2Br2(NH2)), [206°]. -B'HNO. [75°]. Yellow needles, decomposed

Tri-phenyl-phosphine sulphide (C.P.,), PS. [157.5°]. Formed from Ph,P and S in CS,. Colourless needles, v. sol. alcohol, insol. water.

Tri-pkenyl-phosphine selenide (C_dH₅)₃PSe. [184°]. Formed from Ph₃P and Sc. Needles.

Tetra-phenyl-diphosphine P₂(C₃H₂), (67°), (400°). Formed from (C₃H₂)₂PCl and (C₃H₃)₂PH (Dörken, B. 21, 1509). With GS₂ at 138° it forms Ph₂PCS.8PH₂Ph₃ [157°], insol. ether. **PHENYL-PHOSPHINIC ACID** v. PHENYL-

PHOSPHITES.

Di-phenyl-phosphinic acid (C,H,)2PO.OH. [190°] (Michaelis, B. 8, 922; 11, 885; 15, 802; 18, 2113). Formed by oxidation of (CaHa) PCI or of di-phenyl-phosphine. Needles, sl. sol. cold

alcohol.—CaA', 3aq.—AgA': bulky pp.

Ethyl ether Eth'. [165°]. Need

Phenyl ether (CaH,),PO.OCaH,. Needles Phenyl ether (CaH.) PO.OCaH. [186°]. Formed by oxidising (CaH.) POCaH. (265°-270°), which is got by warming (CoHa), PCl with phenol.

Small needles, sol. hot alcohol, insol. water. PHENYL PHOSPHITES.

Mono-phenyl dihydrogen phosphite C.H.O.P(OH) Formed by adding water to C₆H₅O.PCl₂ (216°) which is got by the action of PCl₃ on phenol (Noack, A. 218, 90; Anschütz, A. 239, 310). Uncrystallisable syrup, decomposed by addition of more water into phenol and HaPOs

Isomeride C_cH,PO(OH)... Phenyl phosphinic acid. Phosphenylic acid. Benzene phosphunic acid. [158]. S. 23·5 at 15°. Formed by the action of water on C_oH,PCl, (Michaelis, A. 181, 321). Plates, sol. alcohol and ether. Yields, on

321). Plates, sol. alcohol and ether. Yields, on nitration, $C_bH_a(NO_2)PO(OH)_r$ [132°], which may be reduced to crystalline $C_bH_a(N\Pi_2).PO(OH)_r$.— NaHA"zaq. — Na,A" 12aq. — CaH,A", — CaA"2aq.—SrH,A.", 2aq.—CuA".—Fe,A", 23aq. Ethers.—Me,A.", (247°).—Et,A", (257°).
—EtHA".—Et&gA".—PhHA". [57°]. Formed from $C_bH_aPOCl_r$ by successive treatment with phenol and boiling water. Needles, sl. sol. water.—Ph.A". [63·5°]. Formed from phenol and C.H. POll.

and C.H.POl.

Chloride C₆H₂POCl₂. (258°). Formed from C₄H₄PCl₄ and water, and also from C₄H₄PCl₅ and O. Thick liquid.

Di-phenyl hydrogen phosphite (C,H,O).POH. Formed by adding a little water to the compound (C₈H₅O)₂PCl (295° at 731 mm.) which is got from phenol and PCl, (N.). Uncrystallisable. Decomposed by more water into H.PO. and phenol.

Tri-phenyl phosphite (C_aH₃O)_aP. (220° at 11 mm.). S.G. 73 1184. Formed by heating phenol (3 mols.) with PCl₃ (1 mol.) at 230° in a current of dry CO, (Noack, A. 218, 91; Anschütz a. Emery, A. 239, 311). Neutral liquid, v. sol. alcohol. Decomposed by water into phenol and $\Pi_a PO_3$. Dry bromine forms $(C_aH_aO)_aPBr_a$, which is converted by water into $(C_aH_aO)_aPO$.

PHENYL-PHTHALIDE v. Anhydride of Oxy-BENZYL-BENZOIC ACID.

Di-phenyl-phthalide i.e. $C_0H_4 < \frac{CPh_2}{CO} > 0$.

Phthalophenone. Tri-phenyl-carbinol carboxylic anhydride. [115°]. Formed by the action of AlCl, on a mixture of benzene and phthalyl chloride (Friedel a. Crafts, A. Ch. [6] 1, 523, Baeyer, B. 12, 612; A. 202, 50) or of benzene with [1:2]C, H, Bz.CO.OAc (Von Pechmann, B. 14, 1866). Got also by heating phthalyl chloride with HgPh, (Noelting, B. 17, 387). Plates (from alcohol). Insol. KOHAq, sol. boiling alcoholic potash, but reppd. by acids.

Reference. - DI-AMIDO-DI-PHENYL-PHTHALIDE.
DI-PHENYL-PHTHALIDE CARBOXYLIC ACID v. Anhydride of Tri-Phenyl-Carbinol Di-CARBOXYLIC ACID.

PHENYL-PHTHALIMIDE v. Phenyl-imide of PHTHALIC ACID.

PHENYL-PHTHALIMIDINE C, H, NO i.e. $\mathbf{c}_{_{6}}\mathbf{H}_{_{1}} < \stackrel{\mathrm{CH}_{2}}{\sim} \mathbf{NPh}$. [160°]. Got by heating phthalide with aniline at 210° (Hessert, B. 10, 1450; 11, 239; Racine, A. 239, 88). Formed also by reducing the phenylimide of phihalic acid with tin and HClAq (Graebe, A. 217, 305). Plates (from alcohol), v. 81. sol. hot water.

PHENYL-PIPERAZINE v. PHENYL-PYRAZINE HEXAHYDRIDE.

PHENYL-PIPERIDINE v. PHENYL-PYRIDINE HEXAHYDRIDE.

PHENYL-PROPANE v. CUMENE.

Di-phenyl-propane CH_((CH_Ph)₂. Di-benzyl-methane. (290°-300°). Formed by heating di-benzyl ketone with HlAq and P at 180° (Graebo B. 7, 1623). Got also from CH_Cl.CHCl.CH_Cl, benzene, and AlCl, (Claus, B. 18, 2935). Liquid.

Di-phenyl-propane CH₂Ph.CHPh.CH₃, (291°-295°). S.G. ² 996. Formed from benzene, AlCl₃, and propylene chloride or allyl chloride (Silva, C. R. 89, 606). Formed also by adding H.SO, to a cooled mixture of toluene and styrene (Kraemer, Spilker, a. Ebenhardt, B. 23,

3274). Oil, sol. alcohol and ether.
Di-phenyl-propane CMe₂Ph CMe,Ph, Formed by the action of benzene and AlCl, on CCl_Me₂ or CH₂:CCl.CH, (Silva, B. [2] 34, 674; 85, 289).

Tri-phenyl-propane C₂H₃(C₆H₃), (340°). Formed by the action of AlCl, upon a mixture of benzene and glyceryl tri-promide or tri-chloride (Claus a. Mercklin, B. 18, 2935). Oil.

PHENYL - PROPANE TRICARBOXYLIC ACID CH,Ph.C(CO,H),CH,CO,H. [168:5°]. Formed from benzyl-malonic ether, NaOEt, and chloro-acetic ether (Fittig, A. 256, 92).

Small prisms, m. sol. warm water. Vields benzyl-succinic acid [161°] when boiled with water.—Ca, Λ'', c b, aq.—Ba, Δ'', 2 l, aq.—Ag, Λ''.

Ethyl ether Et, Δ'''. (336° cor.). S.G.
19 1-1079. μ_D=1-481 at 20°. Formed from

sodium ethane tricarbexylic ether and benzyl chloride (Bischoff a. Mintz, B, 23, 653).

Di-phenyl-propane tetra-carboxylic acid. Di-nitrile of the di-ethyl ether (CO_Et)_C(CH_,C_6H_,CN)_. [86°]. Formed from sodium malonic ether and [1:2]C,H,(CN).CH,Cl (Hausmann, B. 22, 2019). Prisms.

Tri-phenyl-propane dRarboxylic Imids C₆H₄<C(C,H,) CO. [174°]. Formed from C,H, CH, CO,NH, benzyl chloride, and

NaOEt (Pulvermacher, B. 20, 210%). plates (from alcohol).

Benzyl-imide CanHanNO...

PHENYL PROPARGUL OXIDE Callato i.e. CaHa.O.CaHa. (210). S.G. 4 1.216. Formed AgA': plates (from hot water). by the action of alcoholic potash on the bromoallyl derivative of phenol (Henry, C. R. 96,

1233). Liquid.
PHENYL-PROPARGYL-UREA C, H, N, O i.e. CH:C.CH, NH.CO.NHPh. [133]. Formed from propargylamine oxalate, phonyl cyanate, and K.CO,Aq (Paal a. Hempel, B. 24, 3042). Needles.

PHENYL-PROPENYL-AMIDINE C.H. N. [58°]. Formed from propionitrile, HCl, and anilino (Michael a. Wing, 4m. 7, 72). Hexa-

gonal plates, sol. alcohol and ether. —B'.H.PtCl.,
PHENYL PROPENYL METHYL KETONE CARBOXYLIC ACID C. Higo, i.e.

CH, CO.C(CH, CO.H): CHPh. [125°]. S. 3 at 100°; 5 at 15°. Formed by boiling benzoic aldehyde with acetyl-propionic acid and NaOAc (Erdmann, A. 254, 187).—BaA', 5aq. - CdA', 2aq.

Methyl ether Med. (c. 215° at 35 mm.).

PHENYL PROPENYL SULPHIDE C.H. S.CMe:CH. (208°). Formed by heating phenyl-sulphydro-crotonic acid (Autenrieth, A. 254, 232). Yellowish oil, volatile with steam.

TRI-PHENYL PROPENYL TRISULPHONE C.H.(SO,Ph),. [226°]. Got from CHBr(CH,Br), and sodium benzene sulphinate (Stuffer, B. 23,

3). Needles, m. sol. hot alcohol. DI-PHENYL-PROPENYL-DI-UREA

CEt < N .CO.NHPh .CO.NHPh[170°]. Formed from propionamidine and phenyl cyanate (Pinner, B. 23, 2924). Needles, m. sol. alcohol. Yields diphenyl-urea [234°] when boiled for a long time with alcohol. Boiling dilute HOAc forms NHPh.CO.NH.CO.C.H., [137°].

PHENYL-PROPIOLIC ACID C, H.O. i.e.

C.H., C.C.CO.H. Mol. w. 146. [137].

Formation. -1. By the action of Na and CO. on ω -bromo-styrene (Glaser, Z. [2] 4, 328; A. 154, 140). -2. By choiling a 3-di-bromo-phenyl-propionic acid or its ether with alcoholic potash (G.; Perkin, un., C. J. 45, 173; Weger, A. 221, 70; Roser, A. 247, 138).—3. By boiling a bromocinnamic acid with alcoholic potash (G.; Bairisch, J. pr. [2] 20, 181).

Properties.—Trimetric twin crystals. Re-

duced by zinc and HOAc to cinnamic acid (Aronatein a. Hollemann, B. 22, 1181) and by sodium-amalgam to phonyl-propionic acid. Dry HCl passed through its solution in HOAc forms two chloro-cinnamic acids [142°] and [132°] (Michael, J. pr. [2] 40, 63).

Salts .- KA' .- BaA' aq: square tables .-BaA', 2aq: needles. - BaA', 3aq. - CuA', 4aq. -

AgA': sparingly soluble pp. Ethyl ether EtA'. (260°-270°).

References .-- AMIDO- and NITRO- PHENYL-PROPIOLIC ACID.

a-PHENYL-PROPIONIC ACID C,H10O2 i.e. CH₂,CHPh.CO.H. Hydratropic acid. (268°). Formed by reducing atropic acid (15 g.) with (5 p.c.) sodium-amalgam (90 g.) (Trinius, A. 227, 262; cf. Kraut, A. 148, 244; Fittig, A. 195, 165). Got also from acetophenone by treatment with HCy, the resulting CH₂-CPh(OH).CN being saponified and the oxy-phenyl-propionic acid reduced by HI and P (Janssen, A 250, 135).
Oil, with characteristic odour. Yields atrolaction acid GH_J.CPh(OH).CO₂H on oxidation by alkaline KMnO₄.—BaA'..2aq.—CaA'..3aq. — CaA'..2aq. —

Methyl ether MeA'. (221°). Ethyl ether Eth'. (230°) $(230^{\circ}).$

 $1.0147 * R_{\infty} = 83.3 \text{ (Brühl)}.$

[92°]. Plates. Formed by Amide CHMePh.CONH₂. [92° Nitrile CHMePh.CN. (232°). the action of PCl, on the amide, and from sodium phenyl-acetonitrile and McI (Oliveri, G. 18, 572).

B-Phenyl-propionic acid CII Ph.CH2.CO II. Hydrocinnamic acid. Mol. w. 150. [48.7]. (280° i.V.). H.C.v. 1,084,600. H.C.p. 1,085,500. 41.F. 105,500 (Stohmann, J. pr. [2] 40, 135). S. 6 at 20°. A product of the putrefaction of albumen, 20 g. being got from 5 kilos 61 ox-brain (Stöckly, J. pr. [2] 24, 17).

Formation.-1. By reduction of cinnamic acid by sodium-amalgam or III (Erlenmeyer, A. 121, 375; 137, 327; Popoff, Bl. [2] 4, 875; Giacosa, II. 8, 108).—2. By reducing αβ-dibromo-phenyl-propionic acid (Schmitt, A. 127, 319). 3. From ethyl-benzene vid CH_Ph.CH_Cl and CH.Ph.CH...CN (Fittig, Z. 1869, 166; A. 156, 249).- 4. By oxidising phenyl-propyl alcohol (W. von Miller, B. 9, 274).-5. By heating benzyl-malonic acid (Conrad, A. 204, 176).

Properties .- Needles (from water), sol. alcohol and other; volatile with seam. When taken internally it is secreted as hippuric acid

(E. a. H. Salkowski, B. 12, 663).

Salts. - NII₄A'. Plates, v. e. sol. water.—
CaA'₂ 1½aq.—CaA'₂2aq.—BaA'₂2aq.—PbA'₂aq.
ZnA'₄—AgA'. Phenyl-hydrazine salt: ZnA'₂.—AgA'. Phenyl-hydrazine salt [57°]; silky needles (Liebermann, B. 24, 1107).

[57°]; silky needles (Liebermann, 2. . . . , Methyl ether McA. (239° cor.). S.G. 2 1.0155. S.V. 196.0. Liquid, with peculiar odour. Ethyl ether Eth. (218° cor.). S.G. 2 S.V. 221.5 (Lossen, A. 254, 63).

n. Propyl ether PrA'. (262° oor.). S.G. 2 1.0152 (Weger, A. 221, 79). S.V. 246.

Isoamyl ether C.H., A'. (202°). S.G. 2

·981; 49 ·952 (E.,.

Benzyl ether C,H,A'. (c. 300°). S.G. 21 1 074. Formed by warming benzyl acetate with sodium (Conrad a. Hodgkinson, B. 10, 254; A. 193. 300).

Amide C.H., NO. [105°]. Formed by heating the ammonium salt at 230° (Hofmann, B. 18, 2740). Small needles.

Nitrile C.H.N. (261° cor.). S.G. 1 1.0014.

Occurs in the oil of Nasturtium officinale (Hofmann, B. 7, 520).

Di-a-phenyl-propionic acid CH, CPh, CO, H. [173°]. (above 300°). Made by oxidation of the (6)-pinacolin of acetophenone CPh.Me.CO.CH, [41°] with chromic acid mixture (Thörner a. Zincke, B. 11, 1993). Formed also by dissolving pyruvic acid and benzene in H,SO, at 0° (Böttinger, B. 14, 1595). White leaflets, sol. ether, alcohol, and hot water.—KA'—CaA'₂1½q—BaA' 2aq.—AgA': white pp.

αβ-Di-phenyl-propionic acid CH_Ph.CHPh.CO_H. [84°]. Formed by the action of sodium-amalgam on a mixture of benzylehloride and ClCO₂Et (Wurtz_BC. R. 70, 350). Got also by feducing phenyl-cinnanic acid (Oglialoro, J. 1878, 821). Needles, sl. soliling water.—CaA'₂.—PbA'₂. [146'].—AgA'. Nitrile CH₂Ph.CHPh.CN. [58°]. (c. 335°)

(Janssen, A. 250, 133).

Di-S-phenyl-propionic acid CHPh₂CH₂CO₂H. [145°]. Formed from allocinnamic acid, benzene, and H₂SO₄ (Liebermann a. Hartmann, B. 25, 960). Needles. - CaA'...

aaß-Tri-phenyl-propionic acid CH,Ph.CPh,CO₂H. [162°]. Formed by saponifying the nitrile with HOAc and fuming HClAq at 220° (Neure, A. 250, 147). White needles, v. sl. sol. water .- AgA': white insoluble powder.

8l. 80l. water.—Aga: white insolution powder.

Nitrile CH.Ph.CPh..CN. [1262]. Formed
from CHPh.CN, benzyl chloride, and NaOEL.

Tri.s-phenyl propionic acid Ph.C.CH..CO.H.

[177°]. Formed from Ph3C.CH(CO.Et)2 by boiling with alcoholic potash (Henderson, C. J. 51, 226; B. 20, 1014). Prisms (from alcohol), v. sl. sol. water.—KA'aq.—NaA'aq.—BaA'₂aq. -AgA'. Minute needles.

Ethyl ether EtA'. [81°].

References .- AMIDO-, AMIDO-SULPHO-, BROMO-, BROMO-SULPHO-, BROMO-AMIDO-, BROMO-NITO-, CHLORO-, IODO-, IODO-OXY-, NITRO-AMIDO-, NTRO-OXY-, NITRO-, OXY-AMIDO- and OXY- PHENYL-PROPIONIC ACID.

PHENYL-PROPIONIC ALDEHYDE

C.H. CH. CH. CHO. [208°]. Formed from and water (Etard, A. Ch. [5] 22, 254). Oil. Forms a crystalline compound with NaHSO₃.

Oxim. Oil. Yields a solid hydrochloride. Ac.O rapidly forms phenyl-propionitrile; hence it is a syn- oxim (Dollfus, B. 25, 1918).

PHENYL-PROPYL ALCOHOL C₉H₁₂O i.e.

CHPhEt.OH. Mol. w. 136. (216°). S.G. 1.016. Formed by reducing phenyl ethyl ketone with sodium-amalgam (Errera, G. 16, 322; cf. Barry, B. 6, 1007. Got also from benzoic aldehyde by successive treatment with ZnEt, and water (Wagner, Bl. [2] 42, 330). Yields CHPhEt.OAc (228° i.V.) and oily CHPhEtCl.

Phenyl-propyl alcohol CH_Ph.CH_CH_OH, (235° uncor.) (213° at 360 mm.). S.G. $^{\frac{30}{4}}$ 1 0079. $\mu_{\mathcal{B}}$ 1 5478. $R_{\infty} = 68.79^{\circ}$ (Brühl, A. 200, 191). Occurs in storax as phenyl-propyl cinnamate (Miller, A. 168, 202). Prepared by reducing cinnamyl alcohol with sodium-amalgam (Rüg-Heimer, B. 6, 214; A. 172, 123; Hatton a, Hodgkinson, C. J. 39, 319; Errera, G. 16, 310). Viscid oil. Heating with conc. HClAq yields CH_Ph_CH_CH_CI (219°), whence NaOEt forms CH.Ph.CH. CH.OEt (220°).

Acetyl derivative C.H.Ph.OAc. (245°).

Phenyl-isopropyl alcohol CH, Ph.CH(OH).CH3. Methyl-bensyl-carbinol. (215°). Got by reducing benzyl methyl ketone

(E.). Liquid, with pleasant odour.

Di-phenyl-propyl alcohol CH₂Ph.CHPh.CH₂OH. (301°). Formed by warming di-phenyl-propylamine nitrito (Freund a. Remse, B. 23, 2863). Oil, sol. alcohol.

PHENYL-PROPYL-AMINE $C_{\mu}H_{13}N$ CH_LPh.CH_,CH_,NH_, (222° i.V.). Formed by reducing the phenyl-hydrazide (20 g.) of cinnamic aldehyde dissolved in alcohol (300 g.) by (2) p.c.) sodium-amalgam (700 g.) and HOAc (700 g.) and hOAc (700 g.) and hOAc (700 g.) (70 g.) at about 30°, the yield being 30 p.c. of the theoretical (Tafel, B. 19, 1930; 22, 1857). Liquid, m. sol. water, miscible with alcohol and ether. Absorbs CO2 from air, forming a crystalline mass. The squeous solution is strongly alkaline B'HCl. [218°]. Plates B'H, SO. B'₂H₂C₂O₄. [156°]. Needles. — B'H₂C₂O₄.— B'₂H₂PtCl₆. Plates, sol. hot water.

Phenyl-isopropyl-amine CH2Ph.CHMe.NII2. (203°). Formed by the action of Br and KOHAq on the amide of phenyl-isobutyric acid (Edeleano, B. 20, 618). Liquid.—B',H,PtCl, Needles.

Isomeride v. CUMIDINE.

Di-phenyl-propyl-amine

CH_Ph.CHPh.CH_NH₂. (316°). Formed by reducing the nitrile (30 g.) of phenyl-cinnamic acid dissolved in alcohol by treatment with Na (75 g.) (Freund a. Remse, B. 23, 2860). Liquid, sol. alcohol. Forms with HgCl₂ a crystalline compound [107°].—B'HCl. [190°]. Needles.— Aurochloride [145°].

Di-acetyl derivative. [85°]. Needles.

PHENYL - n - PROPYL - TRIAZOLE CARB. OXYLIC ACID N.NPh C.CO2H.

Formed by sayonifying the nitrile which is made from phenyl-hydrazine dicyanide and butyric anhydride (Bladin, B. 425, 179). Cubes (from alcohol) or prisms (from benzene). -CuA', laq.-

AgA'. Bulky white pp.

A mide C₂N₃PhPr.CO.NH₂. [1225°]. The thio-amide C₂N₃PhPr.CS.NH₄ [130·5°] is got by the action of alcoholic ammonium sulphide on the nitrile.

Phenyl-isopropyl-triazole carboxylic acid N.NPh C.CO.H. [155°]. Formed in like manner (B.). Prisms. - HA'HCl. Needles. -

Thanher (D.). Trishis.—IA 170.

CuA', 2]aq.—AgA: minute tables.

Methyl ether McA'. [76°].

Amide. [128°]. Needles. The thio-amide

C.N.Ph.Pr.CS.NH. [148°], formed by the action

of alcoholic NH, and H, S on the crude nitrile,

crystallises in yellow needles. DI - PHENYL - DI-ISOPROPYL-TETRAZONE NPhPr.N:N.NPhPr. [79°]. Formed by oxidising phenyl-isopropyl-hydrazine with HgO (Michaelis a. Philips, A. 252, 281). Octahedra.

DI-PHENYL-PROPYL TRICYANIDE

CPh N:CPh N. [78.5°]. (239° at 15 mm.). Formed from benzonitrile, butyryl chloride, and AlCl, at 75° (Krafft a. Von Hansen, B. 22, 807). Decomposed by dilute H2SO, into NH2, butyric acid, and HOBz.—B',H,PtCl. Needles.

PHENYL-PROPYLENE v. ALLYL-BENZENE.

PHENYL PROPYLENE • ψ · THIO · UREA $_{\sim 10}^{10} H_{11}N_{12}S$ i.e. CHMe.S C.NHPh. [117°]. Formed from the isomeric phenyl-allyl-thio-urea [95°] and HClAq at 100° (Prager, B. 22, 2992). Oxidised by potassium chlorate and HClAq to $_{\sim}^{10} H_{\rm C} \times S_{\rm CM}$

CHMe.SO₃ C.NHPh [192°]. — B'_.H,l'tCl₈. — CH₁. — N B'C₈H,N₃O₅. [154°]. Yellow needles. D1 - PHENYL - ISOPROPYL - GLYOXALINE

TETRA - HYDBIDE GHPr NPh.QH2 [95°], Eormed from di-phenyl-ethylene-diannine and isobutyric aldehyde (Moos, B. 20, 734). Crystalline groups (from alcohol), sl. sol. water.

PHENYL-PROPYL-HYDRAZINE C, II, IN. i.e. C, II, NH. NHPr. [1582]. Formed by heating propionamide with phenyl-hydrogine (Freund, B. 21, 2461). • Plates (from chloroform).

Phenyl-isopropyl-hydrazine C₆H NPr.NH₂ (233²). Formed from sodic@n phenyl-hydrazine and isopropyl bromide (Michaelis a Philips, B. 20, 2485; A. 252, 278). B'HCl. [135²]. Crystalline. Yields a tetrazone [85²]. Phenyl-thiocarbimide forms NPhPr.NH.CS.NHPh. [416].

Acetyl derivative. [102]. Needles. DIPHENYL-PROPYLIDENE DISULPHIDE Mc.C(SPh). [56]. Formed from phenyl-mercaptan and acetone (E. Baumann, B. 19, 2804). Crystals, insol. water, v. sol. alcohol.

DI-PHENYL-PROPYLIDENE DISULPHONE Mc.C(SO,Ph)... [97-j(B.); [182°](F.). Formed by oxidising Mc.C(SPh), (Baumann, B. 19, 2810), and also by treating CH.(SPh), with NaOH and McI (Fromm, A. 253, 162). Crystals, almost insol. cold water.

PHENYL PROPYL KETONE C₁₆H₁₂O (.2. Ph.CO.Pr. Mol. w. 148. (221°). S.G. ¹² (992.

Formation. -1. By distilling calcium butyrate with calcium benzonte (Schmidt a. &ieberg, B. 6, 498). -2. By the action of AlCl, on a mixture of banzene and butyryl chbride (Burcker, Bl. 2) 37, 4). -3. By boiling benzoyl-acetic acid with dilute alcoholic potash (Bacyer a. Perkin, B. 16, 2131; C. J. 45, 181).

Properties. -- Oil. Does not unite with

Properties. — Oil. Does not unite with NaHSO₃. Oxidised by CrO₄ and H.SO₄ to benzoic and propionic acids (Pepoff, B. 6, 560), CrO Cl. forms C₁₀H₁₀O2CrO₂Cl., a brown powder. Phenyl isopropyl ketone Ph.CO.Pr. (200)—

Phenyl isopropyl ketone Ph.CO.Pr. (2009—217°). Formed by distilling calcium isobatyrate with calcium benzoate (Popoff, B. 6, 1255). Liquid. Yields benzoic acid, CO₂, and HOAc on oxidation.

Oxim.—Ph.C(NOH)Pr. [58°]. Plates (from ligroin) (Rattner, B. 20, 506).

PHENYL PROPYL KETONE CARBOXYLIC ACID v. Ethyl-benzoyl-acetic acid, vol. i. p. 482.

Phenyl isopropyl ketone o-carboxylic acid C.H.,O. i.e. Pr.CO.C.H.,CO.H. [121°]. Formed by boiling isopropylidene-phthalide with alcohol and KOHAu (Roser, B. 17, 2777). Crystals.

and KOHAq (Roser, B. 17, 2777). Crystals.

PHENYL: PROPYL METHYL KETONE
CARBOXYLIC*ACID CH.Ph.CHAc.CH...CO.7H.
[99°]. (235° at 40 mm.). Formed by reducing
benzylidene. \$\text{\text{Bacetyl-propionic acid with sodium-}}
manalgam in presence of H.SO.4 (Erdmann, A.
254, 203). Needles. It yields on oxidation

CHMe.O.CO.CO.

PHENYL METHYLENE PROPYL DI-METONE v. Butyryl-acetophenone.

PHENYL-PROPYL METHYL KETONE of CH., CO.CHMe.CH.,Ph. (239°). Formed by distilling calcium acetate with calcium phenylisobutyrate (Von Miller, B. 23, 1884). Oil.

PHENYL PROPYL METHYL KETONE CARBOXYLIC ACID r. BENZYL-METHYL-ACETO-ACETIC ACID, vol. i. p. 25.

Di-phenyl-isopropyl methyl ketone trioarboxylic acid. Ethyl ether of the dinitrile CO_E(C(CII__C_II__CN)__CO_CII__(120^3). Formed from sodium acctoacetic ether and the nitrile I1:2 CH_ClC_H_CN (Gabriel a. Hausmann, B. 22, 2018). Trisms (from alcohol).

Hexa-phonyl-isopropyl methyl ketone carboxylic acid C_eH₁₀O_ei.e. (GPh₂) C(CO.H).CO.CH₂, [160³]. Formed from sodium acetoacetic other and BrCPh₃ (Allen a. Kölliker, A. 227, 111). Crystals (from cher).

PHENYL-PROPYL-PYRAZOLE G₁₂H₁₁N₂ i.e. NPh C(G₃H₁); CH (280°). S.G. ¹⁵ 1 0435. Formed from butyryl-acetic aldehyde and phenylhydrazine (Claisen a. Stylos, B. 21, 1148).

Liquid.

PHENYL PROPYL SULPHONE Ph.SO...Pr. [44°]. Formed by the action of KOHAq at 100° on Ph.SO...CHELCO...H [124°], which is made from a-bromo-butyric acid and sodium benzene sulphinate (Michael a. Palmer, Am. 7, 67; cf. Otto, B. 21, 988). Pearly plates, v. sol. alcohol.

TRI - PHENYL - DI - PROPYL - DI - THIO-BIURET C.S.N.Ph.Pr. [154°]. Formed by the action of aniline (1 mol.) on NPhPr. CSCI (2 mols.) (Pilleter a. Strohl, B. 21, 109). Yollow needles.

PHENYL - PROPYL - THIO - CARBAMIC CHLORIDE NPhPr.CS.Cl. [36°]. Formed from propyl-aniline and CSCl, (Billeter a. Strohl, B 21, 102). Prisms (from ligroin).

DI - PHENYL - ISOPROPYL - THIO - SEMI-CARBAZIDE NHPh.CS.NH.NPhPr. [1169]. Formed from phepyl-thiocarbimide and phonylisopropyl-hydrazine (Michaelis a. Philips, A. 252, 280). Crystalline.

PHENYL-PROPYL-THIO-UBEA C₁₀H_AN_AS i.e. NHPh.CS.NHC₃H_r. [63°]. Formed from aniline and propyl-thio-carbinide and also from propyl-anine and phenyl thiocarbinide (O. Hecht, B. 23, 286). Pearly plates (from dilute alcohol).

Di-phenyl-propyl-thio-urea CSN,HPh,Pr. [1042]. Formed by heating propyl-aniline with phenyl-thio-carbimide on (Billeter a. Stroll, B. 21, 109). Needles.

Di-phenyl-di-propyl-thio-urea CS(NPhPr), [103°]. Formed from propyl-aniline and CSCL (B. a. S.). Large plates.

DI-PHENYL-PROPYL-UREA C, H, N,O i.e. NH_CO.NH.CH_CHPh.CH,Ph. [1122]. Formed from di-phenyl-propylamine hydrochloride and potassium cyanate solution (Freund a. Remse, B. 23, 2861). Needles, sol. alcohol and ether. PHENYL-PYRAZINE. Hexahydride

PHENYL-PYRAZINE. Hexahydride

NPh CH₂CH NH. Formed by heating
bromo-benzene (8 pts.) with pyrazine hexahydride (8 pts.) at 270° (Schmidt a. Wichmann,

B. 24, 8239). Thick liquid, v. sol. water.

Di-phenyl-pyrazine C16H12N2, i.e.

N≪CH:CPh CPh.CH≫N. Iso-indole. [196° cor.]. V.D. 7.95 (Treadwell a. Meyer, B. 16, 342). Formed by the action of cold alcoholic NH. on w-bromo-acetophenoneor on amido-acetophenone (Staedel a. Kleinschmidt, B. 11, 1744; 13, 837; Möhlau, B. 18, 163; Wolff a. Röders, B. 20, 432; Goodeckeneyer, B. 21, 2637). Broad yellow needles (from alcohol). — B'_4H_PtCl_e. Bronzed plates (from HClAq) quickly decomposed by water.

Hexahydride C₁₆H₁₈N₂. [109°] and [123°]. Formed by reducing di-phenyl-pyrazine with Na and isoamyl alcohol. Occurs in two forms. The (a)-variety [123°] crystallises from ligroin in white needles, and yields Bέ 2HCl [c. 310°], B'H,PtCl₂ laq, and a hitrosamine C_h.H_{1c}N_cO_s [143°]. The (β)-variety [109°] crystallises from alcohol in white needles and yields B" 2HCl [c. 295°] and B"H2PtCl, 2aq.

Di-phenyl-pyrazine N CPh.CPh N. [119]. (c. 340°). Formed by distilling the dihydride (M.). Needles (from ligroin), ppd. by adding water to its solution in HClAq. B',H,PtClo

Dihydride N\left\(\frac{CPh.CPh}{CH_2.CH_2}\right\)N. [181°]. Formed by boiling benzil with ethylene-diamine and alcohol (Mason, B. 20, 268; C. J. 55, 97). Prisms (from alcohol), insol. water. Split up by HClAq into the parent substances.

Di-phenyl-pyrazine. Hexahydride .v. DI-PHENYL-DI-ETHYLENE-DIAMINE.

Tetra - phenyl - pyrazine $N \leqslant_{\mathrm{CPh,CPh}}^{\mathrm{CPh;CPh}} N$. Di - tolane - azotide. [241°] (P.); [247°] (G.). Formed by heating benzoïn with ammonium acetate (vol. i. p. 477). Formed also by reducing the di-oxim of di-phenyl-glyoxal in alcoholic solution by sodium-amalgam (Polonowska, B. 21, 489), and by heating benzoic aldehyde with CPhH(NH.).CPhH(NH.) (Grossmann, B. 22, 2302). White needles (from HOAc), v. sl. sol. alcohol. Conc. H.SO, gives a blood-red colour

PHENYL-PYRAZOLE C,H,N, i.e. NPh.CH N-4-CH CH. [11°]. (247° cor.). 1.113. Formed by boiling epichlorhydrin with phenyl-hydrazine and benzene (Balbiano, G. 17, 176; 18, 354). Got also by distilling its tricarboxylic acid (Knorr a Laubmann, B. 22, 180). Oil, sol. alcohol and ether. - B'aH PtCl 2aq: needles, decomposing at 175°.

Ethylo-iodide B'Etl. [117°]. Prisms.

Dihydride NPh.CH₂ CH₂ [52°]. (274° at 754 mm.). Formed from phenyl-hydrazine (120 g.) dissolved in ether (600 g.) by addition of arcolein (50 g.) in ether (100 g.) (Fischer a. Knoevenagel, A. 239, 196). Sl. sol. hot water, Knoevenagel, A. 239, 196). Sl. sol. hot water, v. sol. alcohol, ether, and benzene. Sl. sol. dilute acids, sol. conc. HCl. May be distilled with steam: K.Cr.O, colours its solution in dilute H.SO, reddish violet, or, in very dilute solutions, blue. Gives no indole derivative when fused with ZnCl,.

Reference. — DI-BROMO-PHENYL-PYRAZOLE DI-

165 mm.). Formed from tri-methylene bromide, sodium phenyl-hydrazine, and benzene (Michaelis a. Lampe, B. 24, 3738). Liquid. -B'C, H, N,O, Short yellow needles.

Di-phenyl-pyrazole C, H,2N, i.e.

CH :CH NPh or CH:CPh NPh. [56°]. (336°). Formed by distilling its carboxylic acids (Beyer a. Claisen, B. 20, 2187; Knorr a. Laubmann, B.

21, 1212; 22, 176). White crystals.

**Dihydride ClaHaNa, [136]. Formed by reducing the base. Small needles. An isomeric or identical body [138], got by distilling the state of the control of the contr phenyl-hydrazide of cinnamic aldehyde; differs by fluorescing slightly in alcoholic solution.

Tri-phenyl-pyrazole C₂₁H₁₆N₂. [206²]. A product of the action of phenyl-hydrazine on anhydro - acetophenone-benzil (Japp a. Klinge-mann, C. J. 57, 709). Stellate groups of needles.

Tri-phenyl-pyrazole CH : CPh NPh. [138°]. Got by warming CH Bz, with phenyl-hydrazine (Knorr a, Laubmann, B. 21, 1205). Plates (from ether). Weak base.

Methylo-iodide B'MeI. [176°].

Dihydride CH NNPh. [135°]. Got by reduction or by warming benzylidene-acetophone with phonyl - hydrazine and alcohol. Yields C., H., Br., N., [179°].

PHENYL-PYRAZOLE CARBOXYLIC ACID C₁₀H₈N₂O₂. [220°]. Formed by distilling the tricarboxylic acid (Knorr a. Laubmann, B. 22, 180). Needles (from Aq), v. sol. alcohol, sl. sol. ether. May be sublimed. AgA': amorphous pp. Phenyl-pyrazole dicarboxylic acid

^{V(CO₂H);N} NPh. [256°] (B.); [266°] (C. ▲ R.). Formed by oxidising phenyl-di-methyl-pyrazole or phenyl-methyl-pyrazole carboxylic acid with alkaline KMaO, (Balbiano, R. 23, 1449; Claisen a. Roosen, / 21, 1892). Small white plates in spherical groups (from alcohol).—
(NH₁)A". [212"].—PbA".—AgA".

Methyl ether McA". [128"].

Amide Can HPh(CO.NH.). [190°] Phenyl-pyrazole tri-carboxylic acid

CO.H.C. N. NPh. [184°]. Formed by oxidising phenyl-methyl-pyrazole dicarboxylic acid with alkaline kMnO4 (K. a. L.). White needles (containing aq) (from ether), sol. water and alcohol.—BaHA" aq: plates.

Di-phenyl-pyrazole carboxylic acid CPh NNPh C16H12N2O2

CO.H.C.—NNPh. Got by saponification of its ether, which is obtained by boiling benzoylpyruvic ether CH2Bz.CO.CO2Et (20 pts.) with HOAc (100 pts.) and phenyl-hydrazine (10 pts.) (Beyer a. Claisen, B. 20, 2185). Crystals (containing EtOH), which melt at 185°, v. sol. acctone.

Ethyl ether Eth. [90°] (c. 400°).
Di-phenyl-pyrazole dicarboxylic acid

C₁,H₁₂N₂O₄ i.s. CO₁H.C.C(CO₁H) NPh. [218°]. Got by oxidation of di-phenyl-methyl-pyrazole carboxylic acid (Knorr a. Laubmann, B. 22, 175). Tetra-hydride NPh.CH, CH, (210° at NH,HA". [c. 270°]. Bad" aq. —CaA" 2aq.

References .- OXY- and OXY-AMIDO- PHENYL-PYRAZOLE CARBOXYLIC ACID.

DJ-PRENYL-PYRAZOLONE Oxy-Di-PHENYL-PYRAZOLE PHENYL PYRAZYL METHYL C,N,H,Ph.CO.CH, [122° cor.]. KETONE Formed by heating v-phenyl-pyrazole with AcCl at 150° (Balbiano, G. 19, 136). Small needles. Vields an oxim [131°] and a phenyl-hydrazide [144°].

TETRA - PHENYL - PYRIDAZINE DIHY. DRIDE C22H22N2 i.e. CH.:CPh:NPh ? Formed from desyl-acetophenone, phenyl-hydrazine, and HOAc (Smith, C. J. 57, 649). Yellow needles (from alcohol), v. sol. hot HOAc. According to Klingemann (A. 269, 106), this body is probably phenyl-amido-tri-phenyl-pyrrole, since on boiling with HOAc A yields tetra-

phenyl-pyrrole.

(a)-PHENYL-PYRIDINE $N < \stackrel{CPh.CH}{\leftarrow} CH$: (270°). A product of the distillation of its dicarboxylic acid with lime (Skraup a. Cobenzl, M. 4, 472). Heavy oil. Yields picolinic acid on oxidation.—B'.H.PtCl, 2aq. -Pi crate [c. 170°].

 $N \!\! < \!\! \stackrel{\mathrm{CH.CPh}}{<\!\! \mathrm{CH:CH}} \!\! > \!\! \mathrm{CH}.$ (B)-Phenyl-pyridine (270°). Formed by distilling its carboxylic acid with lime (Skraup a. Cobenzl, M. 4, 453). Got also by heating pyrrole with henzylidene chloride and NaOEt (Ciamician a. Silber, B. 20, 191). Heavy oil. Yields nicotinic acid on oxidation. — B'_II_PICI_3tq. — B'C_II_N_O, [163°]. Groups of yellow needles.

 $N \leqslant_{\mathrm{CH:CH}}^{\mathrm{CH.CH}} \geqslant_{\mathrm{CPh.}}$ (γ)-Phenyl-pyridine [78°]. (275° uncor.). Formed by distilling its tetra-carboxylic acid with lime (Hantzsch, B. 17, 1518). Plates (from water). Yields iso. 17, 1310. Tates (from water). Helds 180 micotinic acid [304°] on oxidation.—3k'_4H_PtCl_.

B'_4H_PtCl_.

Picrate. [196°]. Yellow needles.—
Picrate. [196°]. Yellow needles.

127 mm. Got by reducing the lower (Relly R.

727 mm.). Got by reducing the base (Bally, B. 20, 2590). Strong base, almost insol. water.—B'HCl. Needles.—B'₂H₂PtCl₂. [204°-207].

v-Phenyl-pyridine hexahydride

NPh CH₂CH₂CH₂ Phenyl-piperidine. (249°). Formed by heating piperidine with iodobenzene or bromo-benzene at 260° (Lellmann, B. 20, 680; 21, 2279. Alkaline oil, v. sol. alcohol and ether. -B'2H.PtCl, 2aq: needles or plates. -B'H, Cr, O,: plates.

References .- AMIDO- and NITRO- PHENYL-

Di-(α)-phenyl-pyridine C₁₇H₁₃N i.e.

N CPh.CH CH. [82°] (P. a. S.); [73°] (D.). Formed by distilling its carboxylic acids with Formed by distilling its carboxylic acids with soda-lime (Panl a. Strasser, B. 20, 2764; Doebner, A. 243, 121). Yellow needles, v. sol. alcohol. Yields an oily hexahydride.— B',H,PtCl. [205°].— B'HAuCl. [202°].— B',H,Cr,O₁₁. Orange-red needles.

Methylo-iodide B'MeI. [203°]. Tri-phenyl-pyridine O₂H₁₁N. [135°]. Formed by passing NH, through acetophenone, and adding P.O. (Engler, B. 6, 639; 19, 40; A. 238, 27).— B, H,PtCl.

Reference.—Oxy-Phenyl-Pyriding.

Vol. IV.

PHENYL-PYRIDINE o-CARBOXYLIC ACID

C₁₂H₀NO₂ i.e. N CH:C(C₀H₄·OO₂H) CH.CH f185%. Formed by heating the dicarboxylic acid at 185° (Skraup a. Cobenzi, M. 4, 450). Needles, sl. sol. cold water. Yields nicotinic acid on oxidation, -CaA', 2aq: long needles, v. sol. cold water.

(a)-Phenyl-pyridine dicarboxylic acid $C_{13}H_{p}NQ_{4}$ i.e. $N \leqslant \begin{array}{c} C(C_{0}H_{4},CO_{3}H);C,CO_{2}H \\ CH \end{array}$ [280°-235°]. Formed by oxidation of (a)-naphtho-quinoline (Skraup a. Cohenzl, M. 4, 463). Minute crystals, gives off indigo-blue vapours when heated. When distilled with CaO it yields (a)-pkenyl-pyridine and the compound C, H, NO [140-142] (315°), which crystallises from alrohol in yellow plate and yields P'_H_PtCl_

Yields a di-bromo-derivative $|205^\circ|$. Salts. — CaA" 2aq. — CuA" 4aq: violet crystalline pp. — Ag.A" 1\[\]aq. — H.A" HCl. — (I\[\]A")_2\[\]_1\[\]P(C\[\]_3\]aq.

(B)-Phenyl-pyridine dicarboxylic acid

 $N \leqslant \stackrel{C(CO,H):C.C_6H_4,CO_2H[1:2]}{CH}$, [207°]. Formed

by oxidation of (B) naphthoquinoline (Skraup a. Cohenzl, M. 4, 442). Prisms (containing aq), sl. sol. cold water. Salts. — HA'HCl. sl. sol. cold water. Salts. — HA'HCl. (HA'), H.PtCl. $2\frac{1}{2}nq.$ — $K_2A''3aq.$ — KHA''2aq.— CaA" 3aq. BaA" 4]aq. - CuA" 4aq. - Cu₂H₂A"₄.

-AgH₄A"₂.

Sulphonic acid C, H, NSO, i.e. $N \leqslant C(CO,H):C.C_0H_3(SO_3H)(CO_2H)[1:2:6]$ CH . CH :CH

Formed, as well as C₁₂H₆(SO₂H)NO aq, by *xidation of (s)-naphtho-quinoline sulphonic acid with alkaline KMnO₄ (Immerheiser, B. 22, 405). Crystals (from water). - K_aA''', - Ba₂H₃A'''₄, - Pb₄A'''₂(OH)₂- Ag₃A''' (dried at 100'). The by-product C₁₂H₄(SO₃H)NO aq yields KA'aq, BaA'₂2aq, PbA'₂3aq, AgA'aq, an oxim [290'] and a phenyl-hydrazide [c. 295°].

Phenyl-pyridine dicarboxylic acid

 $N \leqslant_{CH,C(CO_2H_1)}^{CH;C(CO_2H_1)} \geqslant_{CPh,[230^\circ] \text{ (hydrated); [246^\circ]}}$ (anhydrous). Formed by heating the tetra-carboxylic acid at 170° (Weber, A. 241, 13). Greenish-yellow plates (containing aq. — CuA" 2nq ; blue pp.

 (γ) -Phenyl-pyridine tetra-carboxylic acid $N \leqslant \stackrel{C(CO_1H).C(CO_2H)}{C(CO_2H).C(CO_2H)} \geqslant CPh.$ [207°]. Formed by oxidation of the phenyl-di-methyl-pyridine dicarboxylic acid, which is got from acetoacetic ether, NH3, and benzoic aldehyde (Hantzsch, B. 17, 1515). Crystals (containing 3aq), v. sol. water. KH A aq: small prisms or pyramids, sl. sol. cold water. -Ba, (NH4)2A'v2 Gaq: minute tables. -Cu_zA'v 7aq.

Di-phenyl-pyridine (γ)-carboxylic acid N < CPh.CH > C.CO.H. [275°]. Formed by

heating (CH₂Bz)₂C(CO₂H)₂ with alcoholic NH, at 120° (Paal a. Strasser, B. 20, 2761). Needles (from alcohol). -- AgA': pp., sl. sol. hot water. Dihydride C18H13NO2 i.e.

NH CPh:CH CH.CO.H. Crystalline flakes. -NH,A'. [270°]. Formed from (CH,Bz) CH,CO,H and alcoholic NH, in the cold. Needles, v. sol. . water.

Hexahydride NH CHPh.CH CH.CO2H. [889°]. Formed,

in small quantity, when di-benzoyl-di-methylmalonic acid is heated with alcoholic NH, at 120° (P. a. S.). Crystals, v. sl. sol. water. Yields a nitrosamine [159°].

Di-phenyl-pyridine tricarboxylic acid

 $N \leqslant \frac{C(C_eH_+,CO_2H):C.CO_2H}{CPh.CH}$ [250°]. Formed by oxidising phenyl-naphthoquinoline carboxylic acid with alkaline KMnO, below 50° (Doebner, A. 249, 120). Needles (from dilute alcohol).-Ag.A'": white flocculent pp.

At 100° the chief product is phenylene phenylyridylene ketone carboxylic acid C, 11, NO [226°], which on distillation with soda-lime yields CO C.H. PhN [68°], which forms an oxim [84°]

and B'2CrO3.

Reference. - OXY-PHENYL-PYRIDINE CARBOXYLIC

PHENYL PYRIDYL KETONE C_{1.}H_nNO i.e. C_{2.}H_{5.}CO.C₅H₁N. (307°). Formed by heating its carboxylic acid (Bernthsen a, Mettegang, B.

18 carboxyno acid (Derminen a. metergeng, γ. 20, 1209). Liquid. Yields a phenyl-hydrazide [143·5°].—Β'₂H₂PtCl₂.

PHENYL (β)-PYRIDYL KETONE CARBOXYLIC ACID 0₂H₂, CO.2, H. [147°]. Formed from quinolinic anhydride, benzene, and AlCl, (Bernthsen a. Mettegang, B. 20, 1209). Prisms, v. e. sol. hot water.

DI-PHENYL-PYRONE co<ch:CPh>o.

[139.5°]. Formed by heating its carboxylic acid (Feist, B. 23, 8734). Got also by heating dehydro-benzoyl-acetic acid with HClAq at 245°. Needles resembling asbestos (from benzene). Its solution in conc. H.SO, exhibits violet fluorescence. Alcoholic NH, converts it, on heating, into oxy-di-phenyl-pyridine.
DI-PHENYL-PYRONE CARBOXYLIC ACID

CO C(CO₂H):CPh O. [201°]. Formed by

warming chloro-dehydro-benzoyl-acetio acid (1 pt.) in H.SO. (3 pts.) at 140° (Feist, B. 23, 8730). Small crystals (from benzene), v. sol. chloroforr. NH, A. [135°].—BaA', 6aq.— Ag₂A'₂AgNO₂: curdy pp.
Di-phenyl-pyrone dicarboxylic ether

CO C(CO,Et):CPh O. [140°]. Formed by allowing a mixture of cupric benzoyl-acetic ether (24 g.), COCl. (10 g.), and toluene (40 g.) to stand for six weeks (F.). Got also from acetone dicarboxylic ether, Et,O, Na, and BzCl (Dünschmann a. Pechmann, A. 261, 189). Plates, v. sol. most solvents.

PHENYL-PYROTARTARIC ACID

C.H. CH, CH (CO.H) CH .CO.H. Benzyl-succinic acid. [161°]. Got by heating phenyl-propane tricarboxylic acid and by reducing phenyl-ita-conic acid (Bischoff, B. 23, 653; Fittig a. Roeders, A. 256, 87; cf. Baeyer a. Perkin, B. 17, 449). White plates, sl. sol. cold water. hydride (102°).—BaA" laq.—CaA".—Ag₂A".

Phenyl-pyrotartaric acid
CO,H.C.H.Ph.C.H.M. CO.

CO.H.CHPh.CHMe.CO.H. Two varieties [171°] and [198°] are formed by saponifying the product of the reaction of NaOEt on a mixture of a-cyano-propionic acid and a-bromo-phenyl-

acetic ether (Zelinsky a. Buchstab, B. 24, 1877). At 320° it forms an anhydride which on treatment with water yields a mixture of the two isomeric phenyl-methyl-succinic acids.

Reference. -- Oxy-amido-phenyl-pyrotartario

PHENYL-PYROXIMIDINE DIHYDRIDE

CH₂<CH₂·O CPh. Formed from γ-bromopropyl-benzamide by shaking with hot water (Gabriel, B. 24, 3214). Liquid, sl. sol. cold water.—B'₂H₂PtCl_e. [185°].—B'C_eH₄N₃O₇. [151°].

NH CPh:CH DI-PHENYL-PYRROLE

[143°]. Formed by the action of alcoholic potash on its carboxylic ether (Paal, B. 21, 3061). Got also by heating the dicarboxylic acid C,NH,(C,H,CQ,H)2 with lime (Baumann, B. 20, 1490). Plates (from HOAc or dilute alcohol). Forms a red solution in H.SO.. Colours pinewood, moistened with HClAq, red.

Tri-phenyl-pyrrole NPh CPh.CH Formed by heating its carboxylic acid or its dicarboxylic acid $C_1NH_2Ph(C_2H_1,CO_2H)_2$ with lime (P.; B.). Needles, sl. sol. ether and alcohol.

Tri-phenyl-pyrrole NH<CPh:CPh Formed by heating desyl-acetophenone with alcoholic NH, at 150° (Smith, C. J. 57, 645). Slender needles with violet fluorescence.

Tetra-phenyl-pyrrole C28II21N i.e.

NH CPh: (Ph [214·5°]. Formed from both bidesyls by heating with alcoholic NH, at 150° (Garrett, B. 21, 3107; Fehrlin, B. 22, 553; Magnanini a. Angeli, B. 22, 855). Got also by distilling its phenyl-v-amido- derivative (Klingemann, A. 269, 122). Needles or plates.

Acety derivative. [226°]. Needles.
Tetra-phenyl-pyrole NPh CPh:CH:

[197°]. Formed by boiling desyl-acctophenone with aniline and HOAc (Smith, C. J. 57, 646). White silky needles, v. sl. sol. cold alcohol. DI-PHENYL-PYRROLE CARBOXYLIC ACID

NH<CPh:C.CO₂H [261°]. Formed by saponifring the ether, which is got by the action of alcoholic NH, or of boiling NH,OAc and HOAc on di- β -benzoyl-propionic ether (Kapf a. Paal, B. 21, 1491, 3061). Orange needles, sl. sol. alcohol.

Ethyl ether EtA'. [159°]. Needles. Amide C₁₇H₁₁N₂O. [2170]

A mude C₁,H₁,N₂O. [217].

Di-phenyl-pyrole dio-osrboxylie acid dio-osrboxylie acid dio-osrboxylie acid the constant of t tallising from HOAc.

Tri-phenyl-pyrrole carboxylic acid
NPh CPh:C.CO.H. [273°]. Formed by saponifying the ether, which is got by boiling dibenzoyl-propionic ether with aniline and HOAc (Paal, B. 21, 3061). Needles (from HOAc). Ethyl ether Eth. [170°]. Needles.

Tri-phenyl-pyrrole di-earboxydic acid

NPh C(C,H,CO,H);CH
C(C,H,CO,H);OH
[295°]. Formed ty

parming C.H.(CO.C.H.CO.H), with aniline Baumann, B. 20, 1487). Crystals, insol. water.

ig A": bulky pp. Ethyl ether Et.A". [122°]. Needles. DI - a - PHENYL - 6 - PYRROYL - PROPIONIC CID C,H,N.CO.CH, CPh, CO.H. [216°]. Formed by saponification of di-phenyl-pyrrylerotolactone CH:C(C,H,N) O [184°] which is got by warming (a)-pyrryl methyl ketone with benzil and conc. KOHAq (Angeli, B. 23, 1356). Colourless crystals, almost insol. water. - KA'. -AA': light-yellow pp.

PHENYL PYRRYL KETONE C,H,NO i.e. NC,H,.CO.C,H,. [78°]. Formed by heating pyrrole with NaOBz and Bz,O (Ciamician a. Dennstedt, B. 17, 2955). Yields Ci, H, AgNO.
PHENYL-PYRUVIC ACID v. PHENYL-GLY-

CIDIC ACID.

PHENYL-QUINAZOLINE C.H. CH:N

[101°]. Got by distilling o-amido-benzyl-benzamide (Gabriel a. Jansen, B. 23, 2810). Yellow needles. Weak base.

Phenyl-quinazoline. Dihydride.

C₁₁H₁₂N₂ i.e. C₄H₄CH NPh [95°]. Formed by reducing [1:2]C.H.(NO.).CH. NPh.CHO with zine and HClAq (Paal a. Busch, B. 22, 2686; Donner, Ph. [3] 20, 43). Six-sided tables (from ether-ligroin), almost insol. water and alkalis. Split up into aniline and benzonitrile by heating with zinc-dust .- B'HCl 2aq. [80°] when hydrawith zinc-dust.—BEG 24d, [60] when hydrated; [221°] when anhydrous. Concentrion needles, sol. water.—B'HSnOl, [130°-134°]. White crystals.—B'₂H₂PtCl_e. [208°]. Yellow crystals.—B'₂H₂SO₄2aq. [79°]. Melts at 140°-143° when anhydrous.

Methylo-iodide B'MeI. [1570°] and [180°]. -B'MeI2. [157°]. Golden plates.

Tetrahydride C.H. NIh. (117°). Got by reduction. Needles. Yields a crystal-line acetyl derivative and a brick-red nitros-

Di-phenyl-quinazoline. Dihydride. C. H. N. i.e. C. H. C. N. Ph. [115°]. Formed by reduction of the benzoyl derivative of o-nitrobenzyl-aniline in HOAc with tin and HCl (Lellmann a. Stickel, B. 18, 1608). Small needles, v. sol. alcohol. - B'HCl : silky needles.

Reference .- OXY-PHENYL-QUINAZOLINE. (B. 2)-PHENYL-QUINOLINE

ÇPĥ:CH.Ç.CH:ÇH OH :CH.C.N = CH. p-Phenyl-quinoline. [111°]. [260° at 77 mm.). S.G. 22 1.1945. Prepared by heating p-amido-diphenyl with glycerin, nitro-penzene, and H.SO, (La Coste, B. 15, 562; A. 230, 8). Trimetric plates (from ether). B'_H_Ptcl. Orange crystalline powder. — B'_H_Cr_O, [136°]. — Tartrate B'C,H_O, 3aq. 153°]. Needles

Methylo-iodide B'MeI 2aq. [194°]. Ethylo-iodide B'Etl 2aq. [169°].

Tetrahydride C.H., PhN. Got by reduction. Unstable pp. Yields a nitrosamine Z.H., Ph(NO)N [112°], an acetyl derivative [100°], and a lenzoyl derivative [137°].—B'HCl llag. 204°].—B'C., H.N., O., [165°].

(B. 4)-Phenyl-quinoline CH:CH .C.CH:CH CH:CH o Phenyl-quinoline. (273° at 80 mm.). Got in . like manner, using o-amido-diphenyl (C.). Oil, with yellowish-green fluorescence. B',H,PtCl. -B.H.Cr.O., [126°]. Orange plates.

Methylo-iodide B'Mel. [163°]. Crystals,

v. sol. water. - B'_Me_PtCl, [193°].

(Py. 1)-Phenyl-quinoline $C_vH_i < CPh:CH_N = CH$ [62°]. Got by heating its carboxylic acid (Königs a. Nef. B. 19, 2430). Needles (from ether or ligroin). Solutions of its sulphate and hydrochloride fluoresce blue. BH, CrO.: needles.-B'2122PtCl6: yellow four-sided tables.

(Py. 2) - Phenyl quinoline CaH CH: CPh Formed by adding a little NaOH to a solution of o-amido-benzoic aldehyde and phenyl-acetic aldehyde in dilute aicohol (Friedländer a. Gohring, B. 16, 4836). Oil, sparingly volatile with steam. - B'HCl. [93°]. - B'2H,PtCl.

(Py. 3) - Phenyl - quinoline CoH: CH: NCPh. [86°]. (above 360°)

Formation .- 1. By heating cinnamic aldehyde (30 pts.) with aniline (20 pts.) and conc. HClAq (20 pts.) for two hours at 210° (Grimaux, C. R. 96, 584; Doebner a. Miller, B. 16, 1665; 19, 1194). -- 2. By warming o amido - benzoic aldehyde with acetophenone, dilute alcohol, and a little NaOH (Friedländer a. Gohring, B. 16, 1835).-3. By distilling m-oxy-phenyl-quinoline or di-oxy-phenyl-quinoline with zinc-dust (Miller a. Kinkelin, B. 18, 1908; Weidel, M. 9, 151,... 4. By distilling its carboxylic acid with soda-lime (Deebner, B. 20, 280; A. 242, 294; Pfitzinger, J. pr. [2] 38, 583).

Properties. - Silky needles (from dilute alcohol), sol. ether, sl. sol. water. Yields NHB&C,H,CO2H [1:2] [182°] on oxidation by KMnO, in acid solution.

KMnO, in acid solution.

Salts.—B'.H.PiCl₀ 2aq.—B'HAuCl, [160°].

—(B'HCl).AuCl, [204°]. Needles.—B'H.Cr.O,; stable golden plates.—B'C.H.N.O, [188°].

Alkylo-todides B'McI. [197°].—B'ELI. [195°].—B'ELI. [195°].—B'ELI. [195°].—B'ELI. [197°].—God and the stable of the

reducing the base with tin and HClAq (Dochner, B. 19, 1198). Oil, yielding an oily nitrosamine. --BHCl. Needles (from alcohol), v. sl. sol. water. (Py. 1,3)-Di-phenyl-quinoline

 $C_aH_i < N - CPh$. [112°]. Formed by heating the anilide of CH₁Bz₂ with H₂SO₄ (Beyer, B. 20, 1772). Mass of white crystals. -B'₂H₂PtCl₄ 2aq. - B'H.SO. Needles, v. sl. sol. dilute H.SO. (Py. 2,3)-Di-phenyl-quinoline

 $C_sH_i < N - CPh$. [96°]. (c. 420°). Formed by reducing [1:2] CaH4(NO2).CH2.CHPh.CO.CaH4 with iron and HOAc Buddeberg, B. 23, 2075). Large crystals, sol. alcohol.—B'.H.PtCl.

(Py. 2)-PHENYL-ISOQUINÖLINI

C₁₃H₁₁N i.e. C₆H₄ CH:ÇPh. [105°]. Obtained by reduction of the (Py. 4)-chloro-derivative by heating it with HI and P at 170° for three hours; also by distilling phthalimide with zinc-dust (Gabriel, B. 18, 3477). Rhombic plates. Slightly volatile with steam.—B',H,Cl,PtCl,: needles. Tetrahydride C.H. CH. CHPh.

•48°]. Formed by reduction of an alcoholic solution of the (Py.)-mono- or di- chloro-derivatives by boiling with (3 p.c.) sodium-amalgam (Gabriel, B. 18, 3479). Crystals, v. sol. alcohol.

References. - AMIDO-, CHLORO-, CHLORO-NITRO-, NITRO-, OXY-AMIDO-, and OXY- PHENYL-OHINGLINE.

(Py. 1) - PHENYL - QUINOLINE (Py. 3)CARBOXYLIC ACID C16H11NO i.e. .

C.H. CPh:CH [171°]. Got by oxidation of phenyl - methyl - quinoline - phthalone with chromic acid mixture (Kænigs a. Nef, B. 19, 2428). Yellow needles (from dilute alcohol), sol. acids and alkalis.

acids and alkalis. (Py. 3)-Phenyl-quincline (Py. 1)-carboxylic acid $C_0H_1 < C_0(C_0 H_1) : CH = OPh$. [207°]. Formed by warming pyruvic acid with Benzoic aldehyde, aniline, and alcohol (Doebner, B. 20, 280; A. 142, 291). Formed also by heating isatin with acetophenone and alcoholic potash (Pfitzinger, J. pr. [2] 83, 538). Needles, m. sol. cold_alcohol. Yields phenyl-quinoline [84°] on distillation with soda-lime. — (HA')_H_2HCl₀. — PbA'₂aq.— $\operatorname{CuA'_2aq}$.— $\operatorname{ZnA'_2aq}$.— $\operatorname{AgA'}$: white pp. **Phenyl** - quinoline - o - di - carboxylic acid

 $C_9H_4(C_9H_8)N(CO_2H)_2$ i.e. $C_8H_4 < CPh:C.CO_2H = C.CO_2H$ Formed by oxidation of phenyl-acridine with

Salts .- BaA"4aq : glistening needles (Claus a. Nicolaysen, B. 18, 2706).

(Py. 2,3) - Di-phenyl-quinoline carboxylic acid C_sH₄ C(CO₂H):CPh . [191°]. Formed by the action of isatin and alcoholic potash on deoxybenzoïn (Pfitzinger, J. pr. [2] 38, 583). Needles, insol. water, v. sol. hot alcohol.

(Py. 3)-PHENYL-QUINOLINE (B. 2)-SUL-PHONIC ACID SO, H.C.CH.C.CH.;CH HC:CH.C.N=CPh together with the more soluble (B. 3)-sulphonic acid, by heating (Py. 3)-phenyl-quinoline with HSO₄ and SO₄ at 100° (Murmann, M. 13, 60).— H₂SO, and SO₂ at 100 (Murmann, Plates, sk-sol, water, almost insol. alcohol. Gives oxy-phenyl-quinoline [238°] when fused with potash at 250°.—BaA'2: plates.—NII,A': plates. -AgA': granules.

(Py. 3) - Phenyl - quinoline (B. 3) - sulphonic acid. Formed as above (M.). Granules. Yields oxy - phenyl - quinoline [156°] on fusion with potash. - KA'aq. - BaA', 11aq: needles. -

AgA' 1 aq: needles.

(B. 2) - Phenyl - quinoline p-sulphonic acid C13H11NSO3 i.e. [1:4]SO3H.C6H1.C:CH.C.CH:CH HC:CH.C.N=CH

Formed, together with the following more soluble isomeride, by sulphonation of p-phenyl-quinoline (La Coste a. Sorger, A. 230, 30). Needles (containing 2aq). Turns brown, without fusion, at 300°. Alkaline KMnO, gives quinolinic aoid and p-sulpl o-benzoic acid.—NH, A'. [above 310°].—

NaA'aq.— $\operatorname{HgA'}_2$: white pp.
(B. 9) - Phenyl - quinoline (β) - sulphonic acid. Formed as above. Plates (containing aq), not melted at 300°.—NH,A': small scales.

PHENYL-DIQUINOLYL-METHANE. Octohydride CHPh(CoH10N) [153°]. Formed from quinoline tetrahydride, benzoic aldehyde, and ZnCl₂ in alcohol (Einhorn, B. 19, 1243). Its

Di-phenyl-(B. 1)-quinolyl-methane
CHPh_C:CH.C.CH:CH
HC:CH.C.N=CH
104°]. Formed [104°]. Formed by Skraup's method from amido-tri-phenyl-methane (Fischer a. Fränkel, B. 19, 749; A. 241, 364). Prisms, v. sol. alcohol. Yields a nitro-derivative [213°]. -B'2H_PtCl, (dried at 100°).

DI-PHENYL-(Py. 3) QUINOLYL-UREA C,H,NNPh.CO,NHPh. [150°]. Formed by heating carbostyril with phenyl isocyanate and benzene at 220° (Goldschmidt a. Meissler, B. 23, 276). Needles (from benzene), sol. HClAq and re-ppd. by NH,.

DI-PHENYL-QUINONE C18H12O2 i.e.

CPh CO.CH CPh. [214°]. Formed by heating phenyl methyl diketone with NaOHAq and a little K_3 FeCy₈ at 100° (Müller a. Pechmunn, B. 22, 2130). Orange-yellow plates, m. sol. benzene. Zinc-dust and HOAc reduce it to di-phenylhydroquinone [219°].

DI-PHENYL-QUINOXALINE C.H. N:CPh [126°]. Formed by heating benzoin with ophenylene-diamine in the air at 165° (Fischer. B. 24, 720). Needles.

Dihydride C.H. NH.CHPh [149°]. Formed by heating benzoin with o-phonylenediamine at 165° with exclusion of air. Prisms. Its solutions in ether and benzene fluoresce yellowish-green.

Phenylo-hydroxide $C_{i}H_{4} < NPh(OH):CPh \\ CPh$ [135°].

Formed from benzil and o-phenylese-phenyldiamine (Kehrmann a. Messinger, B. 24, 1239). - C₂₈H₁₀N₂ClFeCl₃. r Golden prisms, m. sol. cold water, insol, ether. — (C₈₅H₁₉N₂Cl)₂PtCl₄. — C₂₅H₁₉N₂HgCl₃. Yellow scales.

Tri-phenyl-quinoxaline. Dileydride

C_eH₄ NPh.(HPh. [117°]. Got by heating

benzoin with a-phenylene-phenyl-diamine in a sealed tube at 175° (Kehrmann a. Messinger, B. 24, 1875). Crystalline, v. sol. ether. Its solutions fluoresce bluish-green.

Tetra-phenyl-diquinoxaline, so-called. CPh:N.C.CH:C.N:CPh CPh:N.C.CH:C.N:CPh [289°]. Formed from tetra-amido-benzene and benzil (Nietzki a Müller, B. 22, 446). V. sol. hot HOAc. Forms a blue solution in conc. H.SO.

DI-PHENYL-QUINOXALINE CARBOXYLIC **ACID** $C_{21}H_{14}N_2O_2$, i.e. $\left[4\frac{2}{1}\right]C_9H_3(CO_2H) < N:CPh$ [288°]. Formed by mixing benzil and di-amidobenzoic acid, both dissolved in hot HOAc (Zehra, B. 23, 3627). Yellow plates or needles. - BaA'₂3aq: needles, sl. sol. hot vater.

· Ethyl ether EtA'. [151°]. Needles. TETRA-PHENYL-DIQUINOXALYL C., H., N., i.e. CPh:N C.H. C.H. N:CPh. [above 270°]. Formed by mixing acetic acid solutions of benzil and tetra-amido-diphenyl {0,H₂(NH₂);[1:8:4]}, (Brunner a. Witt, #: 20, 1026). Crystals (from phenol-HOAc). Forms a bright-red solution in conc. H₂SO

16. H₂50. PHENYL SELENIDE v. Organic compounds of SELENIUM.

TETRA - PHENYL - SILICANE v. Organic compounds of Silicon

PHENYL SILICATE Si(OPh), [48°]. (420°). Prepared by heating phenol with SiCl,; the yield being 78 p.c. of the theoretical amount (Hertkorn, B. 18, 1679). Long colourless prisms, r. sol. alcohol. Decomposed by hot water into phenol and silicic acid. Boiling alcohol forms ethyl silicates and phenol.

TRI-PHENYL-STIBINE v. vol. i. p. 294 PHENYL-STYRYL-HYDRAZINE C, H16N, i.c. CHPh:CH.CH., NPh.NH₂. [54°]. Formed from styryl bromide and sodium phenyl-hydrazide (Michaelis a. Claessen, B. 22, 2239). Crystals, y. sol. alcohol and ether.

PHENYL-STYRYL KETONE v. BENZYLIDENE-ACETOPHENONE. Its carboxylic other is described as Benzylidene-benzoyl-acetic ether, vol. i. p. 481.

PHENYL - SUCCINIC ACID C10H10O4, i.e. CO_H.CHPh.CH_.CO_H. [167°].

Formation. - 1. By saponification of the nitrile which is got from ω-chloro-styrene and KCy (Rügheimer, B. 14, 428). - 2. By saponitication of the product of the action of a-bromophenyl-acetic ether on sodium acetoacetic ether (R.). - 3. At 191° from CO.H.CHPh.CH(CO.H)., got from a-chloro-phenyl-acetic ether and sodium malonic ether (Spiegel, B. 14, 873, 1693; A. 219, 32; Alexander, A. 258, 74).—4. From hydro-

cornicularic acid by potash-fusion (S.).

Properties. Needles, sol. hot water and alcohel, sl. sol. chloroform. Br and PBr, yield a bromo- derivative [119"] converted by hot water into phenyl-maleic acid.

mo pnenyi-nate and. Sulty-CaN', $Anhydride\ C_{10}\Pi_1Q_3$ [c. 54°]. (a)-Di-phenyl-succinic acid $C_{11}\Pi_1Q_4$ i.e. (C.)-H.CHPh.CHPh.CO.H. [222°] (when dry); [183°] (when hydrated). H.C. 1,848,300 (Ossipofi, C, R, 149, 223). (S. (alcohol) 41 at 21°.

Formation -1. By heating a bromo-phenylacetic acid with KCy (Franchimont, B. 5, 1048). Together with the isomeric (β) acid, by reduction of di-phenyl-maleic anhydride with sodium-amalgam or Zn and HCl. Separated through the sparing solubility of the Ba salt (Reimer, B. 14, 1802; Anschütz, A. 259, 67). 8. By heating the (B)-isomeride with barytawater at 200° (R.).

Properties. - Prisms (containing aq) or needles (from dilute HOAc). Yields di-phenyl-ethane and di-phenyl-ethylene when distilled with lime.

HClAq at 200° converts it into the (β) acid. Salts.—BaA" 2aq. S. 32 at 18°.—BaA" 4aq. -Ag₂A": white pp.

Mono-ethyl ether HEtA". [140].

Di-ethyl ether Et.A". [81]. Needles. Anhydride $C_{10}H_{12}O_3$. [116]. (240° at 11 mm.). Formed when either of the two s-diphenyl-succinic acids is heated. Got also by

heating the (a)-acid with AcCl at 120° (Till-manns, A. 258, 87). Trimetric crystals; a:b:c = 508:1: 546. V. sol. chloroform. Yields the (a) acid on boiling with water, and a mixture of (a)- acid (80 p.c.) and (β)- acid (14 p.c.) when treated with KOHAq.

Nitrile CN.CHPh.CHPh.CN. (160°1. Formed, together with the (β) - isomeride by heating phenyl-acetonitrile with mandelic nitrile and alcoholic KCy at 55° (Chalanay a. Knoevena-gel, B. 25, 289). V. e. sol. alcohol. Converted into the (B)- isomeride by boiling with HOAc.

Phenylimide C., H., NO. [231°]. Got by heating either the (a)- or the (b)- anhydride with aniline.

Phenyl - amic acid C₂H₁₀NO₄ i.e. CO.H.CNPh.CHPh.CO.NHPh. [220°]. Got by boiling the pheuylimide with baryta (Anschütz a. Bendix, A. 259, 92).

(B)-Di-phenyl-succinic acid CO.H.CHPh.CHPh.CO.H. [230°]. H.C. 1,822,900. S. (aleohol) 1924 at 215.

Formation.-1. By heating its nitrile with HelAq at 200°.-2. By reduction of di-phenylmaleic anhydride. 3. By heating the a-isomeride with HCAq at 200°.

Properties.—Needles, sol. alcohol, sl. sol. bergene, insol. water. On distillation in vacuo at 250° it yields a mixture of the (a)-anhydride (89 p.c.) and the (β)- anhydride (11 p.c.).

Reactions. 1. Yields s-di-phenyl-ethane and di-phenyl-ethylene on distillation with lime (Reimer, B. 14, 1802). 2. Baryta-water at 200° converts it into the (a)- isomeride.

Salts.--BaA" 7aq. S. 21 at c. 18°, --AgA". Ethyl ether Et, A". [141°]. Noedles.

Anhydride CHPh.CO O. Formed by heating the (B)- acid with AcCl at 100°, and also by the action of AcCl on its salts. When boiled with water it yields the (a)- acid (75 p.c.) and some (3)- acid (25 p.c.). Cold KOHAq forms only the (β) -acid. On heating with aniline

Diphensuccindone

Formed by heating the acid (5 g.) with conc. H.SO₄ (8 g.) until dissolved, and then pouring n₂, N₂ to 8.7 mm dissoived, and then pouring into water (Roser, A. 247, 153). White crystals, insol. water, sol. alcohol. Yields a dioxim C₁₀H₁₀(NOH)₂ [254°] and a phenyl-hydrazide C₁₆H₁₀(N.HPh)₂ [c. 265°]. Reduced by HI and P to C₁₀H₁₁ [100°].

Nitrile CN.CHPh.CHPh.CN. [280°], Accompanies the (a)- isomeride (v. supra). Colour-

less needles, sol. hot alcohol.

Tetra-phenyl-succinic acid CO₂H.CPh₂.CPh₂.CO₂H. [262°]. Formed by heating a chloro-di-phenyl acetic ether with finely-divided silver at 125° (Bickel, B. 22, 1538). Insol. water, v. sol. alcohol and ether.

Ethyl ether Et.A". [89°]. Nitrile CN.CPh. CPh. CN. [c. 230°]. Formed by the action of NaOEt and I on diphenyl-acetonitrile (Auwers a. V. Meyer, B. 22, 1227; cf. Anschütz a. Romig, A. 238, 849). Formed also by the action of nitrous acid on diphenyl-acetonitrile (Neure, A. 250, 148). Flat needles (from HOAc), v. sl. sol. hot alcohol. Liquefied by heating for a long time at 180°.

Phenyl-isosuccinic acid v. Benzyl-malonic

References. -- NITEO. and OXY. PHENYL-SUCCINIC ACIDS.

DI-PHENYL-SUCCINIMIDINE C, HIN, i.s. C.H. C(NH) NPh. Formed from ethylene

cyanide and aniline hydrochloride at 154° (Blochmann, B. 20, 1856). Greyish-yellow crystals, insol. water. Yields the phenylimide of succinic acid when boiled with HClAq.—B'H.PiCl.,—B'H.SO.,—B'HBr.—B'HI.

PHENYL-SULPHAMIC ACID C.H. NSO, i.e. C.H.NH.SO.H. Formed as a salt from ClSO.H (1 mol.), aniline (3 mols.) and chloroform in the cold. Got also by the action of solid fuming sulphuric acid on aniline in CHCl, at allow temperature (Wagner, B. 19, 1157; Traube, B. 23, 1655; 24, 360).—NaA'.—KA': leathets, sol. hot alcohol.—BaA', 2aq: leaflets or needles, sol. hot water. Decomposed by acids into aniline and H.SO. - NH.PhHA'. [192°]. Plates.

PHENYL SULPHATE.

Hydrogen phenyk sulphate C.H.O.SO.OH. Phenyl-sulphuric acid. Occurs in urine of horses, men, and dogs (Baumann, B. 9, 55; 11, 1907; H. 2, 335), the quantity being generally increased by administration of phenol. The K salt is formed by adding K.S.O. (125 pts.) to a solution of phenol (100 pts.) and KOH (60 pts.) in water (90 pts.) at 65°. The free seid quickly splits up, in aqueous or alcoholic solution, into phenol and H.SO. - KA'. S. 14 at 15°. Plates (from alcohol). Not attacked by potash. The dry salt changes at 150°-160° into phenol psulphonic acid.—BaA', 3aq: needles.
DI-PHENYL SULPHAZIDE v. Phenyl-

hydraside of Benzene sulphonic acid.

DI-PHENYL SULPHIDE C12H10S i.e. Ph2S.

Mol. w. 186. (293°). S.G. 1·119.

Formation.—1. By the dry distillation of

sodium benzene sulphonate (Stenhouse, Pr. 14, 351; A. 140, 288). 2. From S(C, H, NH.), by elimination of NH₂ by the diazo-reaction (Krafft, B. 7, 384, 1164).—3. By distilling Pb(Sl'h)₂ (Kekulé a. Szuch, C. R. 64, 752).—4. By the action of Na on SO(C, H₅), (Colby a. McLoughlin, Am. 9, 67) .- 5. By the action of NaSPh on C.H.N.Cl in molecular proportions (Ziegler, B. 23, 2471) .- 6. By heating benzene with S and AlCl, at 80° (Friedel a. Crafts, A. Ch. [6] 14, 438).

Preparation .- Ammonium sulphide is slowly adled to an acid solution of diazobenzene, cooled with ice, the oil which separates is cohobated for 2 or 3 hours to decompose the disulphide, and finally distilled; the yield is good (Grache a. Mann, B. 15, 1683).

Properties .- Oil, with slightly alliaceous odour, v. sol. hot alcohol, miscible with ether. Its alcoholic solution is not ppd. by AgNO, or HgCl. Yields di-phenyl-sulphone on oxidation.

Di-phenyl disulphide Ph.S. Mol. w. 218.

[61°]. (310).

Formation.—1. By oxidising phenyl mer-naptan with dilute HNO₃ (Vogt, A. 119, 142; Otto, A. 143, 213), with chromic acid mixture (Kekulé, Z. 1867, 194), and by exposure of its ammoniacal solution to air. -2. From NaSPh and CyCl (Clemm, J. pr. [2] 1, 147). -3. Together with mercury by distilling Hg(Sl^hh)₂ (Dreher a. Otto, A. 154, 178).—4. From NaSl^h and I (Hübner a. Alsberg, A. 156, 330).—5. In small quantity by adding zinc-dust to a mixture of S.Cl., and benzene (Schmidt, B. 11, 1173) .- 6.

solution of phenyl-hydrazine in benzene, and heating to boiling (Michaelis a. Ruhl, B. 23,

Properties .- Needles, with faint odour, insol. water, v. sol. alcohol and ether.

Reactions. -1. Reduced by zinc and dilute H.SO, to C.H.SH.-2. Oxidised by nitric acid to benzene sulphonic acid .- 3. Split up by long boiling into Ph.S and S (Graebe, A. 174, 189). 4 Alcoholic potash forms KSPh and C.H.SO.K. 5. Alcoholic K.S forms KSPh.-6. Bromine forms crystalline Ph.SBr.

Di-phenyl tetra-sulphide (C₆H₃)₂S₄. S.G. 145 1-297. Formed by the action of H₂S on a conc. alcoholic solution of benzene sulphinic acid (Otto, J. pr. [2] 37, 208). Formed also by the action of S₂Cl₂ on phenyl mercaptan. Thick yellow oil, m. sol. alcohol, v. sol. ether,

Di-phenyl hexasulphide (CaH,),S amorphous solid formed by heating benzene (20 g.) with S.Cl. (10 g.) and iodine (1 g.) for 100 hours at 120° (Onufrovitch, B. 23, 3368).

References .-- AMIDO-, AMIDO-IMIDO-, BROMO-, CHLORO-, CHLORO-NITRO-, IODO-, NITRO-, and OXY-DI-PHENYL SCLPHIDES. V. also DI-PHENYL-DI-PHENYL SULPHIDE.

DI-PHENYL SULPHIDE o-CARBOXYLIC ACID Calla. S.CaHa. COaH. Formed by the action of alkalis on the product of the action of NaSPh on diazotised o-amido-benzoic acid (Ziegler, B. 23, 2471). Plates (from benzene), insol. water.

PHENYL SULPHINIC ACID is BENZENE SHEDWING ACTO.

Diphenyl sulphinic acid CaH.Ph.SO.H. Got by reducing C12H2.SO.Cl in ether with sodiumamalgam (Gabriel a. Deutsch, B. 13, 388). Crys talline powder, decomposing at about 70%.

PHENYL SULPHITE (Schall, B. 25, 1490, 1875). The salt NaSO, OPh is formed from NaOPh and SO, and exhibits the following reactions :- 1. Alkyl i dides convert it into phenyl ethers of the sulphonic acids R.SO, OH. 2. Benzyl ether forms phenyl benzyl oxide, SO., and NaCl at 180° (yield 16 p.c.).—3, COCl. forms CO(OPh)., SO₂, and NaCl at 180°.—4. Ioloform (1 mol.) heated with NaSO.OPh (3 mols.) at 180° forms MeI, CH₃.SO₂.OPh, and 'rubbadin.' Rubbadin C₄₄H₃₂S₄O₃, mol. w. 830 (by Racult's

Inethod, calc. 806). Rub. crystallises from dilute alcohol in minute brownish-red plates, S. (alcohol) 43 at 20°, and forms a claret-coloured solution in alkalis. Its solution in NH, Aq dyes silk and wool pale-claret colour, and cotton yellowish-violet.

Reactions .- 1. Reduced by zinc dust and NaOHAq to C₄₄H₃₄S₃O₅.—2. Conc. HNO₃, free from nitrous fumes, at 0° forms C₄₄H₃₆(NO₂),S₃O₆, a red crystalline powder, m. sol. hot alcohol, which may be reduced to C₁₄H_{2.}(NO₂)₁(NH₂)₂S₂O₆, a glittering black crystalline powder (from ethera glittering black crystalline powder (from etherphenol) which yields a black crystalline di-acetyl
derivative.—3. HClAq at 200° forms phenol
(2 mols.), H.S (2 mols.), and C₂H₂₀S₂O₈, a
reddish-brown crystalline powder which yields
the derivatives C₂H₁₈Ac₂S₂O₈, C₂H₁₈Mc₂S₂O₈,
and C₂H₁₈Pr₄Ac₈S₂O₈.—4. Fusion with NaOH
forms SO(C₂H₄OH)₂ [96°] and salicylic acid.

Di-acetyl derivative C₄H₂₈Ac₈S₂O₈.

Der brown powder decouppessed by heat with.

Dark brown powder, decomposed by heat without previous fusion. Split up by long boiling with alcohol into O_mH_aS₁O_p, sol. alcohol

and C₂₁H₂₂S₂O₄, insol. alcohol. Br in chloro-form converts the di-acetyl derivative into C₄₄H₂₁Br₄Ac₃S₄O₅. Di-methyl-rubbadin C₄₄H₃₀Me₂S₄O₄. Got from rubbadin, KOHAq, and MeI. Dark reddish-

brown powder.

SULPHOCYANIDE C.H. SCN. PHÈNYL (231° cor.). S.G. 17.5 1.155. Formed from Pb(SPh)2 and CvCl. Prepared by adding cuprous sulphocyanide to a solution of diazobenzene sulphate and potassium sulphocyanide (Billeter, B. 7, 1753; Gattermann & Haussknecht, B. 23, 738). Liquid. Yields phenyl mercaptan when heated with alcoholic potash.

[97°]. Got from Polymeride (Ph.SCy)_s. [97°]. Got from PhSNa and cyanuric chloride (Klason, J. pr. [2]

33, 120). Prisms (from HOAc).

Reference. -- NITRO-PHENYL SULPHOCYANIDE.
PHENYL SULPHOCYANO-ETHYL KETONE C₁₀H₂NSO i.e. C₆H₅.CO.C₂H₄.SCy. Get from C.H. CO.C.H.Br and KSCr in alcohol (Pampel a. Schmidt, B. 19, 2897). Liquid.

DI-PHENYL BULPHONE (C, H,)2SO2 Sulphobenzide. Mol. w. 218. [1286]. (376°) at

722 mm.

Formation. — 1. From benzene and SO, (Mitscherlich, P. 31, 628; Freund, A. 120, 76; Otto, A. 136, 160), furning H.SO, (Berthelot, B. 9, 349), or HSO Cl (Knapp. Z. (2) 5, 41). - 2. By oxidation of Ph.S (Stenhouse, A. 140, 290; Kekulė a. Szuch, Bl. (2) 8, 204). - 3. By distilling benzene sulphonic acid (F.). - 4. From benzene, C.H.SO,Cl, and AlCl; the yield being 80 p.c. of the theoretical amount (Beckurts a. Otto, B. 11, 2066).—5. By heating benzene (200 c.c.) with conc. H2SO4 (300 c.c.), the yield being 6 p.c. of the benzene employed (Istrati, Bl. [3] 1, 492) .-6. By heating C. H. SO. Cl with HgPh, (Otto, B. 18, 248) .- 7. By oxidation of di-phenyl sulphoxide with KMnO, and HOAc (Colby a. McLoughlin, Am. 9, 67).

Properties .- Monoclinic prisms (from benzene) or plates (from alcohol), y. sol, ether. PCl, at 160° forms C₄H₃SO₂Cl and chloro-benzene. Converted by potash-fusion into phenol, diphenyl, Ph.S. PhSII, and other boules (Otto, B. 19, 2425). Hot fuming H.SO, forms benzene sul-

phonic acid.

Вкомо-, Ситоко-, References. - AMIDO-, NITRO-, OXY-AMIDO-, and OXY- DI-PHENYL SUL-

PHENYL SULPHONE ACETIC ACID v. PHENYL-SULPHONO-ACETIC ACID.

DI-PHENYL SULPHONE o-CARBOXYLIC ACID C₁₁H₁₀SO₄ i.e. C₀H₁,SO₂C₀H₁,CO₂H₂ [152°]. Formed by oxidising PhS.C₀H₁,CO₂H with 11NO₄ (Graebe a. Schultess, A. 263, 7). Needles (con-'aining aq). Melts at 99° when hydrated.

Di-phenyl sulphone p-carboxylic acid. [above 300°]. Got by oxidation of phenyl tolyl sulphone with KMnO, (Michael a. Adair, B. 11, 119). Prisms (from alcohol), sl. sol. hot water. - AgA'.

Di-phenyl sulphone di-carboxylic acid SO₂(C₂H₂,CO₂H₃)₂. [above 300°]. Got by oxidising di-p-tolyl sulphone (M. a. A.). Small prisms, sol. nitrobenzene.

DI-PHENYL SULPHONE m-SULPHONIC ACID C.H., SO. C.H., SO.H. Got by heating diphenyl sulphone (1 mol.) with HO.SO₂Cl (1 mol.) at 450° (Otto, B. 11, 2075; 19, 2417). Fibrous orystalline mass, v. sol. water. - KA'aq.

PHENYL-SULPHONO-ACETIC ACID C_uH₂SO₄ i.e. C_uH₃.SO₂.CH₂.CO₂H. [112°].

Formation. -1. From sodium benzene sulphinate and chloro-acetic acid (Gabriel, R. 14. 834) .- 2. By saponifying its ether which is got by boiling sodium benzene sulphinate with chloro-aceto-acetic ether (Otto a. Rössing, B. 23, 755).-3. By oxidising phenyl-thio-glycollic acid (Claesson; Blomstrand, B. 4, 712; 8, 120; Otto, B. 19, 3138).-4. By warming phenyl oxyethyl sulphone (1 vol.) with H₂SO₄ (1 vol.) diluted with water (2 vols.), and extracting with ether (Otto, J. pr. [2] 30, 340).

Properties.—Monoclinic crystals, m. sol. water, but separated by addition of NaCl. Sol. alcohol and ether.

Reactions.-1. Reduced by sodium amalgam to benzene sulphinic and acetic acids.-2. Gives off CO₂ above 160°, forming phenyl methyl sulphone.—3. Chlorine, passed into its warm aqueous solution, forms CHCl₂SO₂C₄H, [59°].—4. PCl₂ gives the chloride [58°], and at 110° forms C₆H₃SO₂CCl₂COCl, which on treatment with water gives C₄H₃SO₂CHCl₂ (Otto, J. pr. [2] 40, 540).

Salts.—BaA', 2aq.—CuA', 2aq.—CaA', 21aq. -PbA', 2aq.—AgA'. Sparingly soluble needles.

Methyl ether MeA'. Oil (Otto, J. pr. [2] 86, 436).

saponified by NaOHAq, while KOHAq gives phenyl methyl sulphone. Bromine at 90°, followed by NaOHAq, forms C_hH_sSO_xCHBr_s [76°]. Alcoholic potash forms Ph.SO_xMe (Michael a. Milner, Am. 7, 65). NaOEt forms the compound C_nH.,SO, CHNa.CO,Et, which yields Ph₂S₂, Ph₂S, PhSEt, and Ph.SO,Me on distillation (Otto a.

Rossing, B. 22, 1455; 23, 1647).

Chloride Ph.SO, CH, COOI! [58°]. Needles (trom water). Yields Hg(C,H,NSO,), [215°] on boiling with HgO.

PHENYL-SULPHONO-ACETONE v. PHRNYL METHYLENE METHYL SULPRONE-METONE.

Di-phenyl-di-sulphono-acetone v. DI-PHENYL DI-METHYLENE DISULPHONE-KETONE

PHENYL-SULPHONO-ANGELIC ETHER

C,H,SO, i.e. C,H,SO,CH(C,H,SO)Et. [64:5°]. Got from PhSO,CINA.CO,Et and allyl iodid: (Michael, Am. 7, 67). Prisms (from alcohol). PHENYL-SULPHONO-n-BUTYRIC

C.H.SO.CHELCO.H. [124°]. Formed from benzene sulphinic acid, a-bromo-butyric acid, and Na₂CO₃Aq (Otto, B. 21, 996). Needles, m. sol. water. Yields phenyl propyl sulphone on heating.

Di-phenyl-di-sulphono-butyric ether

(C.H., SO.), CMe.CH., CO.Et. [97°]. Got by oxidation of (PhS), CMe.CH., CO.Et (Autenrieth, A. 259, 367). Small crystals, insol. water. Converted by KOHAq into benzene sulphinic acid and B-plienyl-isocrotonic acid.

PHENYL-SULPHONO-CROTONIC ACID

C.H., SO. CMc:CH.CO.11. [158]. S. ½ 38; 122 25. Formed by heating the Na salt of β-chloro-crotonic acid [94·5°] with sodium henzene sulphinate in aqueous solution at 170° (Autenrieth, A. 259, 343). Plates (from water), m. sol. ether. At 210° it slowly changes to the following isomeride [127°]. -KA' 1 aq. - BaA' aq. - MgA'₂ 7aq. - ZnA'₂ 6aq. - CuA'₂ aq. - AgA'. [200°]. Matted needles (from water).

Phenyl-sulphono-isocrotonic acid C.H., SO, CMe: CH.CO.H. [127°]. S. 26 at 15°; 5 at 150°. Formed by heating β -chloro-isocrotonic acid with sodium benzene sulphinate in aqueous solution at 145°. Got also by saponifying di-phenyl-di-sulphono-isobutyric ether (Autenrieth, A. 259, 335). Feathery needles. Yields benzene sulphinic acid [81°] on boiling with Dotash.— KA' 3aq.—BaA', 2½aq.— MgA', 6aq.— ZnA', 6aq. [120°] (hydrated).—AgA'. [c. 243°]. Ethyl ether EtA'. Oil.

DI-PHENYL-DI-SULPHONO-DI-ETHYL OXIDE C₁₆H₁₈S₁O₃ i.e. O(C.H₁SO₂Ph)₂. [70°]. Formed from C₃H₃SO₂C₂H₃Cl and dry Ag₂O (Otto, J. 27. [2] 30, 202). Needles, sol. benzeno. A polymeride [88°] is got by heating the compand (O.H. SO) C.H. with KOHAG. pound (CoH.SO2)2C2H, with KOHAq.

DI-PHENYL-DI-SULPHONO-DI-ETHYL SULPHIDE S(C,H,SO,Ph), [124°]. Got from C,H,SO,C,H,Cl and alcoholic KSH (Otto, J. pr. [2] 80, 348). Needles (from dilute alcohol).

DI - PHENYL - DI - SULPHONO - HEXOIC ETHER (C.H., SO.), CMe. CHEŁ. CO.Et. [111°]. Got by oxidising (PhS), CMe. CHEŁ. CO.Et (Autenrieth, A. 259, 372) Crystals, v. sol. alcohol.

DI. PHENYL . DI . SULPHONO . DI . PHENYL OXIDE (C.H., SO., C.H.), O. [70°]. (above 200°). Got by heating C.H.(SO.Ph), with alcoholic potash at 165° (Otto a. Rössing, B. 20, 187). Needles, v. e. sol. alcohol, insol. water.

PHENYL-a-SULPHONO-PROPIONIC ACID C₆H₃,SO₂,CHMe,CO₂H. [116°]. Formed by heating a-bromo-propionic ether with sodium benzene sulphinate and ether. Minute needles. -NaA'.-BaA', 2aq.-EtA'. [c. 17°

Phenyl. B. sulphono. propionic acid ChH., SO., CH., CO., H. [124°]. Got from B-bromo-propionic acid, benzene sulphinic acid. and Na₂CO₃Aq (Otto, B. 21, 89). Plates, sl. sol.

cold water. DI-PHENYL SULPHOXIDE (C₄H₃)₂SO. [71°]. Formed by the action of SO₂ or SOCl₂ on benzene in presence of AlCl₃ (Colby a. McLoughlin, Am. 9, 67; B. 20, 195). Triclinic McLoughlin, Am. 9, 67; B. 20, 195). Triclinia crystals, v. sol. alcohol. Oxidised by KMnO, to Ph.SO.. Reduced by sodium to Ph.S. NaNO, and II.SO, give SO(C₆H₄.NO₂)₂ [116°] and SO₂(C₆H₄.NO₂)₂ [163°].

Di-phenyl-di-sulphoxide v. Phenyl ether of

BENZENE THIOSULPHONIC ACID.

PHENYL-SULPHURIC ACID v. PHENYL SULPHATE and PHENOL. Reaction 19.

PHENYL SULPHUROUS ACID v. BENZENE SULPHONIC ACID.

PHENYL SULPHYDRATE v. PHENYL MER-CAPTAN.

PHENYL-SULPHYDRO-ACETIC ACID v. PHENYL-THIOGLYCOLLIC ACID.

PHENYL - SULPHYDRO - ACETOPHENONE C_sH_s.CO.CH_x.SPh. [53°]. Formed from ω-bromo-acetophenone and NaSPh (Delisle, B. 22, 306).

Crystals, v. sol. ether and acetone.
DI - PHENYL - DI - SULPHYDRO - BUTYRIC ETHER C, M, S, O, i.e. (PhS), CMe.CH, CO, Et. [58°]. Got by passing HCl into a mixture of acctoacetic ether and plienyl mercaptan (Escales a. Baumann, B. 19, 1790). Pearly plates (from alcohol), v. sol, ether.

PHENYL-SULPHYDRO-CROTONIC CH3.CH:C(SPh).CO2H. [86°]. Formed by the action of Na and phenyl mercaptan on the Na salt of a-chloro-crotonic acid [97°] (Antenrieth, A. 254, 246). Needles or plates. Its K salt is

hygroscopic, S. (alcohol) 20 8.

Isomeride CHMe:C(SPh).CO.H. [80°]. Got in like manner from the stereo-isomeric liquid chloro-crotonic acid. White plates. Its K salt is hygroscopic, S. (alcohol) 10.4.

Phenyl-B-sulphydro-crotonic acid

CH₄.C(SPh):CH.CO₂H or CH₂:C(SPh).CH₂.CO₂H. [177°]. S. (alcohol) 2 in the cold. Formed, together with small quantities of an isomeride [145°], by warming di-phonyl-di-sulphydrobutyric ether with alcoholic soda (Escales a. Baumann, B. 19, 1791). Plates (from alcohol), insol. water.—BaA', 2aq.—AgA', amorphous pp.

Isomeride CH, C(SPh):CH.CO₂H. [158°].

Formed from phenyl mercaptan and the Na salt of chloro-crotonic acid [95°] (Autenrieth, A. 254, 230). Both acids form a chorry-red solution in H.SO

DI-PHENYL SULPHYDRO-ETHYLIDENE DISTLIPHONE. Phenyl derivative (C.H.,SO.),CMe.SPh. [194°]. Got by heating (C.H.,SO.),CH.SPh with alcoholic soda and MeI at 1006 (Laves, B. 23, 1416). Crystals (from | chloroform)

DI - PHENYL - DI - SULPHYDRO - HEXOIC ETHER CH₂.C(SPh)₂.CHEt.CO.Et. [71°]. Got from ethyl-acetoacetic ether, phenyl mercaptan, and HCl (Autenrieth, A. 259, 371). Shining crystals, v. sol. ether and alcohol.

DI-PHENYL SULPHYDRO-METHENYL DI-

SULPHONE. Phenyl derivative (C.H.SO.), CH.SPh. [175°]. Got by the action of KMO, and dilute H.SO, on CH(SPh), dissolved in benzene (Laves, B. 23, 1414). Silky needles, m. sol. chloroform, nearly insol. water and alcohol, sol. alcoholic NaOH. May be oxidised to CH(SO,Ph), [215°].
DI-PHENYL-DI-SULPHYDRO-PHENYL-

ACETIC ACID C.H. C(SPh)...CO.H. Formed from phenyl-glyoxylic acid, phenyl-mercaptan, and HCl (Escales a. Baumann, B. 19, 1789). Insol. water, v. sol. ether. Crystallises from benzene with \(\frac{1}{2}C_{\text{H}_0}^{\text{H}_0} - \text{KA'} 1\)\)aq. \(\text{PHENYL - SULPHYDRO - PHENYL - THIO-} \)

 $\stackrel{N\mathrm{Ph.N}}{CS-S}\!\!\searrow\!\!C.\mathrm{NH.NHPh.}$ BIAZYL-HYDRAZINE

[142°]. Got by reducing the corresponding azocompound with alcoholic ammonium sulphide (Freund a. Kuh, B. 23, 2830). Plates, sl. sol.

DI-PHENYL - DI - SULPHYDRO - PROPIONIC ACID CH3.C(SPh) CO.H. [117°]. Got from pyruvic acid, phenyl mercaptan, and RCl (Escales a. Baumann, B. 19, 1787). Needles (from ligroin). - NaA'. BaA', 2aq : v. sol. hot Aq. Amide. [93°]. Needles (from alcohol). DI-PHENYL SULPHYDRO-PROPYLENE

Phenyl derivative DISULPHONE. C.H., SO, CH., CMe(SPh), SO, C.H., [149°]. Formed by oxidising C.H., SO, CH., CMe(SPh), with KMnO, in the cold (Otto a. Rossing, B. 21, 234). Crystalline granules, sl. sol. cold alcelol.

DI-PHENYL-DI-SULPHYDRO-VALERIC ACID CH, C(SPh), CH, CO,H. [69°]. Got from phenyl mercaptan, 8-acetyl-propionic acid and HCl (Escales as Baumann, B. 19, 1795). Prisms (from chloroform-ether).—BaA'...

PHENYL-TETRIC ACID C₁₁H₁₀O₂

CH2Ph.CH.CO CO.CH. >0. Formed by heating bromo-

benzylacetoacetic ether (Moscheles, B. 21, 2608). Not affected by HClAq at 170°. Yields a benzoyl derivative CuH, BzO, [110°] crystallising in needles.

PHENYL-THIAZOLE C,H,NS i.e.

N CH .S [52°]. (273° cor.). Got by the diazo- reaction from the amido-phenyl-thiazole that is produced by the action of thio-urea on bromo-acetophenone (Popp, A. 250, 279; cf. Arapides, A. 249, 25). Sl. sol. cold water.— "B'HCl. [80°]. Needles.—B',H,PtCl, 2aq. [196°]. -*B'HHgCl₂. [155°].-Picrate. [165°]. *B'HAuCl₄. [175°]. Needles (from alcohol).

N≪CH :CH. μ -Phenyl-thiazole Formed by heating thio-benzamide with edichloro-di-ethyl oxide at 100°. Oil.-B'HCl 2aq.

chloro-di-ethyl oxide at 100°. Oil.—B'HG zaq. [62°].—B'H.PtCl.2aq. [175°] (when anhydrous).
—Picrate. [125°]. Yellow needles.

Dibydride N CPh.S.
CH., CH. Phenyl-thiasoline. (276). Got by heating thio-bensamide

with ethylene bromide (Gabriel a. Heymann, B. 23, 158; 24, 784). Formed also by the action of PCl₂ on S₂(C₂H₂NHBz)₂ (Gabriel a. Coblent#, B. 24, 1124). Oil. Yields a crystalline dibromide. — B'₂3HCl₂ — B'C₂H₂N₃O₃. [172°]. Yellow needles .-- B' H. PtCl.

v-Phenyl-thiazole. Tetra-hydride

NPh CH.S. Got by reducing ethylene phenyl-di-thio-carbamate [128°] with tin and HCl (Fönster, B. 21, 1871). Oil. B', H. PtCl.

Di-phenyl-thiazole N CPh.S CPh.CH [93°]. (above 360°). Got from thiobenzamide and bromo-acetophenone in alcohol (Hubacher, A. 259, 237). Plates, v. sol. alcohol and ether.

Tri-phenyl-thiazole NCPh.S Got from thiobenzamide and bromo-deoxybenzoïn (Hubacher, A. 259, 245). Prisms (from ether), in. sol. alcohol, nearly insol. HClAq.

Reference.—Oxy-PHENYL-WHAZOLE.

PHENYL-DITHIENYL C.H.S.C.H.PhS. [209]. A product of the action of \hat{S} on toluene at a real heat (Renard, C, R, 111, 48). Plates, v. sl. sol, alcohol and ether. Gives a blue colour with isatin and H2SO4, and a green colour with phenanthraquinone and H_2SO_4 . Gives rise to $C_{14}H_1Br_8S_2$ [320] and $C_{14}H_8(NO_2)_2S_2$ [273°].

PHENYL THIENYL KETONE v. THIENYL' PHENYL KETONE.

(α)-PHENYL-(β)-THIO-ALLOPHANIC ACID

Ethyl ether. C₁₀H_{1,}N₁SO₂ i.e. NH₂CS.NPh.CO₂Et. [127°], Formed from NHAc.CS.NHPh and ClCO₂Et (Seidel, J. pr. [2] 32, 275). Monoclinic tablets, converted by alcoholic NH, at 100° into phenyl-thio-urea.

(B)-Phenyl-thio-al'ophanic acid. ether NHPh.CS.NH.CO.Et. Got from phenylthio-urea and ClCO₂Et (Seidel, J. pr. [2] 32, 270). Oil. AcCl at 60° forms NHAc.CS.NHPh [170°].

Phenyl di-thio-allophanic acid. Isoamyl ${\rm NHPh.CS.NH.CO.SC.H_{H}}.$ ether [102°]. Formed from phenyl-thio-urea and Cl.CO.SC, H₁₁ (Schöne, J. pr. [2] 32, 256). Needles. Very unstable. Forms an acetyl derivative [246

Di-phenyl-thio-allophanic acid. Ethyl ether NHPh.CS.NPh.CO.Et. [95°]. Formed from di-phenyl-thio-ures and ClCO,Et (Seidel,

J. pr. [2] 32, 262). Prisms (from alcohol). Alcoholic AgNO₃ ppts. C₁₆H₁₆N₂SO₂AgNO₃. Reactions.—1. Caustic potash regenerates CS(NHPh).—2. Aqueous ammonia at 100° forms NHPh.CS.NH₂ and NHPh.CO₂Et. — 3. Alcoholic aniline at 100° forms CS(NHPh)₂ and NHPh.CO₃Et. — 3. NHPh.CO,Et .- 4. HgO in presence of alcoholic ammonia forms (NHPh.CO.NPh.CO.Et), HgO [129°], a crystalline body that is reconverted by H2S into di-phenyl-thio-allophanic ether .- 5. By heating in a current of HCl it is converted into CS(NHPh)2, aniline, and phenyl-thiocarbimide.

Di-phenyl-di-thio-allophanic acid. amyl ether NPhH.CS.NPh.CO.SC.H ... [87°] Got from di-phenyl-thiures and Cl.CO.SC, H, (Schöne, J. pr. [2] 32, 258). Needles (from alcohol). It is insoluble in cold water, but decomposed by hot water. Its alcoholic solution is ppd. by AgNO, HgCl, or PtCl. HgO and NH, convert it (in alcoholic solution) into di-phenyl- | Formed also by the action of alcoholic potash guanidine, [147°].
TRI-PHENYL-THIO-AMMELINE

 C_nH_1,N_sS i.e. $C(SH) \leqslant N - C(NPh) > NH$. [238°]. Formed from phenyl-cyanamide and phenylthiocarbimide, and got also by heating tri-phenylbiguanide with CS, at 100°, and by heating diphenyl-guanidine with phenyl-thiocarbimide, alcohol, and mercury sulphocyanide (Rathke, B. 20, 1065; 23, 1673). Plates (from chloroform). Converted by alcoholic potash into tri-phenylammeline. Alcohol and EtBr at 100° form C₁H₁,EtN₂SHBr, crystallising from alcohol in plates.—B'HCl.—AgC,HPh₂N₂S: yollow pp. DI-PHENYL-THIO-BENZAMIDE

Ph.CS.NPh₂. Formed by heating di-phen, l-benzamidine with H₂S or CS₂ at 130° (Bernthsen, A. 192, 38). Yellow triclinic crystals (from benzene); a:b:c = .927:1: .766, $\alpha = .93^{\circ} \cdot .29^{\circ}$, $\beta =$ 100° 55', $\gamma = 84^{\circ}$ 14'. Insol. ccld water, sl. sol. cold alcohol.

PHENYL-DI-THIO-BIURET C₈H₉N₉S₂ i.e. IPh.CS.NH.CS.NH₂. [174°]. Formed by NHPh.CS.NH.CS.NH,. heating aniline with perthiocyanic acid (Glutz, A. 154, 44). Got also by boiling carbinidophonyl-thio-urea with ammonium sulphide (Wunderlich, B. 19, 452). Prepared by adding phenyl-thiocarbimide (36 g.) to an alcoholic solution of cyanamide (11 g.) and Na (6 g.), and decomposing the pp. by dissolving in a solution of NH₄Cl (14.5 g.) containing NH₃Aq (50 c.e.), passing in H₂S, and heating to boiling (Hecht,

B. 25, 756). Pearly plates, sl. sol. hot water.—B'HCl.—B'HNO. Ethyl derivative C.H.Eth.S ..

Got by adding alcohol, NH, Aq, and Et to the base (Tursini, B. 17, 584). Trimetric tables. PHENYL-THIO-CARBAMIC ACID

NHPh.CO.SH. Methyl ether NHPh.CO.SMe. [84°]. Formed by heating di-phenyl-methyl-4thio-urea NHPh.C(NPh).SMc with dilute H.SO. (Will, B. 15, 339). Plates, sol. alcohol, ether, and benzene. Decomposed by KOH into aniline, MeSH, and CO. Boiling alcoholic NH, forms MeSH and phenyl-urea. Aniline gives methyl

with dilute H2SO, and by the action of aniline on Cl.CO.SEt (Will).

Isoamyl ether NHPh.CO.SC,H₁₁. [67°]. Got from aniline and Cl.CO.SC,H₁₁. (Schöne, J. pr. [2] 32, 249). Needles (from ether).

Got by heating di-phenyl-ethylene-v-thio-urea with dilute HClAq at 200° (W.). Formed also by the action of chloro-acetic acid on the ethylene ether of phenyl-di-thio-carbamic acid (Evers, B. 21, 976). Needles, sol. alcohol and ether, insol. acids and alkalis.

Phenyl other NHPh.CO.SPh. [125°]. Formed by heating phenyl mercaptan with phenyl cyanate (Snape, C. J. 47, 778; B. 18, 2432). Needles, v. sol. alcohol and ether.

Phenyl-v-thio-carbamic acid NHPh.CS.OH. Ethyl ether C.H., NSO i.e. NHPh.CS.OEt or NPh:C(SH).OEt. [72°]. Formed by heating phenyl-thiocarbimide with alcohol (Hofmann, B. 2. 120; 8, 772; Bamberger, B. 15, 2164).

on phenyl-thiocarbimide (R. Schiff, B. 9, 1316). Triclinic prisms, sol. alkalis and reppd. by CO, Resolved by distillation into alcohol and phenylthiocarbimide. Oxidised by alkaline K₂FeCy₅ to C₁₈H₂₀N₂O₂S₂ or S₂(C(NPh).OEt)₂ [102°], which is also got by the action of I on C.H. NOSAg (Liebermann a. Natanson, B. 13, 1575; Jacob-(Liebermann a. Natanson, B. 13, 1075; Jacobsen, B. 19, 1076).—(C₂H₁₀NO.S)₂Pb 2aq: small needles.— C₂H₁₀NOSAg.— C₂H₁₀NOSHgClHCl: needles.—(C₂H₁₀NOS).Hg. [78°] (Stephanovitch, B. 7, 692).—(C₂H₁₀NOS).HgAgNO₂. Needles.—(C₂H₁₀NOSMc. [260°-265°). Oil.—C₂H₁₀NOSEd. [30°]. (275°). Prisms; decomposed by dilute H.SO, at 200° into aniline and CO(OEt)(SEt) (Liebermann, B. 13, 682; A. 207, 148). -C_oH₁₀NOSC₁H₉. [75°] (Mylius, B. 5, 977). Phenyl ether NHPh.CS.OPh. Got by Got by

heating phenyl-thiocarbimide with phenol at 145° (Dixon, C. J. 57, 268). Sulphur-yellow octahedra; decomposed by heat.

Phenyl di-thio-carbamic acid NHPh.CS.SH. Splits up into CS, and aniline when set free from its salts.

Salts .- The salt NHPh.CS.SK is formed by boiling potassium xanthate EtO.CS.SK (1 mol.) with an alcoholic solution of aniline (1 mol.) (Rathke, B. 11, 958). Prepared from CS, aniline, ether, and alcoholic potash (Losanitsch, B. 24, 3024). Yellow monoclinic needles, v. c. sol. water and alcohol, insol. ether. Yields CS(NHPh), when heated. Boiling water forms phenyl-thio-carbimide and CS(NHPh),.—NHPh.CS.SNH,. Yellow prisms. Converted by I into (NIIPh.CS), S [138°]. BaA'₂: yellowish plates. - NiA'₂.

Methyl ether NHPh.CS.SMe. [93.5°].

Formed from the NH, salt and MeI (L.) and also by heating NHPh.C(NPh). SMe with CS, at 160° (Will, B. 15, 342). Decomposed by alkalis into MeSH and aniline.

Ethylether NY Ph.CS.SEt. [60°]. Formed from phenyl-thiocarbimide and mercaptan at 150° (Hofmann, B. 2, 120; Will, B. 15, 1305), and also by the action of EtI on the ammonium salt (L.). Tables, v. sol. alcohol, sol. alkalis.

Isoamyl ether C.H., A'. [171°].

Ethylene, derivative CS NPh.CH, [634°]. Formed, together with phenyl-thiocarbimide, by heating C(NPh) < NPh. CH2 with CS2 at 200° (W.). Needles. Converted by MeI into C,H,NS,McI [149°].

References .- Bromo-, Chloro-, and Nitro-PHENYL-THIO-CARBAMIC ACID

PHENYL-THIOCARBAMINE-CYAMIDE v. CARBIMIDO-PHENYL-THIO-UREA

PHENYL - THIOCARBAMINE - ETHYL . CYAMIDE v. ETHYL-CARBINIDO-PHENYL-THIO-

PHENYL-THIO-CARBAZIC ACID
NHPh.NH.CO.SH. The phenyl hydrazine salt
NHPh.NH.CO.SN.H.Ph [84°] is formed from phenyl-hydrazine and COS (Heller, A. 263, 269). . Phenyl di-thio-carbasic acid

NHPh.NH.CS.SH. Formed, as phenyl-hydrazine salt NHPh.NH.CS.SN.H.Ph [97°] by adding CS. to an ethereal solution of phenyl-hydrazine (Fischer, A. 190, 114). Plates, ev. sol. alcohol and ether. Readily decomposed by Leat into CS(N,H,Ph), CS, H,S, and NH,

PHENYL-THIO-SEMICARBAZIDE C.H.N.S i.e. NH, OS.NH.NHPh. [201°] (F.; P.); [190°] (S. a. R.).

Formation .- 1. By warming di-phenyl-thiocarbazide with alcoholic or aqueous alkalis (Fischer, A. 212, 324).—2. By heating phenylhydrazine sulphocyanide. - 3. By heating phenylhydrazine with thio-urea or with phenyl-thiourea (Pellizzari, G. 16, 203; Skinner a. Ruhemann, C. J. 53, 550; B. 20, 3373).

Properties.-Needles, insol. ether, sl. sol. hot water, v. sol. hot alcohol. Conc. HClAq at 120° forms phenyl-thiocarbiane C.H., N.S. COCl. forms CO:N., Ph.CS.NH₂ [c. 270°] crystallising from HOAc (Freund, A. 21, 2465).

Acetyl derivative NHPh.NH.CS.NHAc. [179°]. Formed by mixing solutions of acetylthiocarbimide and phenyl-hydrazine in dry benzene (Dixon, C. J. 55, 303). Small prisms.

Benzoyl derivative C₁H₁₃N₃SO. Silky needles. Does not melt at 220°.

CS(NH.NHPh)2 Di-phenyl-thiocarbazide [c. 150°]. Formed by heating the compound of phenyl-hydrazine and CS, at 110°-140° (Fischer). Formed also from phenyl-hydrazine and CSCl., (Heller, A. 263, 278). Triangular prisms (from alcohol). Dissolves in hot aniline, forming a solution which is green in thin layers, but red in thick layers. Hot alcoholic potash also forms this dichroic substance, di-phenyl-thiocarbazone C₁₃H₁₂N₄S).ZnO, and may be reduced by zinc-dust and NaOHAq to phenyl-thio-semicarbazide and aniline. Di-phenyl-thio-carbazone may be oxidised by ppd. MnO, in presence of alcoholic potash to red needles of di-phenylthiocarbodiazone CS(N.Ph)...

Di-phenyl-thio-semicarbazide NIIPh.NH.CS.NIIPh. [177]. Formed from phenyl-hydrazine and phenyl-thiocarbimide in alcoholic solution (Fisc. ct. A. 190, 122). Prisms (from alcohol), sl. sol. ether. COCl, forms CO:N,Ph.CS.NHPh [188°], crystallising in needles (Kreund, B. 21, 2466).

Butyryl derivative

C.H,O.NPh.NH.CS.NHPh. [156°]. Formed from sodium phenyl-hydrazine, phenyl thiocarbimide, and n-butyryl chloride (Michaelis a. Schmidt, A. 252, 309). V. sol. hot alcohol.

Benzoyl derivative

NPhBz.NH.CS.NHPh. [310°]. Obtained from NPhBz.NH, and phenyl-thiocarbimide (M. a. S.). Reference. - NITRO-DI-PHENYL-THIO-SEMICARB-

AZIDE. DI - PHENYL - THIO - SEMICARBAZIDE

CARBOXYLIC ACID C, H, N, O, S i.e. NHPh.CS.NH.NHC, H, CO, H. [204°]. Formed by warming m-hydrazido-benzoic acid with phenyl thiocarbimide and HOAc (Roder, A. 236,

Colourless needles.

PHENYL THIOCARBIMIDE C,H,NS i.e. C,H,N.OS. Mol. w. 135. (220°) at 750 mm. (Schiff, B. 19, 568). S.G. 1 1059 (Nasini a. Scala, G. 17, 66). S.V. 1434 (Schiff; Lossen. A. 254, 73).

Fornation.—1. By distilling phenyl-thioures with P.O. (Hofmann, Pr. 9, 274, 487; C. J. 18, 309; B. 15, 980).—2. By heating di-phenyl-thioures with conc. HClAq at 165° (Merz a. Waith, Z. 1869, 589).—3. By the action of I on a bensene solution of tri-phenyl-guanidine (Hof-

mann, B. 2.453; Rudneff, J. R. 10, 184).-4. By heating phenyl cyanate or phenyl-carbamic ether with P.S. at 160° (Michael a. Palmer, Am. 6, 258).—5. Formed, together with o- or p- tolyl-thiocarbimide, by heating phenyl-o- or p- tolylcyanamide (C,H,N:C:NC,H,) with CS, at 180°-200° (Huhn, B. 19, 2409).

Properties. - Pungent oil, volatile with

Reactions. - 1. Alcohol at 100° forms MHPh.CS.OEt, while mercaptan gives rise to NHPh.CS.SEt. — 2. Alcoholic polash forms CS(NHPh)₂ and CO(NHPh)₂ — 8. Ammonia forms CS(NHPh)₁ (NH₂), and inciding gives CS(NHPh)₂ and other amines act in like manner. - 4. PEt, acts violently, and forms $C_{12}H_{20}NPS$, while PMe₃ forms oily $C_{10}H_{20}NPS$, which yields crystalline B'HCl. - 5. Chlorine passed into its solution in chloroform forms (PhNCS)₂Cl₂ [150°-160°]• and PhNCCl₂ (212°). The chloride (PhNCS)₂Cl₂is converted by H.S into CS(NHPh)₃. and by warm spirit into (PleNCS)2O, crystallising in yellow needles [118°] (Helmers, B. 20, 786). 6. Bromine in chloroform or HOAc forms red crystals of (PhNCSBr.), decomposed at 100° into pale-yellow plates (PhNCSBr), [190°] (Helmers; cf. Proskauer a. Sell, B. 9, 1262). -7. SO. forms C,II,NS,O, [180°-183°], crystallising from benzene, and converted by water at 100° into amido benzene p sulphonic acid, CO2, and H2S (Magatti, B. 11, 2267).—8. PCl, at 100° forms $C_v H_s NCCl_2$ and $C_v H_s < N > CCl (248°)$ (Hofmann, B. 12, 1126).-9. CISO3H forms C11H10N2S3 [151°], insol. water, and SO₃H.C₃H₄NOS aq, sol. water (Pawlewski, B. 22, 2200).—10. Reduced copper at 200° forms benzonitrile.—11. H.S forms phenyl-thio-urea.—12. Boiling water forms CS(NHPh),, CO., and H2S (Bamberger, B. 14, 2642). — 13. HOAc forms, on heating, CO(NHPh)₂, Ac₂O, H₂S, and CO₂; the di-phenylurea being further split up into aniline and CO, with formation of Ac₂O (Cain a. Cohen, C. J. 59, 327; cf. Gumpert, J. pr. [2] 32, 294).—14. Chloro-acctic acid and alcohol at 170° form PhN:C S.CH. [148°], which yields aniline, CO. and thioglycollic acid on boiling with water (Liebermann a. Voeltzkoff, B. 13, 276).— 15. Sodium malonic ether in presence of alcohol forms C14H16SNO4Na, whence acids liberate Gi,H.,SNO, or (CO_Et),CH.CS.NHPh [60°] (Michael, J. pr. [2] 35, 451).—16. Sodium cyanamide and alkyl iodides form cyano-phonylalkyl-thio-ureas (Hecht, B. 23, 1664). In this way the following compounds may be prepared: NHPh.CS.NMeCy [186°], NHPh.CS.NECy [144°], NHPh.CS.NCyC,H, [100°], crystallising in needles, NHPh.CS.NCyC,H, [108°], crystallising in needles, and NHPh.CS.NCy.CH,Ph [189°]. 17. Aldehyde ammonia forms C 2H, N, 8, 0, [148°], crystallising from alcohol in silvery needles (R. Schiff, B. 9, 567; G. 6, 244).—18, Benzamidna hydrochloride and dilute NaOHAq form CPh(NH).NH.CS.NHPh [125°] (Pinner, B. 22, 1609). Prisms.

References .- BROMO-, CHLORO-, IODO-, NITRO-, and Oxy- PHENYL-THIOCARDIMIDE.

PHENYL-THIOCARBIZINE C.H.N.S i.a. CS NH. [129°]. Formed by heating phenyl-

thio-semicarbazide (10 g.) with dilute (20 p.c.) HClAq (80 c.c.) for 12 hours at 130° (E. Fischer, A. 212, 326). Plates (from water), v. e. sol. alcohol. May be distilled. McI forms C, H, MeN, S Does not reduce Fehling's solution. HIAq at 200° forms aniline, H.S, CO2, and NH2. Aqueous NaOCl forms a violet pp. which dissolves in H2SO4 with deep-red colour. Br in chloroform gives C.H.BrN.S [210°] crystallising in needles.

Salts. — B'HCl. [240°]. Needles. — B'H_PtCl. Yellow prisms.—C,H_N_SAg: floc-culent m. cot by coldinary. culent pp. got by adding ammoniacal AgNO3.

Acetyl derivative C.H.AcN.S. [187°]. Got by heating phenyl-thiocarbizine with Ac.O. (F.). An isomeride [74°] (275°), got by heating acetyl-phenyl-hydrazine with CSCl, and benzene (Freund, B. 21, 2468), is converted by boiling with alcohol and HgO into acetyl-phenyl-carb-

Benzoyl derivative C.H.BzN.S. [180°]. Got from the base and BzCl (Fischer). An isomeride [110°] is got by heating NHBz.NPhH

with COCl, in benzene at 100° (F.).
PHENYL THIOCARBONATE THIOCARBONATE [97°]. Formed from NaOPh and CSCL, (Ber green, B. 21, 346). White crystals, sol. alcohol. PHENYL-TRI-THIO-ORTHOFORMATE

CH(SPh)₃. [40°]. Got by boiling aqueous NaSPh with chloroform (Gabriel, B. 10, 185). Thick prisms, sol. ether. Split up by fuming HClAq at 100° into formic acid and PhSII.

PHENYL-THIOGLYCOLLIC ACID C.H.SO., i.e. CH₂(SPh).CO₂H. [62°]. Formed by saponifying its ether, which is got by adding ClCO₂Et to a solution of NaSPh in absolute alcohol (Claesson, Bl. [2] 23, 441; Gabriel, B. 12, 1639). Thin tables, sl. sol. cold water. Oxidised by KMnO₄ to phenyl methyl sulphone (Otto, B. 19, Mano, to puerly merry merry approve (5.7.2), 3138). Salts.—KA'.—NaA'.—BaA'...—CaA'...—MgA'.28aq.—CdA'.2aq.—XnA'.22aq.—PbA'... [60°].
—MnA'.28aq.—CuA'...—AgA' aq: crystalline pp.
—Ethyl ether EtA'. (277°). S.G. ± 1·136;

15 1 127. Amide. [104°]. Tables (from alcohol). References. - AMIDO- and BROMO- PHENYL-THYOOLYCOLLIC ACIDS.

(a)-FHEDYL-THIOHYDANTOIC ACID

C.H., N.SO., i.e. NH., C(NPh). S.CH., CO.H. [148°-152°]. Got by heating aniline with ammonium sulphocyanide, chloro acetic acid, and alcohol (Claesson, B. 14, 732). Needles (from HOAc); m. sol. hot water and ether. Cold NaOHAq converts it into C18H11N2S2O4 [112°-115°] (Liebermann, A. 207, 129).

(B)-Phenyl-thio-hydantoic acid

NHPh.C(NH).S.CH...CO.H. Got by evaporating an alcoholic solution of ammonium chloroacetate and phenyl-thio-urea at 100° (Meyer, B. Decomposes on heating without 14, 1659). melting. Insol. water, alcohol, and ether. Boiling dilute HCl forms CO NPh.CO [148°].

Isomeride d. Phenyl-thio-hydantoin. Di-phenyl-hydantoïc acid

NHPh.C(NPh).S.CH.,CO.H. Got from potassium chloro-acetate and di-phenyl-thio-urea (Lange, B. 12, 597). Yellow octahedra. PHENYL-THIO-ψ-HYDANTOIN C_oH_aN_aOS,

i. C(NH) NPh.CO [178°]. Got from chloro-

acetic anilide and thio-ures, and obtained also by boiling (3)-phenyl-hydantoic acid with HOAo or conc. NH,Aq (Meyer, B. 14, 1661), and by the action of phenyl-cyanamide on thioglycollic acid (Andreasch, B. 15, 324). Needles, sol. NaOHAq.

Phenyl-thio-hydantoin CS</br/>
NPh.CO

NH.CH. by melting glycocoll with phenyl-thiocarbimide (Aschan, B. 17, 424). Monoclinic plates, decomposing near 200°. Boiling alcoholic potash converts it into a salt of an oils phenyl-thio-hydantoic acid NHPh.CS.NH.CH2.CO2H which, when set free, rapidly changes again to phenyl-thiohydantoin.

Di-phenyl-thio-hydantoin C13H12N2SO, i.e. CS NPh.CO ? [176°]. Got from chloro-acetic acid and di-phenyl-thio-urea (Lange, B. 12, 595). Iridescent plates, insol. water, v. sol. not alcohol. Boiling dilute HClAq forms the compound C₀H,NSO₂[148°].—B'₂H₂PtCl₆. Yellow needles.

Di-phenyl-thio-hydantoin CS NPh.CO [233°]. Formed by the action of alkalis on NHPh.CS.NH.CHPh.CO.Et (Kossel, B. 24, 4152). Reference. - OXY-DI-PHENYL-THIOHYDANTOIN.

PHENYL-DI-THIO - DI-METHYL-KETURET NH C(NH).8 CMc₂. [239°]. Formed from phenyl-di-thio-biuret and acetone (Fromm, B.

25, 1278). Sol. alkalis. Converted by benzyl chloride into C,H,N C(NC,H,).S CMe, [128°] which is insol. alkalis.

DI-PHENYL-THIO-OXAMIDE C.S. (NHPh) .. [133°]. Formed from di-phenyl-oxamide l successive treatment with PCl, and H2S (Wal-

lach, B. 13, 527). Golden plates.

(a) PHENYL-THIOPHENE C₁₀H_nS i.e.

Expend by heating either

C.SH₃Ph. [41°]. Formed by heating either Cll.Bz.CH(CO₂H)₂ or A-benzoyl-propionic acid with P.S. (Rues a. Paal, B. 19, 3141). Small tables, insol. water, v. e. sol. ether, v. sol. alcohol. Volatile with steam. With isatin and cold H.SO, it gives a splendid bluish-violet colour, changing to dark blue. Bromine gives rise to $C_{1e}H_aBr_aS$ [56°] and $C_iSBr_a.C_aH_aBr$ [1:4] [146°]. (8) Phenyl-thiophene C_iH_aPhS . [170°].

(330"). A product of the passage of the vapours of toluene and sulphur through a red-hot tube (Renard, C. R. 109, 699). White spangles, m. sol. cold alcohol. Gives a blue colour with isatin and H.SO4, and a green colour with phenanthraquinone and H.SO., Yields C,H₂BrS.C₆H₄Br[1:4] [195°], C,H₄(NO₂)S.C₆H₄,NO₂ [1:4] [178°], a disulphonic acid, and a tetrasulphonic acid.

Di-(a)-phenyl-thiophene SCPh:CH. [153°]

Formed by heating C.H.Bz. with P.S. at 180° (Paal, B. 21, 3058). White plates (from alcohol). Tri-phenyl-thiophene C,Ph,HS. [127°]. Got by heating desyl-acetophenone with P,S, at 150° (A. Smith, C. J. 57, 647). Plates, v. sol. benzene. Gives a greenish-yellow colour with H₂SO₄ and

Tetra-phonyl-thiophene C22H20S i.e. S CPh:CPh. Thionessal. [182°].

isatin or phenanthraquinone.

Formation.—1. By the dry distillation of thiobenzoic aldehyde (Laurent, A. 52, 354).—2. By distilling bensyl sulphide or bensyl di-

sulphide (Märcker, A. 136, 94).-8. By distilling benzylidene sulphide (Fleischer, A. 140, 239; 144, 194) .-- 4. By distilling barium phenyl-acetate with S (Forst, A. 178, 376).—5. By heating phenyl-acetic acid with S for 6 hours at 260° Cliegler, B. 23, 2473) -6. By heating phenyl benzyl ketone with S. -7. By heating s-diphenyl-ethylene with S at 250° (Baumann a. Klett, B. 24, 3311). Minute needles, sl. sol. alcohol, v. sol. benzene and CS. Yields a sulphonic acid, and also the following derivatives: C.,H.,Cl.,S [219°] (Dörn, A. 153, 350), C.,H.,Er,S [265°-270°], C.,H.,(NO.),S [above 250°]. DI - PHENYL - DI - THIO - DI - PHENYL - KE.

TATE CPh.(SPh)₂. Phenyl-mercaptol of benzo-phenone. [139°]. Formed by passing HCl gas into a hot mixture of benzophenone, phenylmercaptan, and ZnCl₂ (Baumann, B. 18, 888). Short prisms, sl. sol. alcohol and ether.

THIOPHOSPHATE PHENYL PS(OPh)_s [49°]. (above 360°). Gobby boiling PSCl₃ with phenol (Schwarze, J. pr. [2] 10, 222) and by heating phenyl phosphate with K.S (Kreysler, B. 18, 1718), or with S at 190° (Anschütz, A. 253. 118). Needles (from alcohol), turning red in air and light. Not decomposed by water.

Phenyl tri-thiophosphate PO(SPh), [72°]. Got by boiling PhSH with POCla. Prisms (from alcohol). Decomposed by warm water.

Phenyl tetra-thio-phosphate 1

tetra-thio-phosphate PS(SPh).. [80°]. Got from PhSH and PSCl,. Silky white needles, not affected by boiling water.
PHENYL THIOSULPHURIC ACID

C.H.S.SO2.OH. Phenyl hydrogen thiosulphate. Got by dissolving Ph₂S in H₂SO₄ (Stenhouse, Pr. 17, 62; A. 149, 254).—BaA', 2aq: crystalline.

PHENYL-THIO-URAMIDO-ACETIC ORTH-

ALDEHYDE. Di-ethyl derivative

NHPh.CS.NH.CH2.CH(OEt)2. [96°]. mixing phenyl-thiocarbimide with amido-acetal NH₂.CH₂.CH(OEt)₂ (Wohl a. Marckwald, B. 22, 569). Needles (from dilute alcohol), insol. water and ligroin, ve sol. other. Cold conc. H.SO. forms NHPh.CS.NH.CH, CH(OH)(OEt) [94°] which yields, by loss of H.O, the salts (C11H11N2SO)2H2PtCle and C11H11N2SOCH3N3O, (190°

PHENYL-THIO-URAMIDQ-BENZOIC ACID v. m-Amido-Benzoic acid.

o-PHENYL - THIO - URAMIDO - CINNAMIC ACID NHPh.CS.NH.C,H,.CH:CH.CO,H. [237]. Formed by heating o-amido-cinnamic acid with phenyl-thiocarbimide on the water-bath (Rothschild, B. 23, 3343).

DI-PHENYL DI. THIOURAMIDO . TETRA. OXY-DI-PHENYL. Tetra-methyl derivative C₁H₄(OMe)₄(NH.CS.NHPh). [184]. Formed from C₂H₂(OMe)₂(NH₂).C₃H₂(OMe)₄(NH.) and phenyl thiocarbimide (Baessler, B. 17, 2128). White flakes, sol. hot alcohol and benzene.

PHENYL-THIOURAMIDO-PHENYL-ACETIC ETHER NHPP.CS.NH.CHPh.CO.Et. [1624]. Formed from phenyl-amido-acetic ether and phenyl-thiocarbimide (Kossel, White crystals, sol. hot alcohol. B. 24, 4151).

PHENYL-THIO-URAMIDO-THIO-FORMIC ACID v. PHENYL-DI-THIO-ALLOPHANIC ACID.

PHENYL . THIOURAMIDO . TOLYL . CARB . AMIC ETHER NHPh.CS.NH.C.H., Me.NH.CO.Et. [155°] Formed, together with CS(NHPh), by the action of phenyl-theocarbimide on amido-

tolyl-carbamic ether (Schiff, B. 23, 1818).

risms (from alcohol), v. sl. sol. alcohol.
DI-PHENYL-DI-p-THIOURAMIDO-DI.
TOLYL-O-SULPHIDE C₂-H₂₈N₄S₄. i.e.
S(C₄H₃Me.NH.CS.NHC₄H₃), Thio-p-tolyt-di-plenyl-thiourca. [134°]. Formed by the action of phenyl-thiocarbimide upon di-p-amido-di-tolyl-sulphide (Truhlar, B. 20, 670). White prismatic needles. V. sol. alcohol, ether, and benzene.

PHENYL-THIO-UREA C.II, N.S i.e. NHPfl.CS.NH... Mol. w. 152. [154°]. S. 26 at 18°; 5 93 at •00°. S. (alcohol) 5.59 at 16°; 68 at 78°.

Formation .- 1. By heating phenyl sulphocyanide with alcoholic NH, (Hofmann, Pr. 9, 27).—2. By boiling aniline with ammonium sulphocyanide Schiff, A. 148, 338; Rathke, B. 18, 3104).—3. By heating aniline sulphocyanide at 190' (Salkowski, B. 24, 2728; cf. De Clermont, C. R. 82, 512).-4. By passing H.S. into a solution of phenyl-cyanamide in benzene Weith, B. 9, 819).

Properties. - Needles, sol. alkalis and reppd. by acids. Tastes bitter.

Reactions .- 1. Heated in a scaled tube at 180° it yields CS(NHPh)2, ammonium sulphocyanide, NH₂, H₂S, and aniline.—2. Ammonia at 140° forms aniline and ammonium sulphocyanide.—3. Boiling aniline forms CS(NHPh),-4. HGlAq at 120° forms aniline, H₂S, NH₃, and CO₂.—5. By boiling with alkaline lead actate solution it gives phenyl cyanamide N:C.NHC,H, which polymerises on heating to tri-phenyl-isomelamine (PhN:C)3(NH)3.-6. When boiled for several hours with freshly-precipitated HgO it yields asymmetrical tri-phenyl-melamine PhN C(NH).NPh C.NHPh (Hofmann, B. 18, 3220). - 7. Cl.CO.CO.Et forms oxalyl-di-phenylbiuret, NH CS.NPh C2O2 (v. Chloro-GLY-OXYLIC ETHER) .- 8. ClCO .Et forms phenyl-thioallophanic ether .- 9. Silicon tetrabromide gives solid SiBr₄(C,H₈N₂S)₄, sol. hot benzene, but decomposed by boiling alcohol (Reynolds, C. J. 53, 856).—10. An alcoholic solution of allyl by comp.—10. An alcoholic solution of alliptomide forms a base C₁₀H₁₂N₂S (Werner, C. J. 57, 362).—11. Benzyl chloride in algebol.—forth CS(N₂H₃Ph)C,H,Cl [112°] (W.).—12. Ethylene bromide forms C₁₀H₁₈N₂S [139°], which gives the salts B"2HBF [214°], B"2HCl [218°], B"H_PtCl₁₈D, B"30 [14] (N.). Out 1160° (B.). and B"2C_aH₂(NO₂)₂OH [196°] (Bertram, B. 25, 59).—13. H₂O₂ oxidises it, in alcoholic solution, to di-phenyl-di-amido oiazthiole (Hector, B. 22. 1176).

Salts. -B'₂H.PtCl₆.-B'₆Cu₂Cl₂ 6aq. [145°] (Rathke, B. 17, 305). Trimetric crystals (from alcohol).

Acetylderivative NHPh.CS.NHAc. [173°]. Formed from acetyl sulphocyanide and aniline (Miguel, A. Ch. [5] 11, 318), and by the action of Ac2O on the product of the action of phenyl thiocarbimide on aldehyde-ammonia (Schiff, B. 9, 570). Tables (from delute alcohol).

—B'HBr. [270°]. Prisms, v. e. sol. water.

Benzoyl derivative NHPh.CS.NHBz. [149°]. S. (alcohol) 4 at 78°. Needles, insol. water (Miguel).

o-Oxy-bensoyl derivative NHPh.CS.NH.CO.O.H.OH. [192°]. Formed from salicyl-thiocarbimide and aniline (M.).

Di-phenyl-thio-ures C, H,2N,S i.e. CS(NHPh), Mol. w. 228. [151°] (Lellmann, A. 221, 21; Losanitsch, B. 19, 1821).

Formation .- 1. By boiling aniline with CS. and alcohol (Hofmann, A. 57, 266; 70, 144). 2. By heating aniline with potassium sulphocyanide and H,SO, (Laurent a. Gerhardt, A. Ch. [8] 22, 103; 24, 196). — 3. From aniline and phenyl-thiocarbimide.—4. From di-phenyl-cyan-amide and H₂S (Weith, B. 7, 1303).—5. By boil-ing s-di-phenyl-guanidine with CS₂ (Hotmann,

Properties .- Trimetric crystals (from alcohol), nearly insol. water, v. sol. alcohol and ether. Sol. alkalis and reppd. by acids. Has a

very bitter taste.

Reactions.—1. Partially decomposed on dis-tillation into tri-phenyl-guanidine, CS₂, and H,S.-2. P,O,, ZnCl,, or HCl split it up into aniline and phenyl-thiocarbimide. -3. Roiling alcoholic potash forms di-pheny urea. 4. Diphenyl-ures is formed when the alcoholic solus tion is boiled with HgO. -5. A cold solution of nitrous ether in alcohol forms tri-phenyl-guanidine, phenyl thiocarbimide, and S (Claus, B. 4, 143).—6. Iodine, added to its boiling alcoholic solution, forms tri-phenyl-guanidine and phenyl thiocarbimide. - 7. Aniline forms, on heating, tri-phenyl-guanidine and H,S.-8. Sodium. amalgam reduces it to aniline, H2S, and CH, (Merz a. Weith, Z. [2] 4, 612).—9. When heated with HgCl, it yields tri-phenyl-guanidine (Buff, 2, 498).—10. Fuming H₂SO, decomposes it on heating, forming aniline, COS, and SO2 (Fleischer, B. 9, 998).—11. COCl, forms C, Hi, N, SO [87°], crystallising in prisms and split up by heat into COS and di-phenyl-cyanamide (Will, B. 14, 1486).—12. CSCl₂ in benzene forms C₁H₁₀N₂S₃, orystallising in yellow needles [156°], sl. sol. alcohol. In presence of ether CSCl2 forms alcohol. In presence of emer CSO₁₂ forms NPh:C \langle NPh>CS [79°] (Freund a. Wolf, B. 25, 1459).—13. H₂S at 170° forms aniline and CS. (Weith, B. 7, 1304).—14. Alkyl iodides form alkyl derivatives, which may perhaps be formulated as derivatives of ψ -thio-urea. Thus, MeI forms HEP. C(SMe):NPh [110], which is decomposed by hear int. MeSH and C(NPh), and by alcoholic potash into MeSH and CO(NHPh). like manner EtI forms C1.3H1.6N2S [79°] (v. DI-PHENYL-ETHYL- ψ -THIO-UREA), and ethylene bromide gives $C_{1b}H_{11}N_{2}S$ [136°] (Will, B. 14, 1490).— 1b. Allyl bromide in alcohol yields C, H, N, SBr, erystallising in trimetric prisms [171°] (Werner, orystanising in trimetric prisms [1:1] (Werner, C. J. 57, 303).—16. Benzyl chloride in alcohol forms C₂₀H₁₈N₂SO, crystallising in prisms [153°] (W.).—17. Phenyl cyanate in presence of benzene at 180° forms di-phenyl-ures and phenyl-ures. ene at 180° forms di-phenyl-urea and phenyl sulphocyanide (Goldschmidt a. Meissler, B. 23, 271).—18. Ac,O yields acetanilide and some phenyl-thiocarbimide (Werner, C. J. 59, 398).—19. Chloro-glyoxylic ether forms di-phenyl-di-thio-parabanic acid C₀-H₁,N₂S,O₂ [215°] and O₁-H₁,N₂S,O₂ [215°] and O₂-H₁,N₂S,O₃ [215°] and O₃-H₂,N₃S,O₄ [215°] and O₃-H₃,N₃S,O₄ [215°] and O₃-H₃ [215°] and O₄-H₃,N₃S,O₄ [215°] and O₅-H₃ [2 [235°] (Stojentin, J. pr. [2] 32, 8).

Tri-phenyl-thio-urea NHPh.CS.NPh,. [1529]. Formed by heating phenyl-thiocarbimide with diphenylamine at 280° (Gebhardt, B. 17, 2092, 3036). Long white needles, v. sol. hot alcohol.

3036). Long white needles, v. sol. not account.

Tetra-phenyl-thio-urga CS(NPh.)₂. [1967].

Formed by heating tetra-phenyl-guanidine with CS, at 270°; the yield being 60 p.c. of the theoretical amount (Bernthsen a. Friese, B. 15, 1530). Formed also from NHPh, and CSCl. (Bergreen, B. 21, 340). Long needles, sol. hot alcohol, insol. alkalis. Yields diphenylamine on heating with diluted (70 p.c.) H.SO.

Di-phenyl-thio-drea v. DI-PHENYL-DI-PHENYL-THIO-UREA.

References .- AMIDO-, BROMO-, CHLORO-, IODO-, NITRO, and OXY- PHENYL-THIO-UREA.

PHENYL-THIO-UREA CAMBON 7.
v. m-Amido-benzoto acid, Reaction 7.
DI-PHENYL-TOLENYL-AMIDIFE C. H₁₈N₂
Of by i.e. C.H.Me.C(NPh).NHPh. [168°]. Got by warming C.H.Me.C(NEt):NH2CI with aniline and alcohol (Glock, B. 21, 2656). Plates (from benzene), v. sol. alcohol.

PHENYL-TOLUENE v. METHYL-DIPHENYL. DI-PHENYL-TOLUIC ALDEHYDE C. HISO i.e. CPh2H.C6H1.CHO. [-15°]. (190°-195° at 46 mm). Formed by heating terephthalic aldehyde with benzene and conc. H₂SO₄ at 100° (Oppenheimer, B. 19, 2028). Oil. Reduces ammoniacal AgNO₃, being itself oxidised to tribunal mathena and should be a support of the support phenyl-methane carboxylic acid. KMnO4 gives tri-phenyl-carbinol p-carboxylic acid. Reacts with phenyl-hydrazine. Yields C, H16ONaHSO,

PHENYL-0-TOLUIDINE C₁H₁N t.e. [1:2]C,H,Me.NHPh. [41^o]. (805^o i.V.) at 728 mm. (Graebe, A. 238, 368). Formed, together with NHPh and distallaring the particular telescope. with NHPh, and ditolylamine by heating o-toluidine with aniline hydrochloride at 280° (Girard a. Willm, Bl. [2] 25, 248). Coloured violet-blue by HNO,

Phenyl-m-toluidine. (300°-305°). Got by rnenyi-m-toluidine: (300°-305°). Got by heating [1:3:5] C₀H₂Me(NHPh). OH with zincdust (Zega a. Buch, J. pr. [2] 33, 542). Oil. Coloured green by H₂SO, containing HNO₂.

Phenyl-p-toluidine C.H., NHPh. [879].

(318° i.V.) at 728 mm. (Graebe, A. 238, 363). Formed by distilling tri-tolyl-rosaniline acetate (Hosmann, A. 132, 291). Obtained also, together with diphenylamine and ditolylamine by heating p-toluidine (1 mol.) with aniline (1 mol.) and HCl (1 mol.) at 230° (De Laire, Girard, a. Chapoteaut, Bl. 1867, i. 360; A. 140, 347). Prepared by heating phenol with p-toluidine and ZnCl, or p-ore-sol with aniline and ZnCl, at 200° or with SbCl, (Buch, B. 17, 2634). Crystals. Coloured blue by HNO. With benzoic acid and ZnCl2 at 260° it yields phenyl-methyl-acridine C20 H13N (Bonna, A. 239, 60). Bromine vapour forms a tetra-A. 239, 60). Bromine vapour acting a lesson bromide [135°], a hepta-bromo derivative [185°], and a compound NC₁₃H₁₂Br, or NC₁₃H₂Br, and a compound NC₁₃H₁₂Br, and a compound NC₁₃H₂Br, Br. 254°]. Excess of Br at 310° forms NC₁₃H₂Br₁₃ [296°] (Bonna). Bromine in HOAc added to an alcoholic solution forms a tetra-bromo-derivative f15697.

Salt .- B'HCl: plates.

Acetyl derivative O.H., Acn. [519].
Yields C., H., BrAcn. [729], crystallising in plates.
Bensoyl derivative O.H., NO. Crystals
Yields crystalline C.H. (NO.). NBz. C.H., NO.
Nitrosamine C.H., NPh. NO. [829]. Yellow

medles (from ligroin). Br forms C₁₂H₁₁BrN₂O [166°] (Bonna, A. 239, 56).

PHENYL-TOLYL-ACETAMIDINE C₁₃H₁₄N₂ i.e. CH₂C(NC,H₁).NHPh. (76°). Formed from acetyl p-toluidine by successive treatment with PCl₃ and aniline (Wallach a. Fassbender, A. 214, 206).—B'₂H₂PtCl₄.

PHENYL-p-TOLYL-ACETIC ACID

C,H,CHPh.CO,H. [115°]. Formed from abromo-phenyl-acetic acid, toluene, and zincdust (Zincke, B. 10, 4916; Neure, A. 250, 149). Plates (from water), v. sol. alcohol.—KA' 4aq.—NaA' 6aq.—CaA' 2aq: needles (from dilute alcohol).

Ethyl ether EtA'. [34°]. Plates. Amide C₁₈H₁₈NO. [151°]. Nitrile C₇H₇CHPh.CN. [59°].

Phenyl-di-tolyl-acetic acid C. H., O. 178°-83°]. Got by oxidising (C.H.), CPh.CQ.C.H., (Thorner, A. 189, 123). Amorphous powder, insol. water, v. sol. alcohol.

PHENYL-TOLYL-AMINE v. PHENYL-TOLU-

PHENYL-p-TOLYL-BENZYL-BIURET NHPh.CO.N(GH,Ph).CO.NHC,H Me. [c. 100°]. Formed from p-tolyl-benzyl-urea and phenyl cyanate (Kühn a. Henschel, B. 21, 505). Needles

PHENYL-p-TOLYL-BENZYL-UREA

 $C_{21}H_{20}N_2O$. [113]. Got from p-tolyl-benzyl-carbanic chloride and aniline (Hammerich, B. 25, 1823). Dimorphous: prisms or plates, solether and alcohol.

PHENYL-DI-p-TOLYL-BIURET C_xH_{x1}N_xO_x i.e. NHPh.CO.N(C_aH₁Me).CO.NHC_aH₄Me. [140°]. Formed by heating di-p tolyl-urea with phenyl cyanate at 170° (Kühn a. Henschel, B. 21, 505). Crystals (from alcohol).

Di-phenyl-tolyl-biuret

(from dilute alcohol).

NHPh.CO.NPh.CO.NHC.W.Me. [216°]. Got by heating di-phenyl-urea with p-tolyl cyanate at 170° (K. a. H.).

PHENYL-p-TOLYL-CARBINOL C₁₁H₁₁O i.e. C₂H₁Me.CPhHOH. [53°]. Got by reducing phenyl tolyl ketone in alcoholic solution by sodium-amalgam (E. a. O. Fischer, A. 194, 265). Stellate groups of needles (from ligroin).

Di-phenyl-tolyl-carbinol C_∞H_{1N}O i.e. • C_∗H₄Me.CPh..OH. [150°]. Formed by oxidising di-phenyl-tolyl-methane with CrO, and HOAc (F.). Crystals (from ligroïn). May be distilled.

PHENYL-p-TOLYL-CARBINOL O-CARB-OXYLIC ACID. Lactone v. Tolyl-Phthalide. Di-phenyl-tolyl-carbinol carboxylic acid.

Lactone $\begin{bmatrix} 5_1^2 \end{bmatrix}$ C₆H₃Me<CO^{Ph₂}>O. [147°].

(above 360°). Formed by oxidising di-phenylm-xylyl-methane with chromic acid mixture (Hemilian, B. 16, 2361; 19, 3063). Prisms.

The isometic [42] C₆H₁Me C^{CPh}_{CO} O₁ [179°], (above 360°), is got by oxidation of diphenyl-p-xylyl-methane, and is accompanied by [1:2:5]OPh₂(OH).O₂H₁Me.OO₂H₁, which yields BaA'₂ and CaA'₂, and does not form a lactone.

PHENYL-o-TOLYL-CARBINYLAMINE
[1:2]C₀H₄Me₄CHPh.NH₂ (299°) at 721 mm.
Formed by reducing the oxim of phenyl o-tolyl ketone dissolved in alcohol by adding sodium-

amalgam and HOAc (Goldschmidt a. Stöcker, B. 24, 2806). Yields an acetyl derivative [124°].

R'HCl. [249°]. Needles, m. sol. water.

-B'HCl. [249°]. Needles, m. sol. water. • m. Isomeride. (299°) at 724 mm. Yields 'HCl [243°] and an acetyl derivative [97°].

m-neumerage. (2997) as 724 mm. Helds B'HCl [248°] and an acetyl derivative [97°]. p-Isomeride. (296°) at 723 mm. Yields an acetyl derivative [181°] and the salts B'HCl [252°], B'_LH_PtCl, 2aq [119°], B'C,H_O, [157°], B'C,II,O, [73°]. The hydrochloride is converted by potassium sulphocyanide into the compound 'C,H_Me.CHPh.NH.CS.NH, [101°] and by potassium synante into the urea derivative C,H_Me.CHPh.NH.CO.NH, [158°].

PHENYL TOLYL - CARBINYL KETONE CARBOXYLLC ACID Challing i.e. Call Me.CH., CO.L. [112°]. Formed by heating Call. (CH.Calline) O with KOHAq at 100° (Heilmann, B. 23, 3160). Vitreous prisms.—AgA'. Converted by heating with an alcoholic solution of hydroxylamine hydrochloride into Call. (CGII...Calline) N

PHENYL-o-TOLYL-CYANAMIDE

NPh:C:NC_aH,Me. Carbophenyltolytimide. (320°-325° uncor.). Formed by adding HgO to a boiling solution of phenyl-o-tolyl-thiouses in dry benzene, the yield being 65 p.c. of the theoretical. Oil. On keeping, it polymerises to a brittle glassy solid [68°-71°]. V. sol. benzene, sl. sol. ether. By boiling with dilute alcohol it is converted into phenyl-o-tolyl-urea. H₂S passed into its boiling solution in dry toluene converts it into phenyl-o-tolyl-thiourea. Heated with CS₂ at 180°-200° it yields a mixture of phenyl- and o-tolyl-thiocarbinides. It combines with o-toluidne, forming u-phenyl-dio-tolyl-guanidine (Huhn, B. 19, 2410).

Phenyl-p-tolyl-cyanamide NPh:O:NO,H,, (325°-330° uncor.). Resembles the preceding isomeride in mode of preparation and properties.

DI-PHENYL-TOLYLENE-TETRA-AMIDO-METHANE C₂₀H₂₂N₄ i.e.

C₁H₀\NH\ NH\ C(NHPh)₂(?). [161°]. Formed by heating C(NPh)₂ with tolylene-o-diamine at 1282 (Dahm a. Gasiorowski, B. 19, 3057. Needles (from henzene).—B'₃BHCl. [174°].—B'H₂SO₀.

DI-PHENYL-m-TOLYLENE DIAMINE $C_{1p}H_{1s}N_2$, i.e. $[1:3:5]C_sH_1Me(NPhH)_2$. $[105^\circ]$. Formed by heating orein (1 pt.) with aniline (4 pts.) and a mixture of $2nCl_2$ and $CaCl_2$ at 220° (Zega a. Buch, $J.\ pr.\ [2]\ 33,\ 542$). White needles (from glacial HOAc).

Di-acetyl derivative [160°].
Di-benzoyl derivative [190°].
Dinitrosamine C₁₁H₁₆N₁O₂ [170°].
Reference. — DI-NITRO-PHENYL-TOLYLENE-DI-

PHENYL-o-TOLYLENE-GUANIDINE

C,He\NH\C:NPh. [167°]. Mol. w. 229 (calc. 22:i). Formed from o-tolylene-diamine and diphenyl-cyanamide (Keller, B. 24, 2514). Needles (from warm alcohol). Di-p-tolyl-cyanamide

forms C,H, C:NPh C(NHC,H.), [193°], while phenyl cyanide gives the compound

>0:NPh [234°].-B'HCl.~

B', H, PtCl. -B', H, SO,: white needles.

Mono-acetyl derivative. [147]

Di-benzoyl derivative. [2220]. Prisms. Nitrosamine C₁₄H₁₂N₄O. [125°]. DI-PHENYL-m-TOLYLENE-DI-METHYL-

DI-AMINE C₂₁H₂₂N₂i.e. C_cH₃Mc(NPhMe)₂ [124°]. Formed from C₂H₆(NHPh)₂, NaOH, and McI (Zega a. Buch, J. pr. [2] 33, 546). White lamine (from HOAc).

DI - PHENYL-o-TOLYLENE - DI - THIO - DI-UREA [1:3:4]C.H.Me(NH.CS.NHPh)2. [c. 150°]. Formed from tolylene-o-diamine and phenylthiocarbimide in alcohol (Lellmann, A. 221, 19). Thin plates (from dilute alcohol), v. sol. waren NaOHAq, sl. sol. water.

Di-phenyl-m-tolylene-di-thio-di-urea

[1:2:4]CaHaMe(NH.CS.NIIPh), [168°]. Formed from tolylene-m-diamine and phendl thio-carbimide (Lussy, B. 8, 670; Gebhardt, B. 17, 8046; Billeter a. Steiner, B. 18, 3293; 20, 228).

Di-phenyl-p-tolylene-di-thio-di-urea [1:2:5]C₆H₃Me(NH.CS.NHPh)₂. [181°] a Formed from tolylene-p-diamine and phenyl-thiocarbimide in alcohol (Lellmann a. Würthner, A. 228, 206). Plates, nearly insol. alcohol. DF-PHENYL-TOLYLENE-DI-UREA

C,H_s(NH.CO.NHPh)_z. [above 300°]. Formed by adding phenyl cyanate to an othercal solution of tolylene-diamine [99°] (Kuhn, B. 18, 1477). white pp. Insol. water, alcohol, ether, and benzene, v. sl. sol. acetic acid. By boiling with aniline it yields s-di-phenyl-urca.

PHENYL-p-TOLYL-ETHANE C₁₃H₁₆, i.e.

C₁₅H₁₆, (286° un CH₂Ph.CH₂.C. H₄Me. [27°]. (286° uncor.). Formed by reduction of tolyl benzyl ketone by HI and P (Mann, B. 14, 1646). White plates.

Phenyl-p-tolyl-ethane CH3.CHPh.C,H,Me. (279°). Formed from CaH3.C2H4Br, toluenc, and zinc-dust (Bandrowski, B. 7, 1016). Oil. Yields p-benzoyl-benzoic acid on oxidation.

PHENYL-p-TOLYL-ETHYLENE C,5H, i.e. CIIPh:CH.C.H. Methyl - stilbene. Formed by boiling p-tolyl-benzyl-carbinol with dilute H.SO, (Mann, B. 14, 1646), and also by Section 25.4 (January B. 17, 1976), and also by Garding p-tolyl cinnamate (Anschütz, C. J. 47, 898; B. 18, 1945). Pearly plates with blue fluorescence, v. sl. sol. alcohol, v. c. sol. ether. Yields

C_{1.}H_{1.}Br₂ [187°]. DI - PHENYL - DI - p - TOLYL - ETHYLENE OXIDE? C₂₈H₂₁O. Phenyl tolyl (a)-pinacolin. [215]. Formed by the action of zinc and HClAq on phenyl p-tolyl ketone in alcohol, and got also by heating a mixture of the ketone with phenyl-tolyl-carbinol, alcohol, and ZnCl, (Thorner a. Zincke, B. 11, 71; A. 189, 104). Minute needles, m. sol. hot alcohol. Conc. HClAq at 150°

changes it into the isomeric (β)-pinacolin C,H,CO,CPh(C,H,Me), [187°].

PHENYL P-TOLYL ETHYLENE DISUL-PHONE C,H,SO,C,H,SO,C,H, [162°]. Got by boiling C,H,NO,C,H,Cl with an alcoholic solution of sodium toluene p-sulphinate (Otto, J. pr. 1320, 103).

[2] 80, 199).
PHENYL - TOLYL - ETHYLENE - \psi - THIO-UREA NPh:C<N(C,H₁)>CH₂. [128°]. Formed by boiling the methylo-iodide of the ethylene derivative of tolyl-di-thio-carbamic acid with

aniline (Will a. Bidschowski, B. 15, 1315). Silky plates.

PHENYL - p - TOLYL - ETHYL - THIO-UREA C₁₆H₁₈N₂S, i.e. NPhEt.CS.NHC,H. [90°]. Formed from p-tolyl-thiocarbimide and ethyl-aniline (Gebhardt, B. 17, 2091). Colourless crystals.

s-PHENYL-DI-o-TOLYL-GUANIDINE

C₈H₃N:C(NHC₇H₇)₂. [102°]. Formed by the action of an alcoholic solution of aniline upon di-o-tolyl-thiourea in presence of PbO. Got also by the combination of C.H., N:C:N.C,H, with amiline (Huhn, B. 19, 2412). Folted needles. V. sol. warm abohol, ether, and benzene.

B'HCl.—B',H₂Cl,PtCl₄: orange-yellow tables.

u-Phenyl-di-o-tolyl-guanidine
C,H,N:C(NHC,H,)(NHC,H), [112°]. Formed from o-toluidine and C,H,N:C:NC₆H₃ (Huhn). Long needles, v. sol. alcohol. Salts .- B'HCl. -

B'₂H₂FtCl₄: orange-yellow tables. s.Di-phenyl-p-tolyl-guanidine C.H,N:C:(NHC₆H₅)₂. [121°]. Formed by the action of an alcoholic solution of p-toluidine upon di-phenyl-thiourea in presence of PbO (Hofmann, B. 2, 459; Huhn, B. 19, 2412). Felted needles. V. sol. alcohol and ether.— B'HCl.—B'₂H₂Cl₂PtCl₄: reddish-yellow pp. *u*-Di-phenyl-p-tolyl-guanidine C₂₀H₁₉N₂, *i.e.*

C,H,N:C(NHC,H,)(NHC,H,). [127°].

Formation. -1. By heating phenyl-p-tolylthiourea with an alcoholic solution of aniline in presence of PbO.-2. By the combination of C.H.N:C:NC,H, with aniline (Huhn, B. 19, 2109). -B'HCl. -B'2H2Cl2PtCl1: sparingly soluble pp.

PHENYL TOLYL-IMIDO-BENZYL KETONE C₆H₅.CO.C(NC₇H₇).C₆H₅. Formed by heating o-toluiding with benzil at 100° (Bandrowski, M. 9, 689). Yellow plates (from alcohol).

PHENYL O-TOLYL KETONE C14H12O i.e. C_aH₅.CO.C_bH₁Me [1:2]. (314°) at 735 mm· (Smith, B. 21, 4046); (295°) at 722 mm. (G. a-S.). Formed by the action of AlCl, on a mixture of o-toluic chloride and benzene (Ador a. Rilliet, B. 12, 2301; Goldschmidt a. Stöcker, B. 24, 2805). Formed also, together with a much larger quantity of the p- isomeride, from BzCl, toluene, and AlCl3 (Elbs, J. pr. [2] 35, 466). Oil. Yields anthracene on long boiling or on heating with zinc-dust.

'syn-Oxim C,H,,C.C,H,. [69°]. HO.N

Phenyl-m-tolyl ketone C, H, CO.C, H, Me [1:3]. (315° i.V.) at 745 mm. S.G. 17.6 1.088. Formed by the action of AlCl₃ on a mixture of *m*-toluic chloride, benzene, and AlCl₃ (A. a. R.; G. a. S.). Got also by cautious oxidation of phenyl-m-tolyl-methane (Senff, A. 220, 252). Oil, miscible with alcohol. Reduced by HIAq at 200° to C,H, (269° at 725 mm.). Oxim. [101°].

Reduced by sodium-amalgam in presence of HOAc to m-toluic anilide and

gam in presence of HOAC to me some anime and O.H., Mc.CPh.H.NH.,
Phenyl.p-tolyl ketone C.H., CO.C.H., Me [1:4],
[60°]. (327° i.V.).

Formation.—1. Togethet with the o-isomeride

Formation.—1. Togethet with the o-isomeride

by heating benzoic acid with toluene and P2O, at 200° (Kollarits a. Merz, B. 6, 446; Thörner, A. 189, 83).—2. By oxidising C.H.Me. 6PhH. (Zincke a. Plascuda, B-7, 982).—8. By distilling a mixture of calcium p-tolunte and benzoate (Radziszewski, B. 6, 810).—4. By heating BzCl with toluene and zinc at 190° (Grucarevic a. Merz, B. 6, 1243) .- 5. By the action of AlCl. on a mixture of p-toluic ahloride and benzene (A. a. R.).—6. From BzCl, toluene, and AlCl.

Properties.—Prisms, m. sol. alcohol, v. sol. ether. Dimorphous. Yields p-benzoyl-benzoic acid on oxidation. Reduced to C,H,Me.CH,Ph acid on oxidation. Reduced to C_{11} Met. C_{12} In by distillation over zinc dust. Sodium amalgam forms phenyl-tolyl-carbinol. Zinc and HClAq acting on the alcoholic solution form two pinacolins C_{12} H_{24} O. The (α) -pinacolin (215°) may be converted into the (8)-isomeride [137°] by heating with HOAc.

C_eH₄.C.C_eH₄Me. HO.N anti-Oxim [154°]

(Hantzsch, B. 23, 2325, 2776; 24,658; cf. Wegerhoff, A. 252, 11). Converted by HOAc and HCl into p-toluic anilide. Yields an acetyl derivative[124°] and a benzoyl derientive [85°] (Auwers, B. 23, 399).

syn-Oxim C.H.,C.C.H.Me. [116°]. Con-N.OH

verted by HOAc and HCl into benzoyl-toluidine and some toluic anilide. Yields an acetyl derivative [118°-122°] and a benzyl derivative [51°].

Phenyl p-tolyl diketone C_aH₃CO.COC,H₃.
Formed by heating di-bromo-deoxybenzoïn with water at 183° (Bucher, B. 22, 2819). Yellow oil, solidified by cold.

References .-- DI-AMIDO-, NITRO-, OXY-AMIDO-, and Oxy. PHENYL TOLYL-KETONE.

PHENYL TOLYL KETONE CARBOXYLIC ACID v. Toleyl-BENZOIC ACID.

Phenyl p-tolyl ketone dicarboxylic acid C₁₆H₁₂O₆ i.e. C₆H₅.CO.C₆H₂Me(CO₂H)₂ [1:4:2:6]. Benzoyl-uvitic acid [245°]. Formed by oxidising phenyl mesityl ketone with dilute HNO, (Elbs, J. pr. [2] \$5, 489). Needles.—Ag₂A".

An isomeric acid, got by oxidation of phenyl ψ-cumyl ketone C_cH₃.CO.C_cH₂Me₁ [5:1:2:4], yields

PHENYL-o-TOLYL-METHANE C₁₄H₁₄ i.e. C₄H₄,CH₄,C₈H₄Me [1:2]. o-Benzy'-toluene. Mol. w. 182. (284°). Formed, together with the p-isomeride, by heating benzyl chloride with toluene and zinc-dust (Zincke, B. 6, 906; Senff, A. 220, 249). Got also from C.H.Mc.CH.C.P. benzene, and zinc-dust (Barbier, B. 7, 1544). Yields anthracene when passed through a redhot tube.

Phenyl-m-tolyl-methane

C₆H₈.CH₂.C₆H₄Me [1:3]. (275° i.V.). S.G. 17.6 .997. Got by reducing the ketone with HI and P (Ador a. Rilliet, B. 12, 2300). Prepared by heating ω -chloro-m-xylene (1 pt.) with benzene (7 pts.) and AlCl, (Senff, A. 220, 230; cf. Barbier, C. R. 79, 660). Oil, sol. alcohol and ether. Gives a di-nitro- derivative [141°].

Phenyl-p-tolyl-methane
C₄H₃.CH₄.C₄H₄Me [1:4]. (280° i.V.). Formed,
with the o-isomeride, by heating benzyl chloride,
with toluene and zinc-dust (Zincke, B. 7, 1163; A. 161, 98). Formed also by the action of zincdust on benzyl chloride (Prost, Bl. [2] 46, 248), and by heating phenyl p-tolyl ketone with ammo-nium sulphide and S at 320° (Willgerodt, B. 20, 2470). Gil. Yields p-benzoyl-benzoic acid on oxidation. Does not form anthracene when Vol. IV.

passed through a red-hot tube. Yields a disulphonic scid [38°], which gives K,A" 3 aq,
BaA" 8 aq, and CuA" 4 aq.

Pheny di-tolyl-methane CHPh(C,H,), [56°]. Got by heating (C,H,), CPh.CO.C,H, with sodalime at 300° (Thorner a. Zincke, B. 11, 70).

Di-phenyl-o-tolyl-methane C₂₀H₁₁ i.e. (C₄H₃, CH.C₄H₄Me. [59·5°]. (B54°). Formed from leucaniline by diazotising and boiling with alcohol (Fischer, A. 194, 282; Rosenstiehl a. . Gerber, A. Ch. [6] 2, 342). Spherical groups of prisms (from McOH), v. sol. ether. Oxidised by CrO₂ and HOAc to $(C_cH_a)_2C(OH).C_cH_4Me$ [150°].

ni-pheny m-tolyl-methane. [62°]. (above 3609). Formed by distilling its carboxylic acid with baryta (Hentilian, B. 16,-2368). Long thin needles (from alcohol), v. sol. ether. The crystals emit light when powdered. Its dilute solutions fluoresce blue.

Di-phenyl-p-tolyl-methane. [71°]. (above 36(*). Formed by distilling its o-carboxylic acid, and also by the action of P2O, on a mixture of toluene and di-phenyl-carbinol or of benzene and phenyl-p-tolyl-carbinol (Hemilian, B. 7, 1209; 19, 3066; Fischer, A. 194, 263). Needles or prisms, v. sol. hot alcohol.

References - DI-AMIDO-, CHLORO-, NITRO AMIDO, and OXY- PHENYL-TOLYL-METHANE. PHENYL p TOLYL METHANE -0 CARB OXYLIC ACID C₀H₁Me.CH₂, C₀H₄, CO₂H₄ [134°], Formed by warming C₀H₄Me.CO.CH₄CO.H with NII, Aq and zinc-dust (Gresly, A. 234, 236). Needles (from alcohol), nearly insol. water .-BaA',: plates, v. sol. water.

Phenyl-tolyl-methane dicarboxylie CO_H.C₆H₄.CH(C,H₇).CO₂H. [154°]. ((above 300"). Got by saponifying the nitrile, which is prepared by treating an alcoholic solution of CN.C. H, CH, CN with benzyl chloride and KOH (Eichelbaum, B. 21, 2679). Prisms, sol. alcohol.

Amide. [224]. Small plates.

Imide C₆H. CH(C₇H₇) > CO.

(above 300°). Got by heating the amide with conc. HClAq. Needles, v. sol. alcohol.

Nitrile. [110°]. (above 300°). Plates.

Di-phenyl-p-tolyl-methane carbox be cond C.H.Me.CHPh.C.H., CO.H. [155°]. Formed by warming p tolyl-phthalide with benzene and AlCl, (Gresly, A. 234, 242). Needles (from alcohol).—BaA', 21aq: sl. sol. water.

Di-phenyl-p-tolyl-methane carboxylic acid CIIPh₂.C₆H₄Mc.CO₂H[4:2:1]. [217°]. Formed from di-phenyl-p-tolyl-carbinol carboxylic acid, NaOHAq, and zinc-dust (Hemilian, B. 16, 2363). Transparent tables, v. sol. alcohol. -BaA', 4aq. AgA': minute needles, insol. water.

Di-phenyl-p-tolyl-methane carboxylic acid CHPh...C, H, Me.CO, H [4:1:2]. [203°]. Formed from di-phenyl-methyl-phthalide, NaOHAq, and zinc-dust (Hemilian, 3. 19, 3064). Needles or

zinc-dust (Hemilian, %. 19, 3064). Needles or tables, sol· hot alcohol.—BaA', 3aq.—AgA'.

PHENYL-p-TOLYL DI.METHYMENE DI.

SULPHONE KETONE C., H., S.O., i.e.
C.H., SO., CH., CO.CH., SO., C.H., Me. [112°].

Formed from CH, Br. CO.CH., SO., C.H., Me by treatment with C.H., SO., Na and obtained also from C.H., SO., CH., CO.CH., Br and C.H., Me. SO., Na (Otto, J. pr. [2] 36, 427). Plates, m. sol. alcohol v. sol. CHC! hol, v. sof. CHCl...

PHENYL - o - TOLYL - METHYL - PYRROLE (a. Ebenhardt, B. 23, 3271). They are oils, NC,H, CPh:CH . [44°]. (827°). Formed by heating its carboxylic acid [199°] Lederer a.

Paal, B. 18, 2596). Plates, v. e. sol. alcohol.

Phenyl-p-tolyl-methyl-pyrrole. [91°].
(above 350°). Got by heating its carboxylic acid

Tables (from ligroin).

PHENYL - 0 - TOLYL - METHYL - PYRROLE

CARBOXYLIC ACID C.H.MeN CPh:CH [199°]. Got by saponifying its ether, which is formed by boiling acetophenone-acetoacetic sther with o-toluidine and HOAc (Lederer a. P.c.al, B. 18, 2596). Small prisms (from alcohol).
p-Isomeride. [227°]. Made in like in oner from p-toluidine. Plates, v. sol. alcohol.

Ethyl ether Eth. [115°]. Crystals. PHENYL-0-TOLYL-METHYL-THIO-UREA C₁₃H₁₆N₂S i.e. NMePh.CS.NHC,H,., [121°]. Formed from methyl-aniline and o-tolyl-thiocarbimide (Gebhardt, B. 17, 2091, 3035). Plates.

Phenyl-p-tolyl-methyl-thio-urea. Formed in like manner from p-tolyl-thiocarb-imide (G.). Small trimetric tables. By disti-lation with steam it is resolved into the parent substances, which slowly recombine in the dis-

THENYL-TOLYL-NAPHTHYL-GUANIDINE C₂,H₂,N₂ i.e. CN₂H₂Ph(C,H₂).C₁₀H₂. [belowe 60°]. Formed by boiling an alcoholic solution of phenyl-tolyl-thio-urea and naphthylamine with Pbo (Tiemann, B. 3, 6). Brittle resin,

forming a crystalline hydrochloride. PHENYL-DI-TOLYL-PHOSPHINE

PHENYL-DI-TOLYL-PHOSPHINE

(C₄H₄Me)₂PC₆H₁, [57°]. Formed from p-bromotoluene (2 mols.), C₄H₄PCl₂ (1 mol.), and Na

(Dörken, B. 21, 1512). Crystals, v. sol. ether.

Di-phenyl-tolyl-phosphine C₄H₆P(C₆H₅)₂PCl,

[68°]. Formed from (C₆H₃)₂PCl,

p-bromotoluene, and sodium (Dörken, B. 21, 1511).

Small prisms. Yields (C₆H₃)₂PC(C₆H₄Me)

[180°] and (C₆H₃)₂PS(C₆H₄Me) [139°].

PHENYL-TOLYL-(a)-PINACOLIN C₆₀H₂₄O 2.

DI-PHENYL-DI-TOLYL-(ETIVLEND GUIDE.

Di-PHENYL-DI-p-TOLYL-ETHYLENE OXIDE.
Phenyl-tolyl-(3)-pinacolin

C.H. CO.OPh(C.H.), [137°]. Formed by the action of AcCl on phenyl tolyl-(a)-pinacolin or on phenyl tolyl-pinacone (Zincke a. Thörner, B. 10, 1477; 11, 65, 1396; A. 189, 110). Prepared by boiling phenyl p-tolyl ketone with alcohol, HClAq, and zinc. Small dimetric tables, sl. sol.

cold alcohol. On heating with soda-lime at 300°

tyields phenyl-di-tolyl-methane.

PHENYL-TOLYL-PINACONE C₂H₂₀O₂ i.e.
C,H,,CPh(OH).CPh(OH),O,H,. [165²]. Formed
by treating an alcoholic solution of phenyl ptolyl ketone with zinc and B₂SO₄ (Zincke a.
Thörner, B. 10, 1476). Minute needles (from alcohol). Decomposed by fusion and by boiling alcoholic potash into phenyl tolyl ketone and phenyl-tolyl-carbinol. Converted into phenyltolyl-(8)-pinacolin by heating with dilute H2SO, at 160°, with HOAc at 190°, with Accl, or with HClAq. Alcoholic HCl in the cold forms HCIAq. Alcoholic Horan phenyl-tolyl-(a)-pinacolin. PHENYL-TOLYL-PROPANE PHENYL-TOLYL-PROPANE

CH, CHPh.CH, C, H, Me. The o- (817°), m. (312°), and p- (803°) compounds are formed by the action of conc. H₂SO₄ on a mixture of styrene and o-, m-, and p-xylene respectively (Kraemer, Spilker, miscible with alcohol and ether.
PHENYL-TOLYL-PROPIONIC ACID

CH.Ph.CH(C,H,Me).CO.H. o. [95.5°], m. [80°], p. [105°]. Formed from the corresponding p- [105°]. Formed from the corresponding nitriles, which are got from the tolyl-acetonitriles by treatment with NaOEt and benzyl chloride (Päpcke, B. 21, 1331). The o-nitrile is an oil (\$40°.858°); the m-nitrile [58°] (350°.
\$60°), and the p-nitrile [79°] are crystalline.

Di-phenyl-p-tolyl-prophonic acid. Nitrile

CH,Ph.CPh(C,H,Me).CN. [121°]. Formed from phenyl-pticyl-acetonitrile, NaOEt, and benzyl chloride (Neure, A. 250, 150). Needles. DI-PHENYL-TOLYL-PYRROLE C, H, N i.e.

NC,H, CPh:CH. The o- [115°] (above 300°) and p- [203°] sompounds are formed by distilling the corresponding carboxylic acids with lime (Baumann, B. 20, 1492; Paal a. Braikoff, 22,

3089). Both crystallise in white needles.
DI-PHENYL-TOLYL-PYRROLE CARBOXY-LIC ACID N(C,H₇) CPh:C.CO₂H. The o-acid [227°] and its p-isomeride [206°] are got by saponification of the ethers, which melt at 135° and 145° respectively, and are formed by boiling the corresponding toluidine with phenacylbenzoyl-acetic ether CH2Bz.CHBz.CO2Et and HOAc (Paal a. Braikoff, B. 22, 3088). Both acids are crystalline and al. sol. ether.

Di-phenyl.p-tolyl.pytrole dicarboxylic acid N(C,H,) C(C,H,CO,H):CH [253°]. Formed by heating C,H,(CO,C,H,CO,H); with p-toluidine on a water-bath (Baumann, B. 20, 1489). Yellowish needles, v. sol. alcohol and CS, PHENYL P.TOLYL SULPHIDE Ph.S.C,H, An oil yet by the setting of NeSPh on prilars.

An oil got by the action of NaSPh on p-diazo-

toluene chloride (Ziegler, B. 23, 2471) Phenyl p tolyl disulphide P Thenyl p tolyl disulphide Ph.S.C.H.,
Formed by adding Lr to an ethereal solution of
PhSH and C.H.SH. Got also, together with Ph.S., by heating toluene p-sulphinic acid with PhSH (Otto a. Rössing, B. 19, 3133). Thick oil, insol. water, scarcely volatile with steam.

PHENYL p.TOLYL SULPHONE C, H, SO, i.e. C, H, SO, C, H, Me. [125°]. S. (alcohol) 1.62 at 20°. Formed by the action of P,O, on a mixture of toluenc and benzene sulphonic acid, or of benzene and toluene p-sulphonic acid (Michael a. Adair, B. 11, 116). Formed also from benzene sulphonic chloride, toluene, and AlCl, (Beckurts a. Otto, B. 11, 2068). Prisms or tablets, PHENYL-o-TOLYL-SEMI-THIOCARBAZIDE

C, H, N, S i.e. NHPh.CS.NH.NH.C, H, Me. [146°]. Formed from phenyl-thiocarbimide and o-tolyl-hydrazine (A. E. Dixon, C. J. 57, 260). Pearly prisms, v. 8l. sol. water, v. sol. hot-slochol. Isomeride C.H.MeNH.CS.NH.NHPh. [163°].

Formed from o-tolyl-thiocarbimide and phenyl

hydrazine. Vitreous prisms v. sl. sol. water. PHENYL o-TOLYL-THIO-UREA C14H14N28 i.e. NHPh.CS.NHC, H, Me. [140°]. Formed from o-tolyl-thiocarbimide and aniline (Staats, B. 13, 157) and by passing H.S into a boiling solution of phenyl-tolyl-cyanamide NPh:C:NC,H, in dry benzene (Huhn, B. 19, 2411). Long needles, sl. sol. water. Boiling HClAq (34 p.c.) splits it up into aniline, o-toluidine, phenyl-thiocarbimide, and o-tolyl-thiocarbimide (Mainzer, B. 15, 1419). HgO, added to its solution in boiling benzene, forms phenyl-tolyl-cyanamide.

Phenyl-p-tolyl-thio-urea NHPh.CS.NHC,H,Me. [1 NHPh.CS.NHC, H, Me. [\$37°] (S.); [141°] (F. a. W.). Formed from p-tolyl-thiocarbimide and applies (S.) and from the p-tolyl-thiocarbimide and applies (S.) and aniline (S.), and from phenyl-p-tolyl-cyan-amide and H₂S (H.). Plates, sl. sol. water. Split up by HClAq in the same way as the o- isomeride (M.), and decomposed by HgO in like manner. COCl, passed into its solution in toluene forms NPh:O (N(C,H,)) CO [89°], crystallising in white needles (Freund a. Wolf, B. 25, 1466).

white needies [recuise a. 105.]

Tetra-w-phenyl-dio-tolyl-thio-tres

C₂₀H₂N₂N₂S i.e. (CHPh₂C₂H₄NH)₂CS. [123°].

Formed from CHPh₂C₂H₄NH₂ and CS₂ (Fischer and CS₂) a. Franckel, A. 241, 368). White needles, insol. cold alcohol.

References. NITRO- and OXY- PHENYL-TOLYL-THIO-UREA.

PHENYL - p - TOLYL - THTO - UREA-w-CARB-

OXYLIC ACID. Nitrile NHPh.CS.NH.C.H., CH., CN. [141°]. by warming phenyl-thiocarbimide with amidophenyl-acetonitrile (Freund a. Immerwahr, B. With furfuraldehyde it forms 23, 2856). NHPh.CS.NH.C.H., CCy:CH.C.H., O [160°] crystallising from alcohol.

PHENYL-O-TOLYL-UREA C1.H1.N2O i.e. NHPh.CO.NHC, H, Me. [212°]. Formed by boiling NPh:C:NC, H, with dilute alcohol (Huhn,

B. 19, 2410). Slender needles.

Phenyl-m-tolyl-urea. [165°]. Formed from phenyl cyanate and m-toluidine in ether

(Buchka a. Schachtebeck, B. 22, 840). Needles.
Phenyl-p-tolyl-urea. [2112] (H.); [2182]
(Freund a. Wolf, B. 25, 1467). Formed by boiling phenyl-p-tolyl-cyanamide with dilute alcohol (Huhn, B. 19, 2408).

Phenyl-di-p-tolyl-urea C, H, N,Oe Formed from (C₆H,Me),NCOCl and aniline (Hammerich, B. 25, 1821). Needles, sol. alcohol.

Di-phenyl-p-tolyl-urea NPh2.CO.NHC.H,. [130°]. Formed from NPh. COCl and p-toluidine (Michler, B. 9, 713). Needles.

References. - OXY-PHENYL-TOLYL-TIREA

(B)-PHENYL-UMBELLIFERONE C15H10O, i.e. $\begin{bmatrix} 4_2^1 \end{bmatrix}$ C_4 H_2 OH CPh:CH O-CO[244°]. Prepared by the action of H,SO, on a mixture of benzoylacetic ether and resorcin (Pechmann a. Duisberg, B, 16, 2126). Plates (from dilute alcohol).
PHENYL - URAMIDO - ACETO - NITRILE

C.H..CH(CN).NH.CO.NH, Phonyl-aceto-Formed by heating equimolecular quantities (Pinner a. Lifschütz, B. 20, 2355). Prisms. V. sol. alcohol, m. sol. hot water. By boiling with dilute HCl it is converted into di-oxyphenyl-glyoxaline CHPh.N C.OH.

PHENYL-URAMIDO-BENZOIC ACID v. vol. i. p. 157.

PHENYL - a - URAMIDO - CROTO - NITRILE C.H., CH:CH.C(CN)H.NH.CO.NH, Phenyl-crofomitrile-urea. [160° with decomposition]. Prepared by heating equivalent quantities of cinnamical dehyde-cyanhydrin and urea to 96° for several hours; the yield is 40 p.c. of the cyanhydrin (Pinner a. Lifschütz, B. 20, 2353). Needles.

M. sol. hot alcohol. By boiling with dilute HCl it is converted into di-oxy-styryl-glyoxaline CO NH.CH.CH:CHPh

PHENYL - URAMIDO - PHENYL - ACETIC NHPh.CO.NH.CHPh.CO.H. ACID Formed by the action of potash on di-phenyl-thiohydantoin (Kossel, B. 24, 4153). Sol. water.

Ethyl ether EtA', [165°]. Formed from phenyl-amido-acetic ether and phenyl cyanate

(K.). Crystalline powder, sol. hot alcohol. PHENYL-UKAMIDO-PROPIONIS C₁₀H₁₂N₂O₃ i.e. C₅H₁NH.CO.NH.CH₂.CH₂CO₂H₄. [172°]. Formed by heating β-amido-propionic 172. Formed by neating stando-propione acid with phenyl-urea at 140° (Hoogewerff a. var borp, R. T. C. 9, 49). Tablets and needles, m. sol. cold alcohol. AcCl forms C₁₈H₁₀N₁O₂

NPh < NH.CO NPh. [264°]. Formed heating plienyl semicarbazide at 160° (Pinner, B. 21, 2329) or phenyl-carbazic other at 240° (Heller, A. 263, 282). White needles, v. sol. warm HOAc. Yields the acetyl derivatives the other C, II, EtN, O, [137].

PHENYL-URAZOLE v. DI-OXY-PHENYL-TRI-

PHENYL-UREA C.H. N.O i.e. NHPh.CO.NH,. [147°]. Formation.—1. By passing cyanic acid vapour into cooled aniline or from aniline sulphate and potassium cyanate (Hofmann, A. 53, 57; 57, 265; 70, 130; 74, 14; Weith, B. 9, 810). 2. From aniline and moist cyanogen chloride.—3. From phenyl cyanate and NH₃.—4. From mercuric fulminate and aniline (Steiner, B. 8, 518). • 5. From benzamidoxim, NaOH, and benzene sulphonic chloride (Pinnow, B. 24, 4171).

Properties. - Monoclinic needles, v. sol. alcohol and boiling water, sol. ether. Decomposed at 150° into s-di-phenyl-urea, CO2, and NH2

Reactions .- 1. Conc. KOHAq yields aniline, NH₂, and CO₂ - 2. Baryta-water yields phenylbiguanide (Emich, M. 12, 16).—8. Assiste at 190° forms s-di-phenyl-urea .-- 4. Fuming sul-and phenyl-parabanic acid.

Acetyl derivative NHPh.CO.NHAc. [183°]. Needles (McCreath, B. 8, 1181; Kühn, NHPh.CO.NHAc. B. 17, 2880; Pinnow, B. 24, 4171).

Propionyl derivative. [137°]. Prisms. Benzoyl derivative NHPh.CO.NHBz.

[199] Silky needles, v. sol. alcohol.
s-Di-phenyl-urea C₁, H₁₂N,O, i.e. CO(NHPh),
Mol. w. 212. Carbanilide. [235°]. (260°).

Formation .- 1. From aniline and phenylcyanate (Hofmann, A. 57, 266; 74, 15).—2. From aniline and COCl. (Hofmann, A. 70, 488; Hentschel, J. pr. [2] 27, 499).—3. By heating diphenyl-thio-ures with alcoholic potash.—4. By. distilling phenyl-urea (H.; Pinnow, B. 24, 4172). 5. By dry distillation of aniline oxalate (Hofmann, Pr. 15, 335).—6. By heating urea (1 pt.) with aniline (3 pts.) at 160° (Baeyer, A. 131, 251) or phenyl-ures (1 mol.) with aniline (1 mol.) at

185° (Weith, B. 9, 821).—7. Together with NH,, benzamide, and benzanilide, by heating dibenzoyl-ures with aniline at 180° (Holleman, 80. T. C. 10, 72).—8. By the action of an ethereal solution of ClCO₂COl₂ on aniline (Hentschel, J. pr. [2] 36, 310).—9. From NHPh.CO₂Et and aniline at 160° or NaOPh at 220°.—10. From CO(OPh). and aniline at 150° 180° (Eckenroth, B. 18, 516). 11. From C(OEt), and aniline at 280° (Bender, B. 13, 699).-12. By heating carbamic ether with aniline (3 mols.) at 180°-185° (Smolka, M. 11, 200).—13. From benzamidine hydrochloride, phenyl cyanate, and NaOHAq (Pinner, B. 22, 1607).

Properties.—Prisms (from alcohol), v. al. sol. water, v. sol. alcohol and other. May be distribed.

Reactions.—1. Conc. H.SO, forms CO, and

C.H.(NH2)SO2H.-2. Alcoholic NH3 forms urea and aniline (Claus, B. 9, 693) .- 3. PCl, forms phenyl cyanate (Weith, B. 9, 810). QCO_CCl₃ also forms phenyl cyanate on heating.—4. P.O. forms phenyl cyanate and aniline.—5. Pry NaOEt at 220° forms aniline and tri-phenyl-guanidine.—6. CICO.CO.Et forms di-phenylparabanic acid.

Acetyl derivative NHPh.NPhAc. [115°].

Jaminæ (from water) (McCreath, B. 8, 1181).

4-Di-phenyl-urea NPh, CO.NII. [189°].

Formed from NPh, COCI [85°] and alcoholic NH, at 100° (Michler, B. 8, 1665; 9, 396, 715). Needles. Gives a blue colour with H₂SO₄. Split up by distillation into evanicacid and diphenyl-

Tri-phenyl-ures NPh2.CO.NHPh. Formed by heating a solution of NPh. COCL dissolved in chloroform, with aniline at 130° (Michler, B. 9, 396, 715). White needles. Resolved by heat into diphenylamine and phenyl cyanate.

Tetra-phenyl-urea CO(NPh₂)₂ [183°]. Formed by heating NPh₂-COCl with NPh₂H and zinc dust (Michler, B. 12, 1166). Got also from diphenylamine and COCl, (Girard a. Willm, Bl. [2] 25, 248). Resolved by HClAq at 250° into diphenylamine and CO...

References. — Amido-, Bromo-, Chloro-, Chloro-, Nitro- and Oxy- Phenyllurea.

NHPh.Co.NH.C.H.CO.H. [270°]. Formed by heating m-amido benzoic acid with phenyl cyanate at 100° (Kühn, B. 17, 2882). Prisms, sol. alcohol, sl. sol. ether.

Di-phenyl-urea di-m-carboxylic acid C₁₅H₁₂N₂O₅, i.e. CO(C₆H₁.NH.CO₂H)₂.

Formation .- 1. By heating m-uramido-benzoic acid (Griess, Z. 1868, 650; B. 9, 796). - 2. By heating a mixture of m-uramido-benzoic acid with m-amido-benzoic acid at 175° (Traube, B. 15, 2122).-3. From m-amido-benzoic acid and. COCl₂ (Sarauw, B. 15, 44).— 4. By boiling CS(C₄H_a,NH.CO₄H)₂ with HgO and KOHAq (Griess, A. 172, 169).—5. By heating urea with m-amido-benzoic acid at 130° (T.).

Properties. - Minute needles, almost insol. water, alcohol, and ether.

Estata.—Bah" 3aq.—Pbh".—Ag.h".

Ethyl ether Et.h". [162°]. Needles.

Amide CO(C.H., NH.CO.NH.)... Got by heating urea with m-amido-benzamide at 140° (Schiff, A. 232, 140). White powder, insol. water, de-composing above 270°.

Di-phenyl-ures di-p-carboxylic acid. Formed when urea is heated with ρ -amido-benzoic acid (Griess, J. pr. [2] 5, 370). Small needles.—BaA". TETRA - PHENYL - UVINONE $C_{11}H_{20}O_{1}$.

Formed in small quantity in the preparation of di-phenyl-furfurane by heating di-phenyl-fur-furane dicarboxylic acid (Perkin a. Schlosser, C. J. 57, 956). Thin yellow needles, not melting at 280°. H,SO, forms a dark-green solution with brick-red fluorescence.

DI-PHENYL-VALERAMIDINE C17H20N2, i.e. C,H,,C(NPh).NHPh. [111°]. Formed by heating isovaleric acid with aniline and PCl, at 150° (Hofmann, J. 1865, 416). Crystalline, nearly insol. water.

B-PHENYL-n-VALERIC ACID

CHPhPr.CO.H. [52°]. Formed by heating its nitrile with FECIAq at 185° (Rossolymo, B. 22, 1235). Needles.

Nitrile CHPhPr.CN. (261°). Formed from

phenyl-acetonitrile, PrI, and NaOH. Oil.
β-Phenyl-iso-valeric acid C₁₁H₁₁O₂ CH,Ph.CHEt.CO,H. (272°). Formed by reduction of phenyl-angelic acid with sodium-amalgam (Baeyer a. Jackson, B. 13, 118). Formed also by heating benzyl-ethyl-acetoacetic ether with conc. KOHAq (Anschütz, A. 261, 306). Oil.-AgA'.

Chloride (c. 147° at 24 mm.). Oil. A mide ChiHis NO. [89°]. Monoclinic A mide $O_{17}H_{19}NO$. [89°]. Mon-crystals; $a;b:c=817:1:1\cdot189$; $\beta=70^{\circ}28'$.

γ-Phenyl-valeric acid

CH_Ph.CHMe.CH_CO_H. (176.5° at 15 mm.). Got by potash-fusion from 'diethyl carbo-benzonic' acid, which is a product of the action of alcoholic potash on deoxybenzoin (Anschütz, A. 261, 302). Oil, yielding benzoic acid on oxidation.

Ethyl ether C₁₃H₁₈O₃. (146° at 15 mm.). Chloride C₁₁H₁₈OCl. (131° at 11 mm.). Anilide C₁₇H₁₈NO. [102°]. Trimetrio Anilie C, H, NO.

peedles; a:b:c = 6851: 608. δ -Phenyl-valeric acid

CII, Ph.CH., CH., CH., CO., H. [659°]. Formed by reducing CHPh:CH.CH.CH.CH.CO.H (Baeyer a. Jackson, B. 13, 122). Leatlets, sl. sol. water.

Bensyl ether. (330°-340°). S.G. 172 1.027. Got by heating benzyl butyrate with Na at 130° (Conrrd a. Hodgkinson, A. 193, 318).

Isomeride v. BENZYL-ISOBUTYRIC ACID.

Reference.—Anido-, Di-Bromo-, Di-Bromo-Amido-, Nitro- and Oxy- Phenyl-Valeric acids.

PHENYL-VINYL- v. STYRYL-.

DI-PHENYL-VINYL-DIAMINE C, H, N, i.e. NHPh.CH, CH:NPh. [105°]. Formed by heating CH,Cl,CH:NPh with aniline (Berlinerblau, M. 8, 187). Sol. alcohol and ether.

PHENYL VINYL KETONE CARBOXYLIC ACID v. BENZOYL-ACRYLIC ACID.

DI-PHENYL-VINYL NITRITE $C_{i,i}H_{i,i}^{*}NO_{2}$ i.e. CPh.:CH.NO. [87°]. Formed by gradually adding HNO. (1 pt.) to a hot solution of di-phenyl-ethane (1 pt.) in HOAc (10 pts.) (Anschütz a. Romig, A. 233, 327). Needles, v. sol. alcoffol and ether.

* TRI - PHENYL VINYL TRISULPHONE C,H,SO,CH,CH(SO,C,H,)2. [86°]. Formed by oxidising the product of the action of NaSPh on CHCl2.CH2Cl (Otto, B. 24, 1835). Crystalline.

PHENYL-XYLENE v. DI-METHYL-PIPHENYL and RHENYL-TOLYL-METHANE.

PHENYL-XYLIDINE C₁₄H₁₅N i.s. C₄H₃M_{3r}, NHPh. [52°]. (173° at 15 mm.). Formed by heating xylidine with aniline hydrochloride (Girard a. Vogt, Bi. [2] 18, 67). Sol. alcohol.

PHENYL-0-XYLYL-CARBINOL C₁₃H₁₀O i.s. C₂H₁,CH(OH),C₂H₃Me₂[1:3:4]? [68°]. (336°1.V.) at 744 mm. V.D. 107·7 (for 106). Formed from the ketone, KOH, and zinc-dust (Elbs, J. pr. [2] 35, 469). White radiating needles (from alcohol). Somewhat decomposed by distillation.

Phenyl.m. xylyl.carbinol C_aH_..CH(OH).C.H_aMo_s [1:2:4]? [57°]. (331° i.V.) at 744 mm. V.D. 102·7 (for 100). Formed from the corresponding ketone by reduction (Elbs,

J. pr. [2] 35, 472). Phenyl-p-xylyl-carbinol

C_sH_s.CH(OH).C_sH_sMe_s[1:2:5]. [88°]. Formed from the ketone, KOH, and zinge-dust (Elbs). Prisms (from alcohol); v. sl. sol. water, m. sol. HOAc, v. e. sol. alcohol and ether.

PHENYL-p-XYLYL-p-CYMYL-METHANE [2:5:1] Me₂C₆H₃.CHPh.C₆H₃MePr[1:2:5]. Formed from phenyl-p-cymyl-carbinol, p-xylene, and P.O. (Elbs, J. pr. [2] 35, 498). Oil.

DI - PHENYL - o - XYLYLENE - DIAMINE C20 H20 N2 i.e. C8 H4 (CH2.NHPh)2. [172°]. Formed by boiling di-ω-bromo-o-xylene with an alcoholic solution of aniline (Lesser, B. 17, 1825). Small plates (from alcohol).

PHENYL o-XYLYL KETONE C15H14O i.e. C.H.,CO.C.,H.,Me., [1:3:4]? [48°]. (310°. i.V.) at 741 mm. V.D. 102-2 (for 105). Formed from BzCl, o-xylene, and AlCl.; the yield is 80 p.c. (Elbs, J. pr. [2] 35, 467). Groups of snowy needles (from alcohol). Insol. water, sl. sol. cold HOÀc, v. sol. alcohol.

Phenyl m-xylyl ketone C₆H₃.CO.C₆H₃Mc₂ [1:2:4]. (321° i.V.) at 744 mm. V.D. 102·3 (for 105). From m-xylen, BzCl, and AlCl, (Söllscher, B. 15, 1682; Elbs, J. pr. [2] 35, 469). Oil. Partly converted by long boiling into (B. 2)-methylanthraquinone. In presence of a little of the corresponding phenyl - xylyl - carbinol, (B. 2)methyl-anthracene is formed.

anti-Oxim CsHy.C.CsHs. [126°]. verted by PCl, into C, H, CO.NHPh (Smith, B. 24, 4048). Yields an acetyl derivative [91°], crystallising in flat prisms.

syn-Oxim C_nH_y.C.C_sH_s. [152°]. Formed, as well as the preceding body, by the action of an alcoholic solution of hydroxylamine on the ketone. PCl, at -20° forms C.H., CO.NHC, II,

Yields an acetyl derivative [103°

(Elbs, B. 17, 2847; J. pr. [2] 35, 472); the yield is 65 p.c. Transparent prisms (from alcohol), ir sol. water, m. sol. HOAc, v. e. sol. ether and al-cohol. Very slightly volatile with steam. Yields

methyl-anthracene when boiled for a long time.

Reaction.—10 H.SO, has no action in the cold, but on warming HOBz is aplit off...

2. H.S.O., forms a disulphonic acid
C.H.Me..CO.C.H.(SO.H)... whose salt BaA"2aq
is v. e. sol. water...—3. HNO. (S.G. 1.15) at 180°
forms benzophenone dicarboxylis acid C.H., CO.C.H., (CO.H), [1:2:5].

PHENYL-O-XYLYL-KETONE or CARB OXYLIC ACID

[4:3:1] C_aH,Me,CO.C,H,CO₂H [2:1]. $Xulene \bullet$ phthaloglic acid. [162°]. Formed by the action of AlCl, on a mixture of phthalic anhydride and o xylene (F. Meyer, B. 15, 636). Minute prisms (containing aq). Yields benzoic and (4,3,1)-di-

methyl-benzoic acids when fused with potash.

Phenyl-m-xylyl-ketone o-carboxylic acid [4:2:1] C.H.Me., CO.C.H., CO.H. Formed in like manner from m-xylene (M.). Needles, sl. sol.

water, sol. alcolol.

Phenyl-p-xylyl-ketone o-carboxylic acid [5:2:1] C₀H₃Me₂.CO.C₀H₄.CO₂H [1:2]. Formed in like manner from p-xylene. Amorphous solid,

insol water, sol. alcohol and benzene.

henyl-m-xylyl-ketone (a)-carboxylic acid
C_bH₃CO.C_oU.Me_a.CO_.H [4:5:3:1]. [160°]. Formed, together with the following isomeride, by oxidising benzoyl-mesitylene with chromic acid mixture (Louise, Bl. [2] 44, 418; A. Ch. [6] (1, 218). Needles, v. sol. other, insol. cold water.—BaA', 2aq.—MgA', 6aq.—AgA': needles.

Phenyl-m-xylyl-ketone (\$\beta\$)-carboxylic acid

C₈H₄.CO.C₄H₂Me₂.CO₂H[2:5:3:1]. [185°]. Formed as above. The Mg salt is more soluble than that of the isomeric acid. Efflorescent needles, v. sl. sol. hot water. Converted by P.O. into di-methyl-anthraquinone [158°]. - AgA': needles.

Phenyl-xylvl-ketone dicarboxylic C.H. CO.C. HMe₂(CO₂H)₂. Bensoyl-cumidic acid. [85°]. Formed by oxidation of phenyl duryl ketone (F. Meyer a. Ador, J. 1879, 562). Melts

Retono (F. Meyer a. Ador, J. 1879, 562). Metts at 86°, becomes solid, and melts again at 173°. — BaA'₂ 2° aq: long silky needles. PHENYL - DI · p · XYLYL - METHANE C. H. Cll(C. H. Mc.)₂ [1:2:5]₂. [93°]. (above 360°). From phenyl p-xylyl carbinol and p-xylene (Elbs, J. pr. [2] 35, 476). Or from di-p-xylyl carbinol, benzene, and P.O. Prisms (from ligroin). Its solutions show blue fluorescence. ligroin). Its solutions show blue fluorescence.

Di-phenyl-o-xylyl-methane C₂₄H₂₀ i.e. (C₆H₃)CH.C₆H₃Me₂(1:3:4]. [68:5°]. (above 360°). Formed from di-phenyl-carbinol, o-xylene, and P.O. Hlemilian, B. 19, 3070). Needles, v. sol. alcohol and ether.

Di-phenyl-m-xylyl-methane

C_aH_aCH_aC_bH_aMe_a[1:2:4] [61:5°] (above 860°). Formed by boiling di-phenyl-carbinol with m-xylene and P₂O₃ (Hemilian, B. 19, 3061). Prisms, v. sol. alcohol and ether. Oxidised by chromic acid mixture to methyl-di-phenyl-phthalide and di-phenyl-phthalide carboxylic

Di-phenyl-p-xylyl-methane. [92°]. (above 360°). Formed by digesting di-phenyl-carbinol with p-xylene and P.O. (Hemilian, B. 16, 2360; Bt. [2] 34, 326; Petrieff, Bt. [2] 41, 316). Monoclinic crystals, v. sol. alcohol and ether. Oxidised by chromic acid mixture to di-phenylmethyl-phthalide [170°], di-phenyl-tolyl-carbinol m-carboxylic acid [c. 253"] and di-phenyl-phthalide carboxylic a..d [245°].

Reference.-NITHO-DI-AMIDO-PHENYL-DI-XYLYL-

PHENYL-DI-XYLYL-METHANE o-CARB-OXYLIC ACID [4:2:1] C.H.Me.CH..C.H.,CO.H. [158°]. Formed by reducing phenyl-m-xylyl-ketone carboxylic acid with zinc-dust and NH,Aq (Gresly, A. 234, 237). Small needles (from alcohol).—BaA', aq: plates (from dilute alcohol). - PHENYL-P.XYLYL-(8).PINACOLIN C₂₀H₂₀O
6.8. C.H. C(C.H.Me₂)₂CO.C.H., [146°]. Formed
by the action of ziac and HClAq on phenyl
p.xylyl ketone (Elbs, J. pr. [2] 35, 477). Clumps
of prisms (from ligroin), nf. sol. alcohol and ether.
Soda-lime at 320° splits it up into benzoic
acid and phenyl-di-xylyl-methane.
PHENYL-XYLYL-PROPANE C., H₂₀ 6.6.

PHENYL-XYLYI-PROPANE O, H., e.s. C, H., CHMc. CHL, C, H., Me., (324°). Formed from ψ -cumene, styrene, and conc. H., SO₄ (Kraemer, Spilker a. Ebenhardt, A. 23, 3273).

PHENYL-XYLYL-PROPIONIC ACID
C,H,Me,-CHPh.CH,-CO,H. Formed from cinnamic acid, m-xylene, and H,SO, (Liebermann
a, Hartmann, B. 25, 959). Amorphous, v. sol.
warm benzene. When allocinnamic acid is used
it is accompanied by another, acid [220°].
DI-PHENYL-XYLYL-PYRROLE CARB-

DI-PHENYL-XYLYL-PYRROLE CARB-OXYLIC ACID O.H.N CPh:C.CO.H. [254°].

Formed by saponifying its oly ether which is got from phenacyl-benzoyl-acctic ether and (4.2,1)-m-xylidine (Pasl a. Braikoff, B. 22, 3000).

Small needles, m. sol. hot alcohol and benzene.

PHENYL-XYLYL SULPHONE C.,II.,SO., i.e.

C.H., SO., C.H.Me., [80°]. Formed from benzene sulphonic chloride, m-xylene, and AlCl. (Beckurts a. Otto, B. 11, 2063). Vellowish needles.

THENYL m.XYLYL-UREA C₁₅H₁₈N₁O i.e.

THENYL m-XYLYL-UREA C₁₅H₁₆N₁O i.s. C₅H₅NH.CO.NHPh. [131°]. Formed by mixing m-xylidine with phenyl cyanate (Brömme, B. 21, 2703). White matted needles, sol. alcohol. PHENYTHRONIC ACID 2. PHENYL-METHYL-

PHENYTHRONIC ACID 2. PHENYL-METHYL-FURFURANE DIGARBOXYLIG ACID.

PHILLYRIN C₂,H₂,O₁, 1½aq. [160°]. S. ·08 at 9°; S. (alcohol) 2·5 at 9°. A glucoside in the bark of Phillyrea latifolia (Bertagnini, A. 92, 109; 118, 124). Crystalline, insol. ether. Split up by dilute acids into glucose and crystalline phillyenin C₂,H₂,O₄, v. sol. ether. A glucoside C₂,H₂,O₁ ([184°]; S. ·05 in the cold, 12·5 at 100°) in Olea fragrams is perhaps identical with phillyrin. It is split up by acids into glucose and C. H₂,O₁ (70°) (Eykman, R. T. G. 5. 127).

C₂₈H₂₂O₂ [70°] (Eykman, R. T. C. 5, 127).

PHLEIN C₂₈H₃₂O₃, [215°]. S.G. 1.48. S.
26 at 10°. [a]₂ = -48·5. Occurs in the bulbs of cat's-tail grass (Phieum pratense) and in the roots of Baldigera arundinacea (Ekstrand a. Johnnike., B. 20, 3310; 21, 597). Carbohydrate resembling starch, but not coloured blue by iodine. Reduces AgNO₃, but not Fehling's solution.

PHLOBAPHENE C₁₈H₁₈O₁₁. Named from φλοιδε, bark, and βαφή, colour. Occurs in oak bark, and formed by boiling quercitannic acid with dilute acids (Hofstetter, A. 51, 63; Grabowski, A. 145, 8; Oser, J. 1876, 903; Böttinger, A. 202, 270; 240, 338). Reddish-brown powder, insol. water, ether, and cold alcohol. Alkalis form a reddish-brown solution, which absorbs oxygen from the air. Turned black by FeCl., Potash-fusion yields protocate-buis oxid (Procter, C. J. 36, 979). Yields C₃;H₁₉Ac,O₁, C₃₈H₁₉B₂,O₁₁, and C₃₈H₃₈K₁O₁₁, which is insol. alcohol, v. sol. water. Bromine yields C₃;H₁₉Br₁₆O₁, and C₃₈H₃₂Br₄O₁, which forms C₃₈H₁₈Br₄O₁, and C₃₈H₃₂Br₄O₁, which forms C₃₈H₁₈Br₄O₁, and C₃₈H₃₂Br₄O₁, thick forms C₃₈H₁₈Br₄O₁, and C₃₈H₃₂Br₄O₁, thick forms C₃₈H₁₈Br₄O₁, and C₃₈H₃₀Br₄O₁. Seembling phlobaphene occurs in hops (Etti, A. 180, 223; D. P. J. 228, 354).

PHLOGISTIC THEORY v. Combustion, vol. ii. pp. 241-2.

PHLORANIES C.H., NO., 4.c.

C.H., (OH), (NH.). Amido-resorcin? Formed by passing NH, over phloroglucin (Hlasiwetz a. Pfaundler, A. 119, 202). Thin plates (from water), al. sol. cold water, v. sol. alcohol, insol.

water), sl. sol. cold water, v. sol. atconol, misol.
ether. Turns browne in air. Decomposed by
alkalis. Its solutions are not coloured by FeCl.,
—B'HCl.—B'₂H₂SO, 2aq:long yellowish needles.
PHLOREIN C₁₈H₁₁NO₂, Formed by passing

PHLOREIN C₁₂H₁₁NO₂. Formed by passing nitrous acid gas into an ethereal solution of phloroglucin (4 g.) containing HNO₂ (4 c.c. of S.G. 1°25) (Benedikt, B† 7, 445; A. 178, 93). Lustrous dark-green powder, insol. water, v. sol. alcohol and ether, forming a dark-brown solution. Alkalis form a purple solution. Yields phloroglucin when fused with potash. Zinc and dilute H₂SO₄ form a colourless body, re-oxidised to phlorein by air.

PHLORETIC ACID v. p-OXY-a-PHENYL-PRO-

PHLORETIC ACID v. p-OXY-a-PHENYL-PRO-PIONIC ACID. It yields a crystalline di-bromoderivative (Fllasiwetz, A. 102, 145).

derivative (Hasiwetz, A. 102, 145).

PHLORETIN C₁₅H₁₄O₅. [255°]. Formed by boiling phlorizin or glyoyphyllin with dilute acids (Stas, A. 30, 200; G. Roser, A. 74, 178; Hlasiwetz, A. 96, 118; Schiff, A. 156, 2; 172, 357; 229, 374; Rennie, C. J. 49, 860). Small lamine, with sweet taste, v. sl. sol. hot water and ether, v. e. sol. alcohol. Inactive to light. Bromine forms C₁₅H₁₆Br₁O₅ (295°-210°) (Schmidt a. Hesse, A. 119, 103). Alkaline solutions absorb oxygen and turn orange in air; boiling cone. KOHAq splits it up into phloretic acid and phloroglucin. Aniline at 170° forms C₁₈H₁₈NO₄, a scarlet powder. AcCl gives amorphous C.,H₁₈NO₄, a scarlet powder.

Salts. $-C_{15}H_{11}(NH_{_3})_2$: amorphous. Gives off $NH_{_3}$ in air. $-C_{29}H_{18}Nb_2$ 0; and $-C_{15}H_{12}Aa_2$ 0.

winstable pp.

PHLOBIZIN C₂₁H₁₁O₁₀ 2nq. Named from φλοιόs, bark, and φίζα, root. [109°] (when anhydrous). S.G. ½ 1·43. S.·1 in the cold. [a]₁ = -49 at 15°. Occurs in the root-bark of the apple, pear, plum, and cherry tree, from which it may be extracted by dilute alcohol (Stas a. De Koninck, A. 15, 75; 30, 193; A. Ch. [2] 69, 367; Mulder, Rev. Scient. 3, 50; Roser, A. 74, 178; Strecker, A. 74, 184; Rennie, C. J. 51, 635). Silky needles with slightly bitter taste, sl. sol, cold water, v. e. sol. hot water and alcohol, insol. ether. Melts at 109°, becomes solid, and melts again at 171°. Lævogyrate. Decomposed by dilute acids into glucose and phloretin. Gives pps. with baryta and McOH, with time-water, and with lead subacetate. Air and ammonia form reddish-brown amorphous phlorize n C₂₁H₂₀N₂O₁₂. Gives a violet colour on boiling with ZnSO₄ and KNO₂ (Nickel, Fr. 28, 248). FeCl, gives a brownish-red colour. Aniline at 180° forms $C_{s_0}H_{s_1}N_2O_s$, a yellow powder, yielding a mono- and a tri- acetyl derivative.

 $\begin{array}{cccc} A \ cotyl & derivatives & O_{21}H_{22}AcO_{10} \ 2aq: \\ needles & (from water). & & C_{21}H_{21}Ac_2O_{12}. & & \\ C_{21}H_{12}Ac_2O_{12}aq: & amorphous solid. & & \\ \end{array}$

Tri. bensoyl derivative. Powder.

Isophlorisin C₂₁H₂₂O₁₉. [105°]. Occurs in the leaves of the apple-tree (Rochleder, Z. [2] 4, 741). Silvery needles. Its ammoniacal solution turns brown in air. Its solution is ppd. by lead subacetate. Dilute H₂SO₄ splits it up into glucose and isophloretin C₁₂H₁O₃, which is v. sol. ether, and yields phloroglucin when heated with cone. KOHAq.

philorobrowine C.Br.HO. [182°]. Formed by the action of excess of bromine on a very dilute aqueous solution of phloroglucin (Benedikt, 4. 189, 165; C. J. 34, 499). Dimetric prisms; a: b=1:1-2. Insol. water. Not attacked by potash or HNO,. Warm alcohol decomposes it, forming penta-bromo-acetone [76°]. NH,Aq ferms CBr,H and C,Br,H,N₂ crystallising from water in colour-less lamins [124°].

PHLOROGLUCIN C.H.O. i.e. C.H.(OH). [1:3:5]. Mol. w. 126. [219°] (Baeyer, B. 19, 218°). H.F. 153,348 (Stohmann, J. pr. [2] 33, 471).

Formation.—1. By boiling phloretin with cone. KOHAq (Hlasiwetz, A. 96, 118).—2. By potash-fusion from quercetin, maclurin, catechin, scoparin, gamboge, dragon's blood, limetin, and bergaptene (Hlasiwetz, A. 112, 96; 119, 199; 127, 357; 134, 118, 283; 138, 190; Zwenger, A. 123, 154; Gautier, Bl. [2] 33, 583; Tilden a. Beck, C. J. 57, 323; Pomoranz, M. 12, 387).—3. By fusing resoroin with a large excess of NaOH, the yield being 65 p.6. (Barth a. Schreder, B. 12, 503).—4. By soda-fusion from phenol, benzene, trisulphonic acid, orein, and naringenin (Barth a. Schreder, B. 12, 422; M. 3, 649; Will, B. 20, 297).—5. By fusing its tricarboxylic ether with potash (Bacyer, B. 19, 3458).—6. By fusing z-di-bromo-phenol with potash (Blau, M. 7, 632).

Preparation.—By soda fusion from resorcin (Tiemann a. Will, B. 14, 954; 18, 1323).

Properties.—Trimetric crystals (containing 2aq); a:bic = *825:1:3*417. Melts at 200°. 200° when slowly heated. V. sol. water, alcohol, and ether; sl. sol. NaClAq. Tastes sweeter than sugar. May be sublimed. Its solution is ppd. by lead subacetate. FeCl., gives a bluish-violet colour. Reduces Felhing's solution and ammoniacal AgNO. Its alkalme solution absorbs oxygen and turns brown in air. Colours acidified pine-wood red. An alcoholic solution gives a red colour with HClAq and vanillin (Lindt, Fr. 26, 260), oil of cloves, or oil of pimento (Ihl, Chem. Zeit. 13, 264).

Reactions.—1. Browsine forms crystalline tribromo-phloroglucin and finally phlorobromin.

2. Chlorine passed into its aqueous solution forms tri-ohloro-phloroglucin C₀Cl₁(OH), 3aq [136°], which soon decomposes into tetra-chloro-acetone hydrate, and di-chloro-acetoacid (Webster, C. J. 47, 423; Zincke a. Kegel, B. 22, 1476). Chlorine passed into its solution in HOAc forms CHCl₂CO.CHCl, 4aq [49°]. Chlorine passed into a cooled solution of dry phloroglucin in chloroform forms CO CCl₂CO CCl₂ [48°], (269°), decomposed by water into CO, di-chloro-acetio acid, and CO (CHCl₂)₂—3. Dilute HNO, formanitro-phloroglucin.—4. Ammonia produces phloramine.—5. Nitrous acid in its ethereal solution forms phlorein. In acetic acid solution it gives tri-nitroso-phloroglucin (vol. iii. p. 619).—6. Aqueous HI at 140° forms nearly tasteless scales of phloroglucide C₂H₂O, 2aq, al. sol. warmwater. Phloroglucide is also got by heating phloroglucin alone or with POCl₂.—7. Heated with salicylic acid it forms two compounds of the form ChH₂CO C₂H(OH) CO C₄H₄, one of these (described by Kostanecki and Nessler) which vields an acetyl derivative C₂H₄O (OAc)

[318°]; the other isomeride [826°] crystallises from HOAe in green-yellow tables.—8. With or amido bendot aldehads and NaOHAq it forms red C₁,H₂NO₂, possibly di-oxy-acridine C₂H₄(OH), C₂H₄, which forms B'₁H₂PtCl₄ and C₁,H₁Bz₂NO₄ (Eliasberg a. Friedländer, B. 25, 1752).—9. Phenyl cyanats unites, forming C₂H₃(O.CO.NHPh), a yellowish powder [128°] (Goldschmidta Meissler, B. 23, 269).—10. Bensens sulphonic chloride added to the slightly alkaline solution forms C₂H₃(O.SO₄C₂H₃), [117°] (Georgesen, B. 24, 418).—11. Antiline at 210° forms triphenyl-tri-amido-benzene [193°] (Minunni, B. 21, 1984).—12. Phloretic acid at 170° forms C₃H₂O₁₄, or stallising from water in lamine (HJSiwetz, A. 119, 199).

Tri-oxim C_sH_a(NOH),. Formed from phloroglucin and aqueous hydroxylamine (Baeyer, B. 19, 159). Colourless crystals, v. sl. sol. water and alcohol, sol. alkalis and acids. Explodes at

155°.

Phenyl-hydrazine defivatives. The salt C_{*}H_{*}O3N,H_{*}Ph [76°-83°] is got from phloroglucin (1 mol.) and phenyl-hydrazine (3 mols.) in alcoholic solution (Baeyer a. Kochendörfer, B. 22, 2190). Nodules, sol. alcohol and ether. Cod MaOHAq sets free phenyl-hydrazine. In alcoholic solution it changes on keeping to C_{*}H_{*}(OH)(N,H,Ph)₂ [144°], which crystallises from toluene in needles, and yields a pentabonzoyl derivative [176°].

Tri-acetyl derivative C.H.(OAc).. [106°]. Got by heating phlorogluoin with AcCl.

Di-benzoyl derivatives C_sH₃(OH)(OBz), Two isomerides [165°] and [191°-195°] are got from phloroglucin with BzCl. The compound [165°] is more sol. benzene than the other (Skraup, M. 10, 391, 722).

Tri-benzoyl derivative C.H. (OBz). [174]. Formed, together with C.H. (OBz). [199], by warming phloroglucin with BzCl and NaOH (S.). Plates, sol. benzene.

Tri-methyl other C.H.(OMe). [52°]. (256°). Formed by passing HCl into a solution of phloroglucin in McOH, the resulting C.H.(OH)(OMe). being treated with MeI and KOH (Will, B. 21, 603). Crystals, in: A water and alkalis, v. sol. alcohol and ether. Conc. HNO, forms a blue solution. Bromine gives C.Br.(OMe). [145°]. When phloroglucin is treated with KOH and MeI the products are C.H.Me,O. [184°]. C.H.Me,O. [114°], and C.Me,O. [80°] (Margulies, M. 9, 1052; 10, 459). When tetra-methyl-phloroglucin is heated in sealed tubes with HClAq it yields isopropyl ketone, isobutyric acid, HOAc, and CO... Hence it would appear to be CMe. CO.CMe. CO.CH (Spitzer, M. 11, 104, 237). Hexamethyl-phloroglucin heated with InIAq at 200° produces isobutyric acid and C.H... and, on oxidation, yields di-isopropyl ketone. Hence it would appear to

be CMe₂CO.CMe₂CO.

Diethyl ether C₂H₁(OEt)₂(OH). [Wo].

Made by passing HCl into an alcoholic solution of phloroglucin or its carboxylic acid (Will a. Albrecht, B, 17, 2106). Long white needles.

May be distilled.

Tri-ethyl ether C.H.(OEt). [43°]. Got by heating the di-ethyl ether with Etl and alcoholic potash (W. a. A.).

Penta-ethyl derivative v. vol. ii. p. 505. Tri-phenyl ether CoH3(OPh),? [175°]. A product of the action of Na on phenyl acetate A product of the action of the (Hodgkinson, C. J. Proc. 2, 188). V. sl. sol. Aq. (Hodgkinson, C. J. Proc. 2, 188). BEOMO-DI-IODO-,

References.—Tri-Bromo-, Bromo-di-1000-,
Tri-Chloro-, Nitroso-, and Nitro- Phloroducin. PHLOROGLUCIN CARBOXYLIC ACID v.

TRI-OXY-BENZOIC ACID.

Phloroglucin tricarboxylic ether C13H18O. Phloroglucin tricarboxylio_ether *C_{1,3}H_{1,0}O₂, e. C₄(OH)₄(CO,Et)₄. [106°]. Formed from malonic ether and ZnEt, (Lang, B. 19, 2937). Prepared by dissolving Na (144 g.) in malonic ether (200 g.) at 100° and heating the product for six hours at 145° (Baeyer, B. 18, 33√7; Bally, B. 21, 1766). In this preparation an inhydride C_s(OH)_s(CO₂Et)_s<O [170°] is also formed. Needles (from dilute alcohol), insol. water. Does not react with nitrous acid gas.

Reactions .- 1: Potash-fusion yields phloroglucin.—2. Bromine in CS₂ ppts. bromo-phloro-glucin dicarboxylic ether [128°].—3. Chlorine gives tri-chloro-acetamide.—4. Phenyl syanate and C.H. at 200° form C.(O.CO.NHPh),(CO2Et), [195°] (Goldsohmidt a. Meissler, B. 23, 270). Eri-acetyl derivative C_s(OAc)₃(CO₂Et)₃.

[76°]. Needles (from alcohol or ether).

Oxim C₄H₄(NOH)₅(CO₂Et)₅. [171°].

PHLOROGLUCIN PHTHALEIN C,H,O, Formed by heating phloroglucin with phthalic anhydride at 170° (Link, B. 13, 1652). Minute orange needles, sl. sol. water. Its alkaline solutions are orange-red, without fluorescence. Zincdust and NaOHAq reduce it to phloroglucinphthalin C20H11O2, an amorphous reddish-yellow

PHLOROGLUCIN SULPHONIC ACID

C.H.SO. i.e. C.H.(OH). SO.H. Formed by mixing phloroglucin with H.S.O. (Schiff, B. 6, 26; A. 178, 191). Yields a crystalline K salt. POCl. converts it into the anhydrides C12II10S2O11, v. e. sol. water, and C12H2S2O10, Bl. sol. water, and C24H18S2O15.

PHLOROL v. o-ETHYL-PHENOL.

PULORONE v. XYLOQUINONE.

PHOBONE C₀H₁O i.e. CO(CH:CMe.)₂, Mol. w. 188. [28°]. (197°) at 743 mm. S.G. $\frac{32}{2}$ *885. $\mu_{\rm D}$ = 1·500 at 20° (Brühl, A. 235, 15). R_☉ 70·93 in a 14·5 p.c. benzene solution. Formed, the state of t together with mesityl oxide, by leaving acctone in contact with quicklime (Fittig, A. 110, 32). Formed also by the action of conc. HClAq on acetone (Baeyer, A. 140, 301), and by heating nitroso-triacetonamine with potash (Heintz, A. 187, 250). Yellowish prisms. Yields acetone, oxalic acid, and CO on oxidation with KMnO, (Pinner, B. 15, 591). Slowly combines with NaHSO, forming di-isobutyl ketone di-sulphonic acid. Yields \u03c4-cumene on heating with P2Os and mesitylene on heating with conc. H.SO. Yields mestlyl oxide on distilling with dilute H₂SO₄ (Claisen, A. 180, 18). Bromine in CS₂ torms C₂H_{1,2}Br₄O [88°]. Zinc and H₂SO₄ reduce it, in alcoholic solution, to decxyphorone C₁₈H₂₈O [108°]. HI forms C₀H₁₀I₂O [13°] (Kasaneff, B. 8, 485). Phorone does not react with benzoic aldehyde (Claisen, B. 14, 352).

Oxim C,H,;:NOH. [48°]. (218°). Tables. v. sol. alcohol (Nägeli, B. 16, 496).

Isophorone. The substance to which this name has been given is a mixture (Laycock, A. 258, 230).

CPr (Königs a. Eppens, B. 25,

Camphor-phorone C.H., O i.e. CH, CH,

co 260). (208°) (Kachler, A. 164, 79). Got by distilling calcium camphorate (Laurent, A. Ch. (2) 65, 329; Gerhardt 4. Liès-Bodart, A. 72, 293) and by heating camphor (1 pt.) with H₂SO₄ (4 pts.) at 100° (Schwanert, A. 123, 298). Colourless oil with aromatic odour. Inactive to light. PCl, yields C.II, Cl (205°). Yields amethyl-glutaric and acetic acids on oxidation.

Na followed by MeI yields C₃H₁₃MeO (225²-230°). Na followed by AcCl yields C₁₈H₂₇AcO₂ (230°-240°). Bromine in CS₂ forms C₂H₁₃Br₃O [52°1

PHORONIC ACID C, H, O, [184°]. Formed by saponification of its nitrile, which is got by boiling the product of the action of gaseous HCl on acetone with alcoholic potash (Pinner, B. 14, 1071; 15, 585). Large prisms (from dilute al-

cohol), sl. sol. water. - KHA" 1 aq: needles, v. sol.

condy, s. sol. water. — Riff 1, and 1 needes, v. water. — CaA" 3aq: prisms. — Âg, A" aq: pp. Ethyl ether Et, A". [125]. A mide. [above 300°]. Prisms. A hydride C₁H₁₀O₂. [138°]. Got heating the end at 100° Got by

heating the acid at 190° Imide C₁₁H₁₆O₃(NH). [205°]. Formed from

the anhydride and alcoholic NHa.

Nitrile C₁₁H₁₈N₂O₂. [above 320°]. **PHOSENE** v. SYNANTHRENE.

PHOSGENE GAS. Another name for COCl2;

v. Carbon Oxychloride, vol. i. p. 692. PHOSPHAM. (?)PN,II. When dry NH, is passed into well-cooled PCl,, a solid colourless mass is obtained, said by H. Rose to contain PCI, and NH, in the ratio PCI,:5NH, (P. 24, 308; 28, 529). This substance is probably a mixture of various compounds" other substances are formed if the PCl, is not cooled. If PCl, is treated with NH, at the ordinary temperature, 5NH, are absorbed by PCl, (H. Rose, l.c.); from this product ether dissolves out NaPaCle (v. NI-TROGEN PHOSPHECHLORIDE, vol. iii. p. 570); if the product is heated, HCl and NH Cl are evolved. and a white, loose powder remains, to which Gerhardt (A. Ch. [3] 18, 188; 20, 225) gave the composition PN₂H and the name phospham. Liebig a. Wöhler (A. 11, 139) obtained this compound by passing PCl, or PCl, over heated NH,Cl, and washing and heating the product; MI, (c), and washing and nearing the product, they supposed it to be PN₂. The same substance was obtained by Pauli (A. 101, 41) by heating an intimate mixture of P₂S₂ and NH₂Cl, also by heating red P with S and NH₂Cl, and by heating powdered Ca phosphide with S and NH,Cl, and washing the residue with an acid. Pauli's analyses showed less N than's required by the formula PN.H. By treating PCl, with NH, washing for a long time with water, digesting with HClAq, then with KOHAq, washing with water and then with ether, Salzmann (B.7, 494) obtained a substance resembling phospham and approximately agreeing with the composition P.N.H.; Salzmann regarded this substance as probably a mixture of several very similar compounds of P, N, and H. Besson (C. R. 114, 1264) says that PCl, absorbs 8HN,, and that on

heating PN₂H is formed.

Phospham is a white, loose powder; insoluble in ordinary solvents; melts and vaporises when heated in absence of air; oxidised by heating in air; yields HPO, and HN, when moistened with water and heated (Gerhardt, l.c.); fused with KOH or BaO,H, forms N.H, and orthophosphate, with incandescence.

Phospham may be regarded as one of the nitriles of H₂PO₄: thus PO₂OII.(ONH₂)₂-4H₂O = PN₂H; the other nitriles would be PON, which is known (v. Phosphorus oxyntradde, p. 144) [PO(OH)₂ONH₄-3H₂O = PON], and PN₃H₁, which has not been isolated [PO(ONH)₃-4H₂O = PN₃H₄]. Mendelejeff (B. 23, 3472 note) thinks it likely that phospham is a polymeride of PN₂H, inasmuch as it is analogous to N₁H (hydrazoic acid, vol. iii. p. 559) and both P and Compounds show a greater regaliness to polymerise than N and compounds of N. M. M. P. M.

PHOSPHAMIC ACIDS AND ALLIED COMPOUNDS. Two amic acids may be derived theoretically from PO(OII),, viz. PONH₂(OH), and
PO(NH₂)₂OH; both acids have been isolated.
The compound PO(NH), is described as
Phosphamide, and PO.NH.NH₂ as Phosphamide acids,
PS.NH₂(OII), and PS(NH₂)₂OH are probably
formed by the action of NH₄ on PSCl₃ (v. Threphosphamic acids,
PS.NH₂(OII), and PS(NH₂)₂OH are probably
formed by the action of NH₄ on PSCl₃ (v. Threthree amic acids (or salts of these) derivable from Il,PO, are known: P2O,NH₂(OH),
P2O₃(NH₂)₂(OH)₂, and P₂O₃(NH₂)₃OH. By heating P2O₄(OH)N is obtained. There are also several
acids (or their salts) known, which may be derived
from hypothetical P2O₄(OH)₃(2P2O₃(OH)₄ + H₂O
= P4O₅(OH)₃| by replacing OH by NH₂ or NH.
Imidophosphoric acid, PO.NH.OH, perhaps
exists.

Phosphamic asid PO.NH.(OH), (Amidophosphoric acid.) Obtained by Stokes (Am. 15, 198 [1893]) by suspending the lead salt in a little ice-water, decomposing by excess of H.S. and filtering into alcohol. White microscopic crystals; easily sol. water; does not give NH, with caustic alkalis; heated to 100° is slowly changed to an NH, salt, perhaps NH, PO,; aqueous solution soon changes to NH, H.PO,. Acid and mormal salts have been prepared. The lead salt is formed by adding lead acetate to a solution of PO.NH, OH.OK, which salt is produced by adding alcoholic NH, to an alcoholic solution of PO.Cl(OPh), and saponifying the PO.NH, (OPh), thus formed by KOHAq.

PHOSPHODIAMIC ACID PO.(NH₂)₂OH. (Diamidophosphoric acid.) Stokes (B. 27, 565 [1894]) prepared this acid by saponifying the product of the action of NH₂Aq on POCl₂(OPh). The acid gives salts PO(NH₂)₂OM, and also salts of an acid P(NH₂)₂(OH), (Abstract in C. J. 66 [11], 188 [1894]).

PYROPHOSPHAMIC ACID P₂O₃(NH₂)(OH)₃. This is said by Gladstone (C. J. 17, 229) to be the chief product of the action of NH₃ on P₂O₃; Schiff (A. 103, 168) formulated this product as PO.NH.OH, imido-phosphoric acid; Stokes (Lc.) says the product is a mixture. For details v.

G. (l.c.; also C. J. 3, 135; 21 64); also G. a. Helmes (C. J. 17, 225).

Pyrophosphonamic actd P₂O₃(NH₂)₂(OH)₃(G., C. J. 19, 290; G. a. H., Lc.). Formed by action of water or alkalis on N₃P₃Cl_s, by treating POCl₃ with conc. NH₃Aq, and in many other ways. A white amorphous solid, easily soluble in water and alcohol. The acid is dibasic. The salts are difficult to obtain pure, as they easily change into pyrophosphamates; salts of Ba, Ag, and Zn are described.

Pyrophosphatriamic acid P₂O₄(NH₂)OH (G., C. J. 19, 1; 21, 64). Dry NII, is passed into POCl, until saturated, the product is heated to 220° and boiled for a short time with water, the residue is washed with cold water, and then with a little dilute alcohol. A white, amorphous, tasteless powder, nearly insoluble in water; slowly acted on by cold water, more quickly by hot water, yielding P₂O₄(NH₂)₂(OH)₂Aq and NH₄Aq; boiled with HClAqqives H₂PO₄ and NH₄. Pyrophosphotriamates of NH₄ Ba, Cd, Co, Cu, Cr, Fe, Pb, Mg, Mn, Hg, Ni, Pt, K, Ag, Tl, and Zu are described; the acid is said to be tetrabasic.

Pyrophosphonytrallic acid P.O. (OH)N. The NH, salt of this acid is said to be formed by heating P.O. (NH.), OH, and the K salt by heating P.O. (NH.), OK (G., C. J. 22, 19).

TETTAPHOSPHAMIC ACIDS AND ALLIED COMPOUNDS. By the reaction of NII, with POCI, under different conditions, Gladstone (C. J. 21, 261; 22, 15), obtained various compounds which may be regarded as (1) tetrophosphodiamic acid P₁O, (NH₂)₁(OH)₄, (2) P₂O, (NH₂)₁(OH)₂ tetraphosphotetramic acid, (3) *tetraphospho-inidotetronide P₄O, (NII₂)₁NII (called by G. tetraphosphopentazotic acid), (4) *tetraphosphotimido-diamide P₄O, (NH₂)₂(NH)₂ (called by G. tetraphosphottrimic acid). Some of the above acids are regarded by Mente (A. 248, 232) as mildo-acids. M. M. P. M.

PHOSPHAMIDES. I. Phosphoric TRIAMIDE O.P(NH₂), (Phosphory) triamide) [derived from O.P(OH)₃ = H₃PO₄]. This compound is said by Schiff (4. 101, 300) to be obtained by passing NH₃ gas into POCl₃, and treating the product with water. It is described as a snow-white, amorphous solid; heated out of air gives NH₃ and PON dused with KOH gives NH₄ and K phosphate; scarcely acted on by boiling water, KOHAq, or dilute acids; soluble in hot cone. H₂SO₄; slowly attacked by boiling cone. HNO₃ or HClAq. Gladstone (C. J. 22, 18) could not obtain this compound.

Thiophosphamide is described under Thiophosphonyl chloride, Reactions, No. 7, p. 148.

M.M. P. M.

PHOSPHAMIDO-IMIDE PO.NH.NH. (Phosphoryl imido-amide. Formerly called Phosphodiamide) (Gerhardt, A. Ch. [3] 18, 188; Schiff, A. 101, 330). Obtained by saturating PCl, with NH., boiling the product with water as long as HCl pusses into solution, then boiling

with potash, then with HNO,Aq or H,SO,Aq, washing, and drying over H,SO, A white powder,insoluble in alcohol, water, or turpentine; heated out of air gives NH, and PON; heated in moist air gives NH, and HPO,; luced with KOH gives K phosphate and NH,; slowly exidised by fusion with KNO, but resists action M. M. P. M. of most oxidisers.

PHOSPHATES. Salts of the phosphoric acids. Besides the salts directly derived from the three phosphoric acids HPO, H,PO, and H.P.O. (v. Phospuorio Acids, p. 124), phosphates exist which are probably derived from hypothetical di-, tri-, or meta- phosphoric acid nHPO;; and a few salts have been isolated which are perhaps derived from the hypothetical acids P₄O₇(OH)₄ and P₁₀O₁₀(OH)₁₂.

Composition .- Orthophosphates are derived from H₃PO₄; they may be divided into classes according to the replacing powers of the metals: (1) monovalent metals form MH,PO, M,HPO, and M,PO,; (2) divalent metals form MH,PO, and M,PO,; (3) trivalent metals form MH,PO, and M,PO, and M,PO,; (4) tetravalent metals form MH,PO, and M,PO, and

Pyrophosphates are derived from H.P.O.; (1) salts of monovalent metals M₂H₂P₂O, and M₄P₂O₇; (2) salts of divalent metals MH₂P₂O, and M₂P₂O₇, &c.

Metaphosphates are derived from HPO.: (1) salts of monovalent metals MPO; (2) salts of divalent metals MP Os, &c. Various modifications of Na (and other) metaphosphates are known, all having the empirical formula MPO, but differing both in physical and chemical properties from one another; these salts were classified by Fleitmann a. Hanneberg (A. 65, 304; F., P. 78, 233, 338) as: (1) dimetaphosphates, salts of H₂P₂O_e; (2) trimetaphosphates, salts of H₂P₂O_e; (3) tetrametaphosphates, salts of H₂P₂O₁; and (4) hexametaphosphates, salts of H.P.O. Tammann (Z. P. C. 6, 122) has examined the electrical conductivities, and the depressions of freezing-points, of aqueous solutions of several di-, tri-, and hexa-metaphosphates; he comes to the conclusion that Fleitmann's dimetaphosphates should be represented in solution as $M_2(PO_3)$, (i.e. as trimetaphosphates), and the table is tri-salts when in solution are really M_s(PO_s)_s (i.e. dimetaphosphates). Tammann's results point to the existence in aqueous solution of 8 isomeric hexametaphosphates which nay be represented as (i.) M₂M₂(PO₃)_e e.g. Na₂.Na₄(PO₃)_e, K₂Na₄(PO₃)_e, K₂Na₄(PO₃)_e, K₃Na₄(PO₃)_e, K₄Na₄(PO₃)_e, K₄Na₄(PO₃)_e + Giii.) M₂M₄(PO₃)_e e.g. Na₄Na₄(PO₃)_e, Mil₃Na₄(PO₃)_e, There are also, according to Tammann, three different Na metaphosphates insoluble in water (v. also T., J. pr. [2] 45, 417).

Tetra- and deka-phosphates. Salts of the compositions $Na_*P_*O_{1}$ and $Na_{12}P_{10}O_{31}$ are obtained by fusing together Na_*P_*O , and $Na_{42}(PO_{3})_a$; these salts may be regarded as derived from the hypothetical condensed acids $H_1P_1O_{12}$ (= $(H_1P_2O_1 - H_2O)$), and $H_{12}P_1O_{13}$ (= $(H_1P_1O_1 - H_2O)$), respectively.

The composition of all the phosphates may be represented empirically with the expression.

be represented empirically by the expression nMO.mP,0,xH,0, where MO stands for a basic

Occurrence. -Phosphates of Al and Ca occur

in large quantitie. ______, vocae, purepurates of Fe, Pb, Mg, NH, &c. are also widely distributed minerals. Coprolites (the fossilised excrements of former land-animals), and guano (the excrement of certain birds) consist very largely of Ca phosphate. Phosphates occur in some kinds of coal, in the ashes of plants, and in the bones of animals.

Formation.—Some of the orthophosphates are obtained by reacting on HaPO Aq with metallic oxides or carbonates; others are formed by double decomposition from the alkali phosphates; when a metaphosphate is fused with a metallic oxide or hydroxide a normal orthophosphate is generally formed. Many pyrophosphates are obtained by double decomposition from Na,P₂O, which is formed by strongly heating Na,HPO₁; other pyrophosphates are found by neutralising H,P₂O,Aq by basic oxides or hydroxides. Metaphosphates are generally formed by strongly heating orthophosphates MH_PO, or MRHPO, when M or R is a metal whose oxide is volatile; many are produced by double decomposition from NaPO,; some are formed by heating Cu₂(PO₃), with a metallic sulphide and filtering from CuS.

The processes by which any one of the three classes of phosphates is formed from another is perhaps best understood by representing the phosphates thus:

meta pyro P₂O₃.2M₂O P,O,.M,O P2O3.3M2O Metaphosphate becomes pyro- by gaining M.O. and becomes ortho- by gaining 2M.O. and so on. Metaphosphate fuscil with metallic oxide, on. hetaphospiate used with metalic oxice, hydroxide, or carbonate yields pyrophosphate or orthophosphate, according to the quantities used; thus (1) 2NaPO₂+Na₂O₃=Na₁P_{.O}+CO₂; (2) 2NaPO₂+2Na₂CO₂=2Na₂PO₂+2CO₂. The metaphosphate of a heavy metal yields an orthophosphate of a heavy metal yields an orthophosphate of a heavy metal yields. thophosphate and H.PO, by boiling with water: thus 8AgPO, + 3II, O = Ag, PO, + 2H, PO, change from a pyro- to an ortho- phosphate is often effected by boiling with water, the product being an acid salt, thus Na, P,O, +H,O = 2Na₂HPO₄; or the pyrophosphate is fused with hydroxide or carbonate, thus

 $\operatorname{Ba}_{2}\operatorname{P}_{2}\operatorname{O}_{7} + \operatorname{Ba}\operatorname{O}_{2}\operatorname{H}_{4} = \operatorname{Ba}_{4}(\operatorname{PO}_{4})_{2} + \operatorname{H}_{2}\operatorname{O}_{4}$ Acid orthophosphates with one atom of H yield pywo-phosphates when strongly heated, e.g. 2Na₂HPO₁ - H₂O = Na₄P₂O₂; and those with two atoms of H yield metaphosphates, e.g. NaTl₁PO₄ - H₂O = NaPO₄.

Similarly a double orthophosphate of the form M₂Rl'O₄ yields a pyrophosphate on heating if R forms a volatile oxide, e.g. 2Na₂(NII₄)PO₄ = $Na_1P_2O_1 + H_2O + 2NH_3$. The removal of M₂O from a normal orthophosphate with formation of a metaphosphate is often effected by fusing with SiO₂ or B₂O₃ or other anhydride which forms a salt with M₂O₄, e.g. Na₂PO₄+SiO₂

forms a sait with m_AU, e.g. Ma_BEU₄TEIU₂ = NaPO₄+Na_SiO₄.

The metaphosphates formed by the processes sketched above belong to several series of saits all of which have the empirical formula saits all of Which have the Empirical formula saits all of Which have the Empirical formula saits and the SiO According to Electronia Hampherg nMPO. According to Fleitmann a. Henneberg (A. 65, 304; F., P. 78, 233, 338), these salts belong to five series.

Monometaphosphates MPO. Not many of these have been obtained with certainty; they are produced by heating alkaline oxider with

equivalent quantities of H.PO, to redness until the residue ceases to give an acid reaction (the temperature not being high enough to melt the mass), and washing the residue with cold water; some of the salts—e.g. NaPO, and KPO,—are formed by heating MH,PO, or M,H,P,O, to redness (c. 315°) till the residue is almost wholly insoluble in cold water (Maddrell, C. S. Mem. 3,

Dimetaphosphates M.P.O. The salts of Cu, Zn, and Mn are prepared by heating equivalent quantities of MO and H3PO, to redness. The

Na and NH, salts are obtained by decomposing the Cu salt by Na SAq or NH, sulphide solution, filtering, and ppg. by alcohol. These salts yield others of the series by double decomposition. The salts of this series are soluble in water and crystallisable. Tammunn (Z. P. C. 6, 122) thinks these salts are really trimetaphos-

phates (v. Properties and Reactions).

Trimetaphosphates M.B.O.. The salts of this series are crystalline. The Na salt is prepared by slowly heating NaNH, HPO, with frequent stirring, till the residue has a faintly acid reaction, treating with cold water, filtering, and allowing the filtrate to crystallise. The salt is also formed by heating NaNH, HPO, till a glassy mass remains, and cooling very slowly. other salts are obtained from the Na salt by double decomposition. Tammann (l.c.) regards these salts as dimetaphosphates (v. Properties and Reactions).

Tetrametaphosphates M,P,O12 beated with H.PO, to redness, as in making the Cu, Zu, and Mn dimetaphosphates (v. supra); the crystalline salt which is formed is insoluble in water, and much more easily decomposed by acids than the Pb salt got from Na,P,O. The Na salt is obtained by decomposing the Pb salt by Na SAq; and other salts are obtained from the Pb salt by double decomposition. Salts of Bi and Cd are obtained similarly to the Pb salt. These phosphates are uncrystallisable. Tammaun (J. pr. [2] 45, 417) says that CuNa₂P₄O₁₂ is the only salt which certainly belongs to this scries.

Hexametaphosphates M.P.O. NaNH, HPO. is heated till a glassy mass remains, which is cooled rapidly (Graham, T. 1838, 253). The Na salt yields others by double decomposition. These salts are non-crystallisable, and dry to resinous-like masses. Tammann's experiments (Lc.) seem to show that Na_sP_sO₁₈ is a mixture of several isomeric salts (v. p. 118).

Tammann (l.c.) describes salts belonging to the series of penta-, okto-, deka-, and tetrakai-

deka- metaphosphates.

Tetraphosphates M₂P₄O₁₃. A few of these sales have been prepared, e.g. Na₂P₄O₁₃ by fusing 2NaPO₂ + Na₄P₂O₃, and Ba₁P₄O₁₃ by fusing the Na salt with BaCl₂ (F. a. H., A. 65, 304; Uelsmann A. 118, 90)

mann, A. 118, 99).

Dekaphosphates M₁₂P₁₀O₃₁. The Na salt was obtained by fusing Na,P₂O, +8NaPO, (F. a. H., l.c.); some other salts were obtained from the

Properties and Reactions .- The orthophosphates MH.PO, dissolve in water, forming acid solutions; the dimetallic salts M. HPO, dissolve in water when M is an alkali metal, the solutions are feebly alkaline. Of the normal salts M.PO.

only those of the alkali metals are soluble in water; the solutions have an alkaline reaction. and are decomposed very easily, even by CO, forming M,HPO,Aq. Most of the heavy metals form only M,PO. Solutions of alkali orthophosphates give a yellow pp. (Ag,PO,) with AgNO, Aq, and a yellow pp. on warming with NH, molybdate solution. The orthophosphates M,PO, are not decomposed by heating strongly, unless they are salts of volatile bases; M,HPO, give M.P.O. and H.O. and MH.PO. give MPO. and H.O. when strongly heated. M.PO., M—alkali or alkaline earth metal, are not changed by heating with charcosi, but M.HPO, and MH.PO, give M.PO, and P. When M is a heavy metal, the salts M.PO, generally give metallic pl. sphides by heating with C. Orthophosphates heated with K or Na yield alkali phosphide. Many insoluble orthophosphates are decomposed by fusion with alkali carbonate, but those of the. alkaline earths are only partially decomposed. H.SO, decomposes all orthophosphates. When the salts M.PO, are heated with SO.Aq under pressure, M.HPO, or MH.PO, are formed (Pitter, Chem. Indust. 1878. 398; Gerland, J. pr. [2] 4,

Of the pyrophosphates, the normal alkali salts are soluble in water, with feebly alkaline reactions; the others are generally insoluble but dissolve in Na, P2O, Aq, forming double salts (H. Rose, P. 76; 13; Schwarzenberg, A. 65, 133; Persoz, A. 65, 163). Solution of pyrophosphates give orthophosphates when boiled with the stronger acids, or heated with water to 280° (Reynoso). M₄P₂O, are not changed by heat unless they are salts of bases decomposed by heat; M.H.P.O, give MPO, and H.O when strongly heated. All the pyrophosphates are changed to orthophosphates by heating strongly with sufficient alkali or alkali carbonate. Pyrophosphates of metals whose oxides are not reduced by H give orthophosphates and P2Os when heated in H; those which contain metals whose oxides are reduced by H, but not by heat alone, give metallic phosphide when heated in H; and those containing metals the oxides of which are reduced by heat alone, yield metal, H₁O, H₂PO, &c., when heated in H (Struve, J. pr. 79, 345). Pyrophosphates in solution average a white pp. with AgNO, Aq; they do not give an immediate pp. with warm NH, molybdate, and they do not coagulate albumen when acidified by acetic acid.

Some metaphosphates are soluble, others are insoluble, in water; some are crystalline, others are amorphous (v. supra: Formation of different classes of metaphosphates). Solutions of these salts in water are changed to orthophosphates on long-continued boiling; they give a white pp. with AgNO, Aq, no immediate pp. with NH, molybdate, and they coagulate albumen after

acidification by acetic acid.

Tammann (Z. P. C. 6, 123) has examined the electrical conductivities of solutions of Fleitmann's di- and tri- metaphosphates of Na; his results indicate that the ions of the salts in solution are Na_x and (PO_z)_x. He has also measured the depression produced in the freezingpoint of water by dissolving these salts therein; and, taking the results along with the electrical conductivities, he concludes that Fleitmann's di-

salts are tri-salts, and F.'s tri-salts are really | H,PO,Aq, or by ppg. BaCl,Aq by Na,HPO,Aq di-salts. By the reaction of AgNO,Aq on the soluble in 10,000 to 20,000 parts water, easily di salts. By the reaction of AgNo, Aq on the Ne, P, O₁, of Graham and Fleitmann, Tammann obtained a crystalline salt Ag, P, O₁, and two salts Ag, Na, P, O₁, and from these he formed three Na salts which he formulates as Na₅P₅O_{1n}, Na₁Na₂P₅O_{1n}, and Na₅Na₁P₅O₁, Measurements of the electrical conductivities of these salts confirm the above formulæ, and they tend to show that the ions of the salts in solution are Na, and Na, P,O,,, and Na, and NaP, O in respectively. A fuller examina-tion of Graham's salt led T. to conclude that it contains another isomeric hexametaphosphate

Na, Na, P,O10.

For detection and estimation of phosphates a manual of analysis must be consulted.

ORTHOPHOSPHATES. Salts derived from H,PO. (For thioxyorthophosphates v. Phos-

PHONIC SULPHIDE, p. 147.)
Aluminium orthophosphates. Many occur in minerals, e.g. angelite, fischerite, wavellite, tyrquois. The pps. obtained by adding Na,HPO,Aq to alum solutions vary in composition. They may be represented as $x\Lambda l_0 O_{31}$ yP_1O_{32} x being chiefly 1, 2, 3, and y being 1 and 2 (Munroe, A. 159, 638; Wittstein, J. B. 27, 167; Fuchs, S. 24, 121; Millot, C. R. 82, 89).

The normal salt, AIPO, xH, O, is obtained by gradually pouring neutral alum solution into excess of Na, HPO, Aq; a white loose powder; soluble mineral acids, soluble organic acids, soluble NH, citrate solution (Erlenmeyer, B. 14, 1869), soluble Al salt solution (Fleischer, Fr. 6, 28), soluble in potash; infusible at red heat, fused with Fe and SiO₂ gives Fe phosphide (Schlösing, C. R. 67, 1247); partially decomposed by fusing with K₂CO₃ (Rammelsberg, P. 64, 405; cf. Vauquelin, A. Ch. [2] 21, 138). When air-dried x = 4 to 5; dried over H₂SO₄, x = 8 (Rammelsberg, Millot, Wittstein). For other phosphates of Al v. Rammelsberg (l.c.), Schweitzer (B. 3, 310; 6, 28), Ludwig (Ar. 1th. [2] 59, 19), Hautefeuille a. Margottet (C. R. 106, 135), Erlenmeyer (Z. 3, 572).

Double salts with phosphates of Ca, Li, and Mg have been described (v. Gm. K., i. 2. 670).

American orthophosphates. The normal salt, Am, PO, 3H,O, crystallises in short pyramids, obtained by treating Am2HPO, with conc. NH, Aq (Berzelius, Gm.-K. i. 2, 527). Loses twothirds NH, by boiling water (Kraut, C. C. 1855. 894). Sestini (B. 11, 1927) obtained a salt with The di-ammonium salt, Am, HPO, is formed in monoclinic prisms by allowing NH, or (NH₄)₂CO₃ in H₃PO₄Aq to evaporate; soluble four parts cold water, solution is alkaline; on boiling NH, is evolved; S.G. 1.62-1.67 (Rammelsberg, B. 3, 278; Schiff, A. 112, 88; Buignot, J. 1861. 15; Proust a. Brooke, Gm. K. i. 2, 528). The mon-ammonium salt, AmII, PO,, crystallises in quadratic forms, isomorphous with KH,PO,, by adding NH,Aq to H,PO,Aq till BaCl,Aq ceases to give a pp. S.G. 1758 (Schiff, Lc.; ceases to give a pp. S Mitscherlich, P. 19, 385).

Barium orthophosphates. The normal salt, Ba, P₄O₈, is a heavy white solid, obtained by ppg. BaCl.Aq by Na, PO, Aq (Graham; Rotondi, B. 15, 1441). Two acid salts have been obtained: -(1) Baliro, by boiling the normal salt with

soluble if NH, salts, BaCl, or NaCl is present soluble in H,PO,Aq or dilute HNO,Aq (Berzelius Ludwig, Rose, Brett, Wittstein, Bischoff, Malaguti, Gm.-K. i. 2, 272; Skey, C. N. 22, 61; Erlenmeyer, J.1857. 145; Sotschenoff, C. C. 1875. 97; Gerland, J. pr. [2] 4, 125); (2) BaH, P.O., from a solution of BaHPO, in H, PO,; white triclinic crystals; decomposed by much water to H.PO.Aq and BaHPO. (Berzelius).

Double salts.—(1) BBa,P.O.,BaCl. (Rose, P. 8, 211; Ludwig, Ar. Ph. [2] 56, 265; Deville

a. Caron, A. Ch. [3] 67, 451); (2) 4BaHPO, BaCl₂ (Erlenmeyer, J. 1857, 145); (3) BaNaPO, 10H₂O (Rose, Guyton, Berzelius, Gm.-K. i. 2, 313; de Schulten, Bl. [2] 39, 500; Joly, C. R. 104, 1702); (4) BaKPO, 10H₂O (de S., L.c.).

Beryllium orthophosphates. The normal salt, Be, P,O,, is a white pp., obtained by adding Na.HPO.Aq to solution of a salt of Be. An acid salt is obtained by dissolving the normal

salt in H₃PO₃Aq (Vauquelin, Gm.-K. i. 2, 269).

Double salts. Be.NH, and Be.K phosphates are known (Rössler, Fr. 1878, 148;

Ouvrard, C. R. 110, 1333).

Bismuth orthophosphate BiPO,. powder, obtained by adding Bi,O,xH,O to H.PO Aq; little known (Wenzel, Gm. K. i. 2, 832; Chancel, C. R. 50, 416).

Cadmium orthophosphates. salt, Cd, P,O,, is obtained as an amorphous pp. by adding Na, PO, Aq to a Cd salt solution (de Schulten, Bl. [3] 1, 473).

Acid salts (de S., l.c.): (1) Cd, H₂P₄O₁₆.4H₂O₄ by ppg. hot CdCl₂Aq by Na₂HPO₄Aq. (2) CdH, P.O. 2H.O. by dissolving the foregoing

salt in cold dilute H,PO,Aq and allowing to evaporate at ordinary temperature.

Double salt 3Cd₃P₂O₃, CdCl₂ (de S., l.c.). Calcium orthophosphates. Ca phosphates are widely distributed minerals.

Normal salf Ca, P,O,. Obtained, as a white amorphous powder, by adding NH,Aq to solution of bone-ash in HClAq or HNO₃Aq; by adding Na₃PO₄Aq, or a mixture of Na₂HPO₄Aq and NH3Aq, to CaCl Aq. For details of preparation from phosphorite, or bone-ash, &c. v. DICTIONARY of Applied Chemistry. The pp. from CaCl₂Aq in presence of NII₄ contains 5H₂O according to Wittstein (J. 1866, 168; v. also Ludwig, Ar. Ph. [2] 69, 286). Slightly soluble in water; one litre cold water dissolved 79 mgm. freshly ppd., and 31 mgm, strongly heated, Ca₃P₂O₈ (Völcker, J. 1862. 131). Decomposed slowly by boiling water into CaH₄P₂O₈ and 2Ca₃P₂O₈CaO₂H₂ (Warington, C. J. [2] 11, 983). Solubility in water is increased by small quantities of alkali salts (v. Wöhler, P. 4, 166; Liebig, A. 61, 128; Lassaigne, J. 1847. 341; Thomson, Ann. Philos. 17, 12; Völcker, J. 1862. 131; Fresenius, Fr. 10, 133; Hüncfeld, Delkeskampt, Morveau, Gm. K. i. 2, 367; Terreil, Bl. [2] 35, 548; Erlenmeyer, B. 14, 1253). Presence of starch and various organic substances increases solubility in water (v. Wöhler, A. 98, 143; Hayes, N. Ed. P. J. 5, 378). Soluble in CO_Aq; CaCO₂ and CaHPO₃ separate on standing (Liebig, A. 106, 196; Warington, C. J. [2] 4, 296; Dusart a. Pelouze, C. R. 66, 1327; von Georgievics, M. 12, 566).

Partially decomposed by boiling with NaOHAq, or by fusing with Na₂CO₂ (Wöhler, A. NaOHAQ, or by fusing with Na_cCO_c (Wöhler, A. 51, 437; Rose, P. 95, 437; Fresenius, Fr. 10, 133). Easily changed to CaC_cO_c by boiling with (NH_c)_cC_cO_cAq (Fresenius, Lc.).

Strongly heated with C and SiO_c gives Ca silicate, P, and CO; heated in CO, all P is set free (Schlösing, C. R. 59, 384; Anderson, B. 5, 1065).

1065). Heated with Na, K, or Mg, metallic phosphide is formed (v. Gm.-K. i. 2, 366).

Dissolved by SO₂Ag; on standing, CaHPO₄ and CaSO₂ separate (c. Gerland, C. N. 20, 20s; Aldred, C. N. 42, 177; Rotordi, B. 15, 1441). Dilute H,SO,Aq forms CaHPO, or CaH,P,O, or CaSO, and H,PO, according to the quantities of H2SO, and Ca2P2O, the temperature, and the time of action (v. Gm.-K. i. 2, 369; Kolb, C. R. 78, 825; Joulie, C. R. 76, 1288; Crum, A. 63, 394). For the (similar) reactions with HClAq and HNO, Aq v. Crum, l.c.; Piccard (J. 1886, 168); Bischof (S. 67, 39); Birnbaum, a. Packard (Z. [2] •7, 137); Tissier (C. R. 38, 192); Warington (C. J.

[2] 4, 302).

Double salts. (1) Ca,P,O,Ca,SiO, (Carnot a. Richard, C. R. 97, 316). (2) 3Ca₃P₂O₈.CaCl₂by fusing Ca₃P₂O₈ with NaCl, or heating to 250° with CaCl Aq, or passing PCl, vapour over glowing lime (Forehhammer, P. 91, 568; Debray, A. Ch. [3] 61, 424; Daubrée, Ann. M. (4) 19, 684; Deville a. Caron, A. Ch. [3] 67, 451). 584; Deville a. Caron, A. Ch. [3] 67, 451].
(3) 3Ca,P₂O, CaP₂; occurs native as apatite (with varying quantities of CaCl.); obtained by fusing Na,HPO, CaF₂, and CaCl. (D. a. C., l.c.; Briegler, A. 97, 95). (4) Ca(NH,)PO, xH, Cherical a. Fenerlein, Fr. 1881. 191).
(5) CaKPO, (Rose, P. 77, 291). (6) CaLiPO, (Rose, P. 77, 291. Rome, A. 172, 18).

291; Bungo, A. 172, 18).

Acid salts. I. Dicalcium phosphate
Ca.H.P.Q.. Obtained by adding Na HPO,Aq, or
NaNH,HPO,Aq, to excess of CaCl,Aq; pp. contains a little Ca,P,O_a; also by the action of CO,Aq on CaCO, and (MI), HPO, Aq (Becquerel, C. It. 34, 573); and by acting on powdered CaCO, with H, PO, Aq (Debray, A. Ch. [3] 61, 424); by passing CO₂ into H₂O, holding freshly ppd. Ca.P₂O₃ in suspension (Percy, P. M. [3] 26, 194; Reichardt, Ar. Ih. [3] 2, 236). Obtained in crystals by allowing solutions of (NH4),HPO, and CaCl, to mix slowly through a porous cell (Vohl, A. 88, 114), or through a layer of water (Drevermann, A. 87, 120); also by allowing a solution of amorphous CaHPO, in a weak acid to evaporate (Bödeker, A. 69, 206; Baer, P. 75, 152; Vorbringer, Fr. 9, 457; v. also Causse, J. I'h. [5] 21, 544). CaHPO, ppd. at low temperatures and dried quickly at 100° contains 2H₂O, which is lost by long drying at 100° in a stream of dry air. Forms Ca.P.O, when strongly heated; decomposed to Ca₂P₂O₃ and CaH₄P₂O₅ by long boiling with water. For description of various hydrates xCaHPQ.yH.O v. Vorbringer (Fr. 9, A57), Gerland (J. pr. [2] 4, 104), Millot (Bl. [2] 33, 194), Skey (C. N. 22, 61), Dusart a. Pelouze (C. R. 66, 1827), Davies (C. N. 64, 287). Soluble in boiling NH,ClAq (Kraut, Ar. Ph. [2] 111, 102); soluble SO₂Aq (Gerland, J. pr. [2] 4, 123), in HClAq and HNO₂Aq (Berzelius, Baer, Gm. K. 1.2, 372). Decomposed by boiling alkali carbonate solutions (Malaguti (Fm. K. i 2, 373)) solutions (Malaguti, Gm.-K. i. 2, 373)

II. Monocalcium phosphate CaH, P,O, H,O.

This salt is the chief constituent of artificial superphosphate of lime prepared by treating crushed bones, phosphorite, &c., with H₂SO₄ (r. Dictionary of Applied Chemistry). Prepared by dissolving Ca₂H₂P₂O₃ in 31 p.o. H₃PO₄Aq, crystallising, washing with absolute alcohol, then with ether, and drying (Stoklasa, Listy Chem., 13, 203, 240, 273; abstract in C. J. 58, 695). 13, 203, 240, 273; austract in C. J. ec, out, This salt is also formed by evaporating Ca,H,P,O, with HNO,Aq+H,SO,Aq. Also by leaving a solution of the commercial honey-like monocalcium phosphate in contact with Ca,P,O. for some time, and evaporating the solution formed at a gentle heat; the salt is thus obtained in crustals (Pointet, Bl. [3] 5, 254). Not hyg oscopic; the hygroscopic nature of the prepication made by Birnbaum and others is said by Stoklasa (l.c.) to be due to traces of H.PO. Thin rhombic plates (v. Haushofer, Z. K. 7, 263); S.G. 2-02 (Schröder, B. 11, 126). Loses H.O at 100°, decomposes at 200° to mixture of CaP,O. and Ca,P,O, (Birnbaum, B. 6, 898). Decomposed by H,O. Stoklasa (l.c.) represents the decomposing action of water as

 $xCaH_{\bullet}P_{\bullet}O_{\bullet}.H_{\bullet}O + H_{\bullet}O$ =(x-1)CaH $_{\bullet}P_{\bullet}O_{\bullet}.H_{\bullet}O + CaH_{\bullet}O_{\bullet} + 2H_{\bullet}O + H_{\bullet}PO_{\bullet}$; the greater the quantity of water the more salt is dissolved without decomposition; with 200 parts H₂O to 1 part salt a clear solution is formed without any free H,PO4; above this limit Call, P2O, is re-formed from the products of its decomposition (for older observations v. Birnbaum, Lc.; Erlenneyer, N. J. P. 7, 225; Warington, Pr. 1880, 243). According to Reynoso (C. R. 34, 795), water at 280° decomposes the salt, forming HaPO, and crystalline CasP.O.

salt, forming H₁PO₄ and crystalline Ca₂P₄O₄. Various salts produce Ca₂H₂P₂O₄ from solutions of Call₄P₂O₆ (v. Debray, A. Ch. [3] 61, 421; Dusart a. Pelouze, C. R. 66, 1327; Vorbringer, Fr_{e0}, 457; Erlenmeyer, L.:; Birnbaum, L.c.). Cerium orthophosphate CePO₄. By fusing Cc₂O₃ with KPO₃; also by digesting Cc₂K₄(PO₁)₂ with KClAq. Monoclinic prisms; S.G. 3.8 (Ouvrard, C. R. 107, 37). The double salt Ce_K₃(PO₄), is formed by fusing K₂PO₄ or K₄P₂O₇

Chromium orthophosphates. The normal chromic salt, Cr₂P₂O₈, is known in two forms, green and violet. Violet form, Cr.P. 72H.O. a violet crystalline pp. by adding Na, HPO, Aq to excess of Cr alum solution; loses 7H, O at 100°, becoming green; changed to green by conc. HNO, Aq. H. SO., or PCl. (Rammelsberg, P. 68, 383; Etard, C. R. 84, 1091). Green form, CraP2O.6H2O, by adding excess of Na.HPO.Aq to Cr alum; also by ppg. a slightly acid solution of a Cr salt by Na, IIPO, and Na acctate (llose, P. 77, 291, 298; Carnot, Bl. [2] 37, 482; Vauquelin, Cm.-K. i. 2, 304). Soluble mineral acids, also KOHAq (v. Dowling a. Plunkett, Chem. Gazette, 1858, 220; Känimerer, Fr. 12, 375). Gives alkali chromates by fusion with alkali sulphates (G. andeau, C. R. 95, 921). Forms a double salt with Ca (Dingler, D. P. J. 212, 532; Plessy, Rép. Chim. app. 1862. 453; Köthe, D. P. J. 214, 59). The acid salt CrH, P.O., 8H, O is probably formed by dissolving Cr.O., xH, O in H, PO, Aq (Vauquelin, Gm.-K. i. 2, 304; Haushofer, Z. K. 7, 263).

Chromous orthophosphate Cr.P.O. H.O. a blue pp. by adding Na,HPO,Aq to CrCl,Aq; quickly becomes green in air (Moissan, A. Ch.

[5] 25, 401). Cobalt orthophosphates. The normal salt Co.P.O..xH.O is formed by heating CoHPO..3H.O with water, or with Co(NO.).Aq, to 250° in a sealed tube (Debray, A. Ch. [3] 61, 438); also by treating Co(NH.)PO.6H.O with boiling water (Chancel, Precis d'analyse [Paris, 1862] 1, 263). In this salt x=2. A salt with x=8 is said to be formed by ppg. CoH₁P₂O₂Aq by alcohol (Reynoso, C. R. 34, 795; Reitler, Vierteigahr. Pharm. 7, 246). Two acid salts are known: (1) CdHPO₂, 3H₂O, by boiling CoCO₃ with H₃PO₂Aq, or boiling solution of a Co sait with Call, P.O., (Debray, J. Ph. [3] 40, 121); a salt with 5H,O was obtained by Bödeker (A. 94, 557). (2) CoH,P.O., by helying Co pyrophosphate with water to 280° (Reyndso, C. II. 34, 795). Double salts: NH, salts v. Dirvell, C. R. 89, 903; Popp, Z. [2] 6, 305. For luteo- and roseo- cobaltamine phosphates v. Gibbs a. Genth, Am. S. [2] 21,86; 23, 234, 319; Braun, Gm.-K. i. 8, 463; Porumbaru, C. R. 93, 463; Porumbar 842. For K and Na double salts v. Ouvrard, C. R. 106, 1729.

Copper orthophosphates. Normal salt Cu,P,O, 3H,O, obtained by adding a little Na,HPO,Aq to excess of a Cu salt solution (Mitscherlich, Gm.-K. i. 8, 614); also by heating CuCO, with H,PO,Aq to 70° (Debray, A. Ch. [3] 61, 437). A blue-green powder; decomposed by hot water under pressure (Debray; v. also Reynoso, C. R. 31, 1795; Jörgensen, Gm.: K. i. 3, 615). Basic salts and acid salts are known; composition doubtful (v. Rammelsberg, P. 68, 383; Metzner, A. 149, 67). For double salts with NH, v. Metzner, l.c., and Schiff, A. 123, 41; with Na, v. Weineck, A. 156, 57; with K, also with Na. v. Ouvrard, C. R. 111, 177. For an account of the salts produced by the reaction of Na,HPO,Aq with CuSO,Aq and Cu(NO₃),Aq v. Steinschneider, C. C. 1891, ii. 51 (abstract in C. J. 60, 1423).

Didymium orthophosphate DiPO,: also double salts with alkali metals (Ouvrard, C. R.

Iron orthophosphates. Ferrous salts. The normal salt Fo.P.O., SII, O occurs native as accounte; it is obtained by ppg. FeSO, Aq with oxcess of Na.HPO, Aq, and digesting at 60°-80° for eight days. Small monoclinic crystals (Ranmelsberg, P. 64, 251, 405), nearly colourless but becoming blue in air (Debray, C. R. 59, 40). A salt with one H.O is obtained by heating Fe₂H₂P₂O₈.4H₂O with water at 250° (Debray, A. Ch. [3] 61, 437). Various acid salts are obtained by dissolving Fe in H₂PO₄Aq; if the materials are air-free, and evaporation is effected in CO2, the salt Fe2H2P2O2.4H2O is formed (Erlenmeyer, Debray, Rammelsberg, l.c.). For double salts with NH, v. Otto, J. pr. 2, 409; and Debray, C. R. 59, 40. Ferric salts. The normal salt FePO, is

obtained by ppg. FeCl₃Aq by Na₂HPO₄Aq; dried at 50° contains 8H₂O, at 100° contains 4H₂O, dehydrated by heating strongly; also formed by oxidation in air of Fe₃P₂O₈ (Debray, Rammelsberg, Wittstein, *l.c.*). Whether the salt ppd. from FeCl, Aq in presence of acetic acid is the normal or a basic salt is undecided (v. Winkler, J.

Wackenroder a. Ludwig, Ar. Ph. [2] 53, 1; Mohr Fr. 2, 520). FePO, xH₂O is sol. c. 1500 parts boiling water; but is decomposed (Lachowicz, M 13, 357). Acid salts are obtained by dissolving 13, 357). Acid salts are obtained by dissolving Fe,O₄xH₂O in H₂PO₄Aq: Erlenmeyer got FeH₂P₂O₁ by evaporating quickly (v. also Waine, C. N. 36, 132; Wagner, Chem. Zeitung, 1881. 247). Hautefeuille a. Margottet (C. R. 106, 1357). obtained various ferric phosphates by dissolving Fe₂O₂xH₂O in glacial phosphoric acid.

Lanthanum orthoph sphate LaPO : tiouble salts with K and Na (v. Ouvrard, C. R.

107, 37).

Lead orthophosphates. The normal salt, Pb,P₂O₃o is ppd. as a white powder by adding Na,HPO₄O₄o to Pb acetate solution (Berzelius; Mitscherlich, Gm. 3; v. also Heintz, P. 73, 119; Gerhardt, A. Ch. [3] 22, 505; Haushofer, Z. K. 7, 264). A double salt with PtCl, is obtained 7, 204]. A abuste satt with Prof.; is obtained by action of Na,HPO, Aq on PbCl. (Debray, A.Ch. [3] 61, 419; Manröss, A. 82, 348; Deville a. Caron, A. Ch. [3] 67, 451). By ppg. boiling Pb2NO,Aq by H,PO,Aq, Heintz (P. 73, 119)

POZNOJAQ by H.PO.AQ, Heintz (P. 73, 119) obtained the acid sadt Pb.H.P.O.

Lithium orthophosphates. The normal salt, Li,PO.H.Q(?Li,PO.H.Q). By heating Na₂HPO.Aq with solution of a salt of Li (Mayer, A. 98, 183; v. also Berzelius, P. 4, 245; Rammelsberg, C. N. 38, 240, also B. 15, 283; Fresenius, Fr. 1, 42; Kraut, A. 182, 165). Loses H.O at 100°. Obtained in rhomboidal tables, S.G. 241 at 15°, by dissolving in fused LiCl (de Schulten, Bl. [3] 1, 479). Soluble in c. 2,540 parts water. Acid salts: LiH₂PO, and LiH₃P₂O₈.H₂O, by dissolving normal salt in

H.PO.Aq (Rammelsberg, l.c.).

Magnesium orthophosphates. The normal salt, Mg,P,O,xH,O, is obtained with 4H,O by ppg. Mg salts by alkali phosphate and drying at 100° (Graham; Rose, P. 76, f4; Gregory, A. 54, 98; Stein a. Tollens, A. 187, 79; gory, A. 54, 98; Stein a. Tollens, A. 187, 79; Fresenius). Forms monoclinic crystals (lifuushofor, Z. K. 6, 187). Very slightly soluble water (Völker, J. 1862. 131). For solubility in salt solutions v. Liebig (A. 106, 185), and in citric acid v. Erlenmeyer (B. 14, 1253). Soluble SO₂Aq (Gerland, J. pr. [2] 4, 126; Rotondi, B. 15, 141). Crystals with 6H₂O separate from MgSO₃Aq + Na₄HPO₄Aq at 36° and upwards; delta to the constant of t and at lower temperatures a salt with.14H,O is natural forms to the temperature a sair with 1411,0 is obtained (v. Percy, P. M. [3] 26, 194; Reischauer, N. R. P. 12, 43; 14, 57).

Acid salts. 1. MgHPO, xH, O (x = 6,7,8,9);

by dissolving magnesia alba in H₂PO₂Aq (Bergmann, Fourcroy, Gm.-K. i. 2, 446; Debray, J. pr. 97, 116; Haushofes, Z. K. 7, 257).

2. MgH₂P₂O₈; by boiling the foregoing acid salt with water (Schaffner; Rotondi, B. 15, 141).

Double salts. Magnesium-ammonium orthophosphate MgNH, PO, 6H,O. By adding Na, HPO, Aq to a Mg salt to which NH, ClAq and excess of NH, Aq have been added; or by adding a mixture of H.PO.Aq and excess of NH.Aq to a a mixture or H₁PO₁Aq and excess or NH₂Aq to a Mg salt. For experiments on different conditions of formation v. Graham (A. 27, 25); Riffault (At Ch. [2] 19, 90); Mohr (Fr. 12, 36); Gibbs (C. N. 28, 51); Lesieur (C. R. 59, 191); Steina. Tollens (Gm.-K. 1, 2, 476); Kubel (Fr. 8, 125); Kissel (Fr. 8, 164); Brunner (Fr. 11, 80); Berzelius (P. 4, 275); Heintz (Fr. 9, 16). Obtainer in large grystals by separating the reacting prokt. Pharm. 5, 837; Heydenrich, C. N. 4, zelius (P. 4, 275); Heintz (Fr. 9,16). Obtained 158; Struve, N. Peters. Acad. Bull. 1, 465; in large crystals by separating the reacting

liquids by a membrane (Vohl, A. 88, 114; Nonier, C. R. 78, 800; Millot, Bl. [3] 18, 20; Millot a. Maquenne, Bl. [2] 23, 238). Loses NH, in air; strongly heated gives Mg.P.Q., For in air; strongly heated gives Mg.P.O., For solubility in various solutions v. Fresenius (A. 55, 109); Ebermayer (Jopr. 60, 41); Liebig (A. 106, 196); Völcker (J. 1862, 131); Kissel (Fr. 8, 173); Gerland (J. pr. [2] 4, 127); Millot (Bl. [2] 18, 20); Ville (C. R. 75, 344). Another Mg.NH, phosphate is described by Gawalovski (G. C. 185, 791). (C. C. 1885. 721). For other double salts : with MgCl₂, v. Deville a. Okron (A. Ch. [3] 67, 456); with MgCl₂ and MgF₂, v. Bischof (D. P. J. 237, 51, 136); with MgCl₂ and CaF₂, v. D. a. C. (l.c.); with K, v. Haushofer (Z. K. 7, 257), Ouvrard (C. R. 106, 1729); with Na, v. Rose, Berzelius, &c. (Gm.-K. i. 2, 476), Ouvrard (l.c.).

Manganese orthophosphates. Normal manganic orthophosphate, MnPO, H,O, a greenish grey pp. by adding conc. Mn(NO3), Aq to H3PO, and a little boiling water (Christensen, J. pr. [2] 28, 1). For properties of products of reaction of 25, 1. For properties of produces treatment of the Pool of the Poo

Mn,P,O, wH,O. Obtained with 14H,O by ppg. MnSO,Aq by Na,HPO,Aq; loses 7H,O over H,SO, and one more H,O at 100° (Erlenmeyer, A. 190, 208). Salts with 9 to 11 H.O. 7H.O. and 3H2O are obtained by decomposing MnHPO ... xH2O by water, and drying under different conditions (E., l.c.). The salt without H₂O is formed by strongly heating the hydrates, also by heating Mn,P,O, in H (Struve, J. 1860. 73). A white amorphous pp., soluble mineral acids and acetic acid, and various salt solutions (v. Berzelius, Gm. K. i. 2, 472; Heintz, P. 74, 449; Joulin, A. Ch. [4] 30, 272; Gerland, J. pr. [2] 4, 97; Wittstein, Gm. K. 2, 472; Braun, 14. 7, 340; Erlenmeyer, B. 14, 1253).

Various acid salts have been described:— 1. MnHPO, 3H₂O (Bödeker, A. 69, 206; Heintz, P. 74, 449; Erlenngeyer, A. 190, 208].—2. MnH₁P₂O_{**}2H₂O (Heintz, Erlenneyer, l.c.).—3. Mn₁P₂O_{**}MnHl²O_{*}XH₂O (Erlenmeyer, l.c.; Haushofer, Z. K. 7, 257). Double salts: with MnCl. (Deville a. Caron, A. Che [3] 67, 459); with Fe.P.O. and MnCl. and with Fe.P.O. and MnF. (D. a. C., l.c.); with NH. (Otto, S. 66, 288; Heintz, l.c.); with K and with Na (Ouvrard,

C. R. 106, 1729).

Mercury orthophosphates. Normal mercurous orthophosphate, Hg,PO, by ppg. excess of Na₂HPO, Aq by HgNO, Aq (Gerhardt, J. 1819. 283). Brooks (P. 66, 63) describes a basic sait. A double salt with HgNO, is described by Gerhardt (l.c.; v. also Gm.-K. 3, 918). Normal mercuric orthophosphate, Hg.P.O., is obtained by heating Hg,PO, to low redness, also by adding strongly acidified Hg(NO₃),Aq to Na₂HPO,Aq (v. Gm. K. 3, 754, \$18; also Hanck, C. C. 1890. [2] 736). For a double salt Hg.NH,Hg,O.PO. v. Hirzel (Gm.-K. 3, 820).

Nickel orthophosphates. The normal salt Ni₂P₂O₂.7H₂O is obtained as a green floculent pp. by adding Na, HPO, Aq to a Ni salt; heated strongly loses 7H₀ (Rammelsberg, P. 68, 383; Struve, Gm.-K. 3, 543). Double salts: with NH₄ (Debray, C. R. 59, 40); with Mg (Rose,

Gm.-K. 8, 508); with Na and with K (Debray. Lc.; Ouvrard, C. R. 106, 1729).

Potassium orthophosphates. K.PO. A white solid, obtained by adding excess of K.CO, to H.PO.Aq, and evaporating; slightly soluble cold water, more soluble hot water. Acid salts: 1. K.HPO, [Graham, Funke, Gm.-K. 2, 30). 2. KH,PO,; by dissolving K,CO, in somuch H,PO,Aq that blue litmus paper is turned red but goes blue again on drying. Colourless tetragonal crystals; very soluble water; at red heat gives KPO,; S.G. 2.29 to 2.4 (v. Gm.-K. 2, 30; also Senarmont, A. Ch. [3] 33, 391; Schiff, A. 112, 88; Buignet, J. 1861. 15).

Silver orthophosphates. Normal salt Ag. O., a yellow solid, obtained by adding an al Mi phosphate to AgNO,Aq (Wetzlar, Gm. K. 3, 918; Skey, C. N. 22, 61; Lassaigne, ₱ Ph. [3] 16, 289; Joly, C. R. 103, 1071). The acid salt Ag, HPO, forms, in white hexagonal crystals, from a solution of the normal salt in H,PO,Aq (Berzelius, P. 2, 163; Hurtzig a. Geuther, A.111, 160; Schwarzenberg, A. 65, 162; Joly, C. R. 103, 1071).

Sodium orthophosphates. The normal salt, Na₃PO₆12H₂O, is obtained by adding excess of NaOHAq to Na₃HPO₆Aq and evaporating. Sixsided pyramids; melt at 77°; S.G. 1.618 (Schiff, A. 112, 18); soluble in 2 pts. water at 15°; solution absorbs CO₂ from air, giving Na,HPO,Åq. The anhydrous salt, Na,PO, is obtained by heating the salt with 12H,O, or by heating Na₂HPO₄.12H₂O with NaOH in equal molecular proportions (Graham, Mitscherlich, Gm.-K. 2, 163). S.G. 2.511 at 12°, 2.536 at 17.5° (Clarke's Table of Specific Gravities). For experiments on diffusion of the different Na orthophosphates v. an Bemmelen, B. 11, 1675; Hinteregger, B. 11, 1619; Tobias, B. 15, 2452. Disodium hydrogen orthophosphate

Na, HPO, .12H, O. (Ordinary sodium phosphate.) Occurs in urine of carnivorous animals. Prepared by adding a slight excess of Na₂CO₂ to H.PO.Aq, and crystallising. (For preparation from bone-ash &c. v. DICTIONARY OF APPLIED CHEMISTRY.)

Colourless, rhombic, prisms; for measurements v. Senarmont, A. Ch. [3] 38, 391. S.G. 1.5235 at 16° (v. Gm.-K. 2, 165); melts at 35° (Kopp, A, 93, 129; v. also Gm.-K. 2, 165); effloresces in air, losing 5H.O.

Solubility in water (Mulder, Gm.-K. 2, 165).

100 pts. water a	issoive Na ₂ HPO ₄ ,
at 0° 2.5 pts.	at 55° 87.7 pts.

50 82.5	100 99-4

Saturated Na.UPO, Aq boils at 105°, and freezes at -45° (Riddorff). S.G. of Na, HPO, Aq at 19° (Schiff, A. 110, 70); 2 p.c. = 1.0083, 4 p.c. = 1.0166, 6 p.c. = 1 · 025, 8 p.c. = 1 · 0332, 10 · p.c. = 1 · 0418, 12 p.c. = 1 · 0503 (p.c. of Na,HPO, 12H,O). 8.6. solution saturated at 15° = 1 · 0469, at 16° = 1 · 0511

(Michel a. Kraft, Stolba, Cim.-K. 2, 166). Loses 12H₁O in vacuo over H₂SO₄, or by heating to 100°; a salt with 7H₂O crystallises from Na₂HPO₄Aq at 33° (Blücher, Mulder, Clark, Gm.-K. 2, 166). For vapour-pressure of watergas when the salt is warmed v. Debray (C. R. 66, 195), Horstmann (A. Suppl. 8, 125), Pfaundler (B. 4, 773). For change of volume on melting v. Wiedemann (W. 17, 561).

Absorbs 11Cl, probably forming NaH2PO, and NaCl (Thomas, C. J. 33, 27). NaJHPO,Aq absorbs CO, (Pagenstecher, J. B. 21, 124; Liebig, A. 64, 349; 79, 112; Heidenhain a. L. Meyer, A. Suppl. 2, 157; Marchand, J. pr. 37, 321). The solution decomposes NH₄Cl (Rose, Gm.-K. 2, 166); boiled with S forms Na₂PO₄Aq with Na.S.O.Aq and Na polysulphides (Filhol a. Senderes, C. R. 94, 649; 95, 343; 96, 1057). remarks on character of reactions of Na HPO Aq with solutions of metallic salts v. Joly, C. R. 103, 1129,

Trisodium diphosphate Na₃H₄P₂O₃xH₂O; by exactly neutralising H₃PO₃Aq by NaOHAq, and

evaporating in vacuo (Filhol a. Senderens, l.c.). Sodium dihydrogen phosphate NaH,PO,H,O; by adding H,PO, to solution of Na,H,P,O, till BaCl2Aq is no longer ppd. (Mitscherlich, Berzelius, Gm. K. 2, 167). A salt with 4H2O was obtained by Joly a. Duffet (C. R. 102, 1391) by cooling a very conc. solution.

Double salts. 1. Sodium ammonium hydrogen orthophosphate Na(NH₁)HPO₁.4H₂O (Microcosmic salt). Occurs in guano. Obtained by dissolving 5 pts. Na₂HPO₄.12H₂O and 2 pts. (NH,),HPO, in water, adding a little NH,Aq, and allowing to crystallise in the cold (Berzelius). Large, clear, monoclinic crystals; S.G. 1.554 (Schiff); very soluble water, solution loses NH₃. The solid effloresces in air, losing all NH, and 4tl₂O, and leaving NaH₂PO₁; when strongly heated leaves Na₄(PO₁)₄. For double sults formed by fusing with metallic oxides v. Wallroth, B. 16, 3059.—2. NaKHPO₁, TH.O (Mitscherlich, Liebig, Schiff, Gm.-K. 2, 167). -3. Na(NH₂),PO₂4H₂O (v. Gm.-K. 2, 220).—4. Na₂(NH₄)PO₂,12H₂O (Herzfeld a. Fouerlein, Fr. 1881. 191).—5. Na₄K₂H₂(PO₁),22H₂O, and Na3(NH,)3H6(PO,)3H2O (Filhol a. Sendereman.C. R. 94, 649; 95, 343; 96, 1057).— 6. 2Na,PO,NaF.xH,O; x=19 and 22 (Baum-

garten, J. 1865, 219; Thorpe, C. J. (2) 10, 660).

Strontium orthophosphates. Normal salt
Sr,P.O., is ppd. by adding Na,PO,Aq or
Na,HPO,Aq + NH,Aq to excess of SrCl,Aq; also by adding cold ammoniacal solution of 90 pts. Na.HPO., 12H.O to 100 pts. SrCl. in Aq (Barthe, C. R. 114, 1267). By pouring SrCl, Aq into Na.PO.Aq at c. 10° gelatinous Sr.P.Q. is formed, but rapidly changes to crystalline SrNaPO., 9H.O (Joly, C. R. 104, 1702.) — Acid salt SrHPO,; by adding Na.HPO,Aq to SrCl.Aq (Skey, C. N. 22, 61; Berzelius, Brott, Wittstein, Gm.-K. 2, 324; Malaguti, A. Ch. [3] 51, 346; Barthe, l.c.). Barthe (l.c.) describes another acid sall, SrH, P.O., XI,O.

Double salts. 1. 3Sr,P₂O_{*}SrCl₂ (Deville s. Carou, A. Ch. [3] 67, 452).—2. SrKPO, (Rose, Weber, Gm.-K. 2, 324).—3. SrNaPO,9H₂O (R. W., Le.; Joly, C. R. 104, 905, 1702).

Thallium orthophosphates. Normal thallous thanks the Theorem 1.

orthophosphate Tl.PO.; by adding H.PO.Aq and

NH₂Aq to TiNO₂Aq, or mixing Tl₂SO₂Aq and Na₂HPO₂Aq with a little NH₂Aq (Crookes, C. N. 3, 193, 303; 7, 290; 8, 169; Lamy, Bl. (2] 4, 193). While silky mass, or needles; insoluble alcohol, easily soluble NH₄ salts (Carstanjen, J. pr. 102, 65, 129). Acid salts.—TiH_PO, and Tl_HPO, xH_O (Lamy, l.c.); according to Ranmelsberg (B. 15, 283) the second of these does not exist. Normal thallic orthophosphate 'TlPO₄.2H₂O, by adding H₃PO₄Aq to Tl(NO₅)₃Aq (Willm, Bl. [2] 2, 89; 5, 354; Strecker, J. pr. 102, 65, 129).

Thorium orthophosphates. Various double salts of Th and K, and Th and Na, are described by Troost and Ouvrard (C. R. 102, 1422; 105,

Tin orthophosphates. The compositions of the stannous salt, obtained by adding Na HPO, Aq to SnCl2 in dilute actic acid, and the stannic salt, by digesting SnO2 with H₃PO₄Aq, are somewhat doubtful (v. Lenssen, A. 114, 113; Reynoso, J. pr. 54, 261; Reissig, A. 98, 339; Girard, C. R. 54, 468). Ouvrard (C. R. 111, 177) describes various double Sn-K and Sn-Na phosphates.

Titanium orthophosphates. Various double salts of Ti and K, and Ti and Na, are described by Ouvrard (C. R. 111, 177).

Uranium orthophosphates. For double U-K and U-Na salts, v. Ouvrard (C. R. 110, 1333). Johnson (B. 22, 976) describes a salt UO, 2P,O5.

Zinc orthophosphates. Normal salt Zun orthopnosphases. Normals sales
Zun P.O., 4H.O.; by ppg. solution of a Zn salt by
Na, HPO, 4q; pp. is gelatinous, but becomes
crystalline. Insoluble water, easily soluble
in acids, NH, 4q, and NH, salts (v. Mischerlich, Gm.-K. 3, 16; Schindler, Mag. Pharm. 26, 62; Debray, Bl. [2] 2, 14; Heintz, A. 143, 356; Graham, A. 29, 23). The acid salt ZnH,P₂O_w2H₂O is obtained in large, triclinic crystals by dissolving ZnO in H, PO, Aq (Demel, B. 11, 1171).

Double salts. 1. With NH, v. Debray (C. R. 59, 40), Bette (A. 15, 129), Heintz (A. 143, 156), Schweikert (A. 145, 57), Rother (A. 143, 356).—2. With Na. v. Schoffer (A. 145, 53), Ouvrard (C. R. 106, 1729).—3. With K, v. Ouvrard (l.c.).

Zirconium orthophosphates. For double alts with K and Na, v. Ouvrard, C. R. 102, 1422; 105, 30.

PYROPHOSPHATES. Salts derived from H.P.O. (For Thiopyrophosphates v. Phosphotic sulphide, Reactions, No. 7, p. 147; and for Sclenopyrophosphates, v. Phosphotic selenide, p. 145.)

Aluminium pyrophosphate Al, (P2O7)3. White amorphous pp. by adding AlCl., Aq to Na, P.O., Aq; soluble NH, Aq, Na, P.O., Aq, and mineral acids (Schwarzenberg, A. 65, 147; Rose, A. 76, 16; Natherical Schwarzenberg, A. 65, 147; Rose, A. 76, 16; Wittstein, Repert. 63, 224). Forms a double salt with Na (Persoz, A. 65, 170; Pahl, Bl. [2] 22, 122).

Ammonium pyrophosphates. Normal salt (NH;),P2O,; by adding excess NH,Aq to H,P,O,Aq and recrystallising from alcohol. Solution boiled gives the acid salt (NH₄)₂H₂P₂O₇ (Schwarzenberg, A. 65, 141).

Barlum pyrophosphate Ba₂P₂O₂.xH₂O. White amorphous solid; by adding Na₁P₂O,Aq to BaCl₂Aq, or H₄P₂O,Aq to BaCAq. Heated in

steam gives off PH₃; gives orthophosphate by heating with alkali carbonates (Hesse, P. 80, 71; Schwarzenberg, l.c.; Birnbaum, Z. [2] 7, 139; Struve, J. pr. 79, 348; Rose, P. 76, 20). Forms

a double salt with Na (Baer, P. 75, 166).

Bismuth pyrophosphate Bi₄(P₂O₇), (Chancel,

C. R. 50, 416).

Cadmium pyrophosphate Cd.P.O., 2H.O (at

100°) (Schwarzenberg, A. 65, 153)

Calcium pyrophosphates Normal Ca2P2O, 4H2O, by adding Na P2O, Aq to CaCl Aq, or CaOAq to H.P.O.Aq; sol. in much Na P.O.Aq. Amorphous, but crystallises from solution in acetic acid or SO₂Aq (Schwarzenberg, A. 65, 145; Rose, P. 76, 16, 20, 230). For action of heat, v. Baer (P. 75, 155). Decomposed by heat, v. Baer (P. 75, 155). Decomposed by water at 280° to H₃PO₄Aq and Ca₄P₂O₈ (Reynoso, C. R. 34, 795). Partially decomposed by boiling with NaOIMq or fusing with alkali carbonate (Rose). The acid salt CaH₂P₂O₂2H₂O is said to be obtained by decomposing the normal salt by a little ILC.O.Aq (Pahl, Bl. [2] 22, 122). Von Knorre a. Oppelt (B. 21, 769) failed to obthis salt, but tain prepared the 2CaH₂P₂O₇.Ca₂P₂O₇.6H₂O by adding CaCl₂Aq to Na₂H₂P₂O₇Aq.

Double salt CaNa, P.O., 4H,O (Baer, P. 75,

Chromium pyrophosphate $\operatorname{Cr}_4(P_2O_7)_3$. reddish green pp. by adding Na,P2O,Aq to Cr alum solution; soluble Na,P2O,Aq, KOHAq, SO2Aq, and mineral acids (Schwarzenberg, A. 65, 149).

Cobalt pyrophosphates. Salts having the composition Co,P,O,, and Co,P,O,, are said to be formed by strongly heating luteo-cobalt phosphate (Braun, Fr. 3, 468; Gm.-K. 3, 463).

Copper pyrophosphates. The normal salt Cu_P2O, 2H2O, by adding Na,P2O Aq (not excess) to Cu salt solutions and drying at 100 q greenishwhite amorphous pp., becoming crystalline by boiling in SO₂Aq; soluble Na₄P₂O₅Aq, NH₅Aq, and mineral acids (Schwarzenberg, A. 65, 156; Stromeyer a. Gladstone, Cim.-K. 3, 615). Forms double salts with NII, K, and Na (v. Schwarzenberg, l.c.; Schiff, A. 123, 1; Persoz, A. Ch. [3] 20, 315; Fletimann a. Henneberg, A. 65, 387).

Iron pyrophosphates. The ferrous salt is obtained by ppg. FeSO, Aq by Na, P2O, Aq; come position not decided (v. Schwarzenberg, A. 65, 153; Struve, J. pr. 79, 318). The ferric salt Fe₄(P₂O₂)₂,9H₂O is a yellowish pp., formed by The ferric salt adding neutral FeCl, Aq to Na, P,O, Aq (acidified FeCl.4q gives FePO, Schwarzenberg). Gladstone (C. J. [2] 5, 435) obtained an allotropic form by heating the ordinary salt in dilute H2SO Aq.

Double salts, with Na (Gladstone, l.c.; Persoz, A. Ch. [3] 20, 315; Fleitmann a. Henneberg, A. 65, 390; Rieckher, N. J. P. 23, 1; Milck,

J. 1865. 263).

Lead pyrophosphate Pb₂P₂O₂. A white amorphous powder; by ppg. Pb(NO₃)₂Aq by Na₄P₂O₂Aq. Obtained in colourless, transparent, rhombic prisms by dissolving PbO in molten KPO, (Ouvrard, C. R. 110, 1333). Soluble ex-2088 of Na,P₂O,Aq, insoluble acetic acid or NH,Aq; decomposed by boiling water (Stromeyer, Schwarzenberg, Gm.-K. 8, 121; Gerhardt, A. Ch. 3] 22, 596). Forms a double salt with Na [Gerhardt, Lc.; Ouvrard, Lc.].

Vol. IV.

Lithium pyrophosphate Li,P.O., 211.O: by adding Na₁P₂O₂Aq to LiClAq, dissolving in acctic acid, and ppg. by alcohol (Rammelsberg, B. B. 1883. 18; Merling, J. 1879. 1043). A double salt, Li₃NaP₂O₄, is formed in prismatic crystals by dissolving Li₂CO₃ in molten NaPO₄ (Ouvrard, C. R. 110, 1333).

Magnesium pyrophosphates. The normal salt Mg.P₂O.,3H₂O is formed by adding MgSO₄Aq to Na.P₂O.,Aq (Rose, P. 76, 16, 20), or by dissolving MgO in Na.H₂P₂O.Aq and heating (Schwarzenberg, Gm.-K. 2, 448). Pp. becomes crystalline by remaining under liquid from which it has been not Perpa. Z. (21, 6, 305) which it has been ppd. (Popp, Z. [2] 6, 305), also by boiling with SO Aq (Schwarzenberg, la.). The salt is obtained, without HO, by strongly heating MgNH,PO, Loses 3H O at 100°; fused with soda or heated with cone. ILSO, gives Mg,P.O. (lose; Weber, P. 73, 137). Easily soluble UClAq and HNO,Aq; ppd. incompletely by NH,Aq (Freschins; Weber). An acid salt, MggH2P2O,, combined with NO, is said to be formed by evaporating to dryness with HNO, Aq (Luck, Fr. 13, 255; Campbell, P. M. [4] 21, 380). Forms a double salt with Na (Persoz, A. 65, 169; Schwarzenberg, A. 65, 146; Beer, P. 75, 168).

Manganese pyrophosphates. The normal manganous salt Mn.P.O. 3H.O is a white amorphous powder; by ppg. a salt of Mn by Na, P.O, Aq (Schwarzenberg, A. 65, 133). Soluble Na₁P₂O,Λq (Pahl, Bl.,[2] 22, 122). Loses one H₂O at 120° (S., l.c.). The salt without H₂O is formed by strongly heating the hydrated salt, or MuHPO, 3H O, or MuNH, PO, HO (S., Le.; Heintz, &c., Gm.-K. 2, 475); white powder, S.G. 3.5847 at 20° (Lewis, Am. S. [3] 14, 281); heated to whiteness in H gives $Mn_3P_2O_8$; reduced by charcoal to Mn phosphide (Struve, J. 1860. 78). The acid salt MnH₂P₂O₇4H₂O is said to be formed by action of oxalic acid on the normal salt (Pahl, l.c.). Various double salts are described with K (Pahl, l.c.; Schjerning, J. pr. [2] 45, 515); with Na (Pahl, Rose; Christensen, J. pr. [2] 34, 41); with Na and NH, (v. Otto, J. pr. 2, 418). The acid manganio salt MnHP O, is said to be formed by heating MnPO, with H, PO, Aq to 170 - 190° (Chrir ansen, J. pr. [2] 28, 1).

Mercury pyrophosphates. The normal mercurous salt Hg,P,O,H,O is a heavy white powder obtained by adding Na, P.O, Aq to HgNO, Aq (Rose, Gm.-K. 3, 754; Schwarzenberg, A. 65, 183). The normal mercuric sall, Hg₂P₂O₃, is obtained by adding Na₁P₂O₃Aq to Hg(NO₃)₂Aq (S., I.c.; Reynoso, C. R. 34, 795).

Nickel pyrophosphate Ni P2O, A green pp. by adding Na, P2O, Aq to NiSO, Aq; soluble excess Na, P2O, Aq, NII, Aq, and acids; obtained crystalline by boiling with SOAq; decomposed by water at 280°-300° (S., l.c.; Reynoso, l.c.).

Potassium pyrophe sphates. The normal salt. K,P,O,xH,O, is obtained by strongly heating KHPO; also formed by reaction of POCl, with KOHAq (Gladstone, C. J. [2] 5, 435). Loses one H₂O at 100°, and is dehydrated at 300°. Solution in water does not change to K, HPO, on boiling (Schwarzenberg), nor on evaporation (Gladstone), but change is effected by heating to 280° (Reynoso, C. R. 34, 795); boiling with KOHAq produces the ortho-salt. The acid salt, K₂H₂P₂O₂,

acid and alcohol, and evaporating over H2SO4 (Schwarzenberg, λ . 65, 137). Forms a double salt with $2K_2(NH_4)HP_2O_2H_2O$ (S., l.c.); also with $Cr_2H_4(P_2O_2)_2$ (Schjerning, J.pr. [2] 45, 515).

Silver pyrophosphates. Normal salt, Ag, P,O,; a white pp. from AgNO, Aq and Na, P2O, Aq (Clark, Stromeyer, Gm.-K.3, 919). S.G. 5:306 at 7:5'; soluble NII, Aq, reppd. by HNO, Aq; boiled with Na, HPO, Aq gives Ag, PO, Heated with II, PO, Aq at 180° gives the acid salt Ag, H, P,O, (Hurtzig a. Glavthey, A, 111, 120). Geuther, A. 111, 160).

Sodium pyrophosphates. The normal salt, Na₁P₂O₂, is formed by strongly heating Na₂HPO₄; a glass-like solid, becoming opaque on cooling (Clark, N. Ed. P. J. 7, 298); gives Na, PO, and PH₃ when heated in H (Struve, J. pr. 79, 350); heated with NH Cl gives NaCl, NaPO,, and PCl, (Rose). The hydrated salt, Na₄P₂O_{.10}H₂O, erystallises from Na₄P₂O_{.4}Q (Clark, l_e,; von Blücher, P. 50, 542) in monocline crystals (Rammelsberg; Haidinger, P. 16, 510; Handl, W. A.B. 32, 250; Schaechi, P. 109, 365; Duffet, C. R. 102, 1327). Crystallises unchanged from Aq with NH₄ or NH₅Cl added. Solution boiled with acids gives Na₂PO₄Aq. Poggiale (J. Ph. [3] 44, 273) gives solubility; 100 parts water dissolve—

~	Na P.O.	Na_P_0,10H_0

100	40.26	93:11

The acid salt Na₂H₂P₂O₂; by heating NaH₂PO₄ to 190° - 204° (Graham, Gm-K. 2, 169), or by addition of alcohol to an acetic acid solution of Na₄P₂O₇ (Schwarzenberg, A. 65, 139). Crystallises from aqueous solution with 6H,O (Bayer, J. pr. 106, 501; Rammelsberg, B. 16, 21; Duffet, C. R. 102, 1327). When strongly heated gives Ta, H,P,O, (Fleitmann a. Henneberg, A. 65, 328).

Double salts.—1. Na.(NH.), P.O., xH.O., x=5 or 6 (Schwarzenberg, A. 65, 140, 142; Rammelsberg).—2. Na.K., P.O., 12H.O., and Na.P.O., Na.H.P.O., 2H.O. (S., Le.; R., Le.). Wall-salt (H.) 20, 20, 214, Na. (S., Le.; R., Le.). roth (Bl. [2] 39, 316) has described double salts with pyrophosphates of Al, Be, Bi, Cd, Ca, Ce, Cr, Co, Cu, Di, Er, La, Mn, Mg, Ni, Th, Yb, Y, Zn, and Zr. For double salts with pyrophosphates of Sn and Ti v. Wunder, J. 1870. 359; 1871. 323. Na, P.O, seems to combine with B₂O₃ by fusing Na₄P₂O₇ with boric acid (Prinvault, C. R. 74, 1219).

Strontium pyrophosphate, Sr.P.O, orystalline powder; from Sr(NO₃),Aq and Na₄P₂O,Aq; also by heating SrHPO₄ (S., Lc.). Forms acid salts (von Knorre a. Oppelt, B. 21, 769); also a double salt with Na (Baer, P. 75, 166).

Thallium pyrophosphates. Normal thallous salt, Tl.P.O.; by heating Tl.HPO. (Descloizeaux, 4. Ch. [4] 17, 329). S.G. 6.786. Crystallises Johnson, B. 22, 976).

is obtained by treating the normal with acetic | from aqueous solution with 2H.O (D., I.c.). The acid salt Tl₂H₂P₂O₇,H₂O is formed by heating TlH₂PO₈ to 250³-275⁵ (Lamy, Rammelsberg, Gm.-K. 3, 177).

Thorium pyrophosphates. Double salts with K and Na are described by Ouvrard (C. R. 105, 30).

Uranium pyrophosphates. Double salts with K and Na are described by Ouvrard (C. R. 110, 1333).

*Yttrium pyrophosphate. Johnson describes Y₄(P₂O₇)₃, formed by heating Y₂3SO₄ with HPO₃ to 316° (B. 22, 936).

Zine pyrophosphate, Zn,P,O,. By ppg. Zn salts by Na,P,O, (Stromeyer, Am.-K. 2, 832; Gladstone, ibid. 3, 16; Schwarzenberg). Forms a double salt with NH, (Bette, A. 15, 129).

Zirconium pyrophosphates. Double salts with K and Na are described by Ouvrard (C. R.

METAPHOSPHATES. Salts derived from HPO. The general methods of preparation, properties, and reactions of the metaphosphates are described at the beginning of this article (p. 106); the divisions into mono-, di-, tri-, tetra-, and hexa- metaph sphates, with the processes by which typical salts of each division are prepared, have also been described already (p. 107). It will suffice here to enumerate the salts, with an indication in each case to which division the salt is assigned by Maddrell, Fleitmann a. Henneberg (cf. Tammann's results regarding Na, di-, and tri- metaphosphates p. 107). T.'s paper in J. pr. [2] 45, 417 should also be consulted.

Aluminium dimetaphosphate, AlaPaO18. By dissolving Al2O2xH2O in H2PO1Aq, evaporating. and heating to 316° (Maddrell, C. S. Mem. 3. 373; Johnson, B. 22, 976). For hexa- salt v. T.,

373; Johnson, B. 22, 976). For hexa-salt v. T., J. pr. [2] 45, 417.

Ammonium metaphosphates. (MI₁),P₂O₃, from Cu salt by (NI₁),SAq; at 200° 250° becomes mono-salt (NH₂)PO₃ (Fleitmann, A. 72, 236). For decta-and penta-salts v. T. l.c.

Barium metaphosphates. (1)? Mono-salt BaP₂O₄; by heating BaCO₂ with H₂PO₁ to 316° (M. l.c.; F., l.c.; Rose, P. 76, 5; Birnbaum, Z. [2] 7, 139). (2) Di-salt, Ba₂P₁O₁₂-sH₂O; from Na ort NH₄ salt* and BaCl₂Aq (F., l.c.). (3) Trisalt, Ba₂P₂O₁₈-sH₂O; from Na salt and BaCl₂Aq (F. a. Henneberg, A. 65, 313). (4) Hexa-salt; (F. a. Henneberg, A. 65, 313). (4) Hexa-salt; from Na salt and BaCl₂Aq (Rose; Graham, P.

Bismuth metaphosphate. ? Tetra- salt; by Insing H.PO₄ with Bi.O₄.» H.O (F., l.c.); HPO₃Aq, Bi.NO₃ solution and NH₂Aq give a pp. (Persoz, Gm. K. 2, 832).

Cadmium metaphosphate. ? Tetra- salt (F., l.c.; Persoz, Gm.-K. 3, 54). Double s with Na and K (Ouvrard, C. R. 106, 1729). Double salts

Calcium metaphosphates. A salt is obtained by heating CaHPO,; for action of HPO, on CaCO, v. Rose (P. 76, 5), Liebig (A. 11, 262); Dissilt, Ca,P,O,,xH,O; from Na salt and CaClAq (M., l.c.; F., l.c.). Double salts.—CaAm,P,O,,x2H,O (F., l.c.); CaNaP,O, (F. a. H.,

Chromium dimetaphosphate, Cr.P.O.s. By heating CrO.H. with H.PO. to 316° (M., Lc.; Hautefeuille a. Margottet, C. R. 96, 849, 1042;

Cobalt metaphosphates. ? Mono- salt ! CoP2O4; by evaporating CoSO4 with H3PO4Aq, and heating to 316° (M., l.c.; H. a. M., l.c.). Di- salt Co.P.O.; by heating roseo-cobaltic phosphate (Braun, Ammon. Kobaltverbindungen [Göttingen, 1862]). ? In xa-salt Co. P. 10. in the Col. Aq and the Na salt (Rose). Ohto-salt (T., Le.). Double salt with Na (M., Le.).

Copper metaphosphates. Dissult Cu.P.O.; by heating CuO or Cu(NO3)2 with H3PO4 to 3160 of cally of the state of the st

NH, and Na (F., l.c.; T., l.c.).

Iron metaphosphate. Di-ferric salt Fe P.O. by heating FeCl, with H.PO, to 316° (M., l.c.; H. a. M., l.c.; Johnson, B. 22, 976).

Lithium bexametaphosphate. A double salt Li Na, P.O., is described by Tammann (l.c.).

Lead metaphosphates. Di- salt Pb.P.O.; from $Pb(NO_3)_*Aq$ and the Na salt; also by heating H_3PO_4 and $PbO(F_1, Lc.)$. Tri-salt $Pb_1P_0I_{3,1}$ from the Na salt and $Pb(NO_3)_*Aq(F, a. H., Lc.)$. Deka-salt, T. (l.c.). Double salt PhAm. P.O. (F., l.c.).

Magnesium metaphosphates. ? Mono- salt MgP₂O₆, by heating MgO with H₃PO₄ (M., l.e.). Di-salt Mg₂P₄O₁₂xH₂O; and tri-salt Mg,PaO1,xH2O; from the corresponding Na salt and MgCl2Aq (F., l.c.). Hexa-salt Mg, P12O ... (Graham, Gm. K. 2, 214). Double sults, with NH, and Na, v. F. (l.c.); F. a. H. (l.c.); M. (l.c.); Graham (l.c.); Ouvrard (C. R. 106, 1729); Tammann (l.c.).

Manganese metaphosphates. manganese metaphosphates. 11. sate Mn.P.O.; by heating a Mn salt with H.PO, to 316° (M., Le.; F., Le.); with 8H.O. by ppg. (NH.).P.Q. Aq by excess of MnCl.Aq (F., Le.). Tri-salt Mn.P.O.; H1H.O; from MnCl.Aq (not MnSO₄) and Na.P.O.; Hexa-salt Mn.P.O.; by using Na P₂O₂ (Otto, Rose, Gm. K. 2, 490; Braun, I.c.). Deha-salt Mn₁₀P₂₀O₄₀ (Tammann, J. pr. [2] 45, 417). Double salts, with NII and Na (v. F., l.c.; Rose, l.c.; T., l.c.).

Mercury metaphosphates. White pps, are formed by adding Na tri- and hexa- metaphosphate to $Hg(NO_3)_2\Lambda q$ (F. a. H., l.c.; Rose, Gm., K.

2, 754).

Nickel metaphosphates. Di-salt Ni₂P₄O₁₂; by heating Ni O3 with H3PO4 to 316° (M., l.c.; 11. a. M., l.c.). Hexa-salt Ni P12O16; by adding NiCl Aq to Na P.O. (Rose). Double salt with Na

(M., l.c.).

metaphosphates. Potassinm Mono- salt KPO,; by heating KH,PO, to full redness (M., l.c.; Graham, Darracq, Gm.-K. 2, 32). S.G. 2.2639 at 14.5° (Clarke, Am. S. (3] 14, 281). Disalt K,P,O,; by treating the Cu salt with K.SAq (F., l.c.). Hexa-salt K,P,O,; (T., l.c.). Double all with NH, (F., l.c.). Compound with BO, salt with NH, (F. 9l.c.). C (Prinvault, C. R. 74, 1249).

Silver metaphosphates. Di-salt Ag₂P₂O₀; and tri-salt Ag₃P₃O₉; from AgNO₃Aq and the corresponding Na salts (F., l.c.; F. a. H., l.e.). Heza-salt Ag, P₀()₁; from Ag, NO, heated with H₂PO, to 316³, or by adding Na₅P₂O_{1,8}Aq to AgNO,Aq (Grsham; F., Lc.; T., Lc.; Rose, Berzelius). Double salts with Al, Cr, and Fe (H. a. M., l.c.).

Sodium metaphosphates. For conditions of formation and general reactions v. p. 106. The following salts have been described: Mono- salt NaPO, (F., l.c.; M., l.c.; F. a. H., l.c.; Graham, Gm.-K. 2, 170; Jamieson, A. 59, 350; Müller. P. 127, 428); di- salt Na, P.O., 2H.O (F., l.c.); tri-salt Na, P,O, 6H,O (F. a. H., l.c.); tetra-salt Na₁P₄O₁₂ (F., l.c.); hexa-salt Na₆P₆O₁₈ (F., l.c.; T., l.c.; G., l.c.). For double salts with Na and NH , v. F. (l.c.).

Strontium metaphosphates. ? Mono- salt SrP.O.; by heating SrCO, with HaPO, (M., l.c.; ct. Rose, F. 76, 8; Scheerer, J. pr. 75, 113). For

a deka- sait, r. T. (l.c.).

Thallium metaphosphate. TIPO₃ said to exist in two forms, one insoluble in water (? disalt), and the other soluble (hamy, Gm.-K. 2, 177).

Thorium metaphosphate ThP4O12 (? di-salt, Th₂P₈O₂₁); by heating Th(SO₄)₂ with H₃PO₄ to redness (Johnson B. 22, 976). For deable salts with K and Na, v. Troost a. Ouvrard (C. R. 105, 30).

Uranium metaphosphate. Di-sall U2P8O18 (H. a. M., l.c.).

Zine metaphosphates. Di- salt Zn2P4O12; by heating ZnO with H,PO, to 350° (F., Lc.); with 4H2O by adding ZnCl2Aq to (NH1) P.O.Aq. For double satts with NH, and Na, v. F. a. H. (l.c.); Bette (A. 15, 129).

TETRAPHOSPHATES and DEKAPHOS-PHATES. Salts of the hypothetical acids H.P.O. and H.P.O. (v. pp. 106, 107).

Barium tetraphosphate Ba,P,O,, A heavy crystalline powder; by fusing Na,P,O,, with BaCl. (F. a. H., A. 65, 313).

Magnesium tetraphosphate Mg_1P_iO_15. pared similarly to the Ba salt (F. a. II., L.c.).

Silver tetraphosphate Ag_aP₄O₁₃. From the Na salt and AgNO₂Aq (Berzelius, P. 19, 331).

Sodium tetraphosphate Na,P,O,, fusing Na₆P₆O₁₈ with Na₄P₂O₇ or Na₃PO₄ (F. a. H., l.c.; Uelsmann, A. 118, 101).

Silver dekaphosphate Silver dekaphosphate $Ag_{12}P_{10}O_{31}$. From the Na salt and $AgNO_4Aq$ (F. a. H., l.c.; U., l.c.).

Sodium dekaphosphate Na₁₂P₁₀O₃₁. A glassy mass; by fusing Na, PoO18 and Na, PoO 2(F. a. II., l.c.). M. M. P. M.

PHOSPHENYL CHLORIDE v. PHENYL-di. chloro-phosphene.

PHOSPHENYLIC ACID v. PHENYL PHOS-PHITES

PHOSPHENYLOUS ACID Call PHO.OH. Benzene phosphinic acid. [70]. S. 7-23 in the PHOSPHENYLOUS ACID cold; 211 at 100°. Formed by adding water to Coll PCl2, and boiling (Michaelis, A. 181, 303; B. 10, 816). Leaflets, v. sol. alcohol. Decom. posed by heat into phenyl-phosphine, benzene, posed by heat into pnenyt-pnospnine, benzene, and HPO₃. PCl₅ forms C₆H₃PCl₂.—KA' 2aq.—SH₄A'. BaA', 4aq.—PbA'₂: amorphous pp.

Ethyl ether EtA'. Oil.

Diethyl ether C₆H₃P(OEt). (235°).

Formed from C₈H₂PCl₂ and NaOEt. Liquid with

very powerful odour.

PHOSPHIDES. Compounds of P with one other more positive element. The chief phos phides are those of Al, Sb, As, Ba, Be, Bi, Cd, Ca, Cu, Cr, Au, H, Fe, Pb, Mg, Mn, Hg, Mo, Ni, K, Pt, Ag, Na, Th, Sn, Tl, W, Zn, Zr. (Phos-

phides of H are described as Phosphorus hydrides | order to decompose the compound of the phosunder Phosphorus.) Many phosphides are formed by heating together P and the more positive element in an atmosphere of CO2 or N; phosphides are also produced by heating P with several metallic oxides or with salts in solution; also by heating metals or their oxides in PH, Phosphides are generally brittle solids; many react with water or dilute acids, evolving P hydrides; some yield basic phosphates when heated in air. For descriptions of the different phosphides v. the individual elements.

M. M. P. M.

PHOSPHINE. PH is sometimes known by this name, v. Phosphorus, hydrides or, p. 135. PHOSPHINES are the phosphorus analogues of amines, and result from the replacement of hydrogen in phosphuretted hydrogen by alkyl radicles. They may be classified, like the amines, into primary, secondary, and tertiary bases, and, in addition, quaternary compaunds are known analogous to the salts of compound ammoniums.

Methods of preparation. 1. Action of the haloid derivatives of hydrocarbon radicles on metallic phosphides. It was by this reaction that Paul Thénard (C. R. 21, 141; 25, 892) discovered the first members of the phosphine group in 1843-47. He experimented with methyl emoride and calcium phosphide, and apparently isolated trimethyl-phosphine, (CH₃)₂P₄ as an inert solid, and a substance (CH₃)₄P₂ analogous to cacodyl as a spontaneously inflammable liquid, boiling at 250°, very explosive, poisonous, and Thénard recognised the relationship unstable. of trimethyl-phosphine to ammonia, and predicted the existence of the then undiscovered organic compounds of nitrogen and antimony.

In 1855 Hofmann a. Cahours (T. 1857; A. Ch. [3] 61, 5) investigated the action of methyl iodide on sodium phosphide, and obtained tetramethyl-phosphonium iodide in addition to trimethyl-phosphine and the phosphorised encodyl of Thénard. They found that the method was dangerous, and furnished mixtures the separation of which presented enormous difficulties.

Berld (J. pr. 66, 73) about the same time obtained very small quantities of triethyl-phosphine by the action at a very high temperature of ethyl iodide on sodium phosphide obtained by heating sodium and phosphorus together in rock oil.

Cahours in 1859 (C. R. 49, 87; J. 1859, 430) prepared tetrethyl-phosphonium iodide by the action of ethyl iodide on crystallised zinc phosphide (obtained by heating the metal in phosphorus vapour at 180°).

In 1882 Letts a. N. Collie (Tr. E. 30 pt. i. 181) investigated the action of benzyl chloride on sodium phosphide, and found that tetra-benzylphosphonium chloride was produced in abundance.

2. Action of organo-metallic bodies on tri-chloride of phosphorus. The action of zine alkyls on phosphorus trichloride was first investigated by Hofmann a. Cahours (A. Ch. [3] 51), and was further studied by Hofmann (A. Ch. [3] 62; 63 · 64). By this method tertiary phosphines are exclusively formed: 3R.Zn + 2PCl. = 2R₃P + 3ZnCl₂. It is necessary to treat the product of the reaction with caustic potash, in

phine with zinc chloride. By this reaction Hofmann a. Cahours obtained PMc, and PEt, and showed that they resemble the corresponding amines in many respects, especially in the readiness with which they combine with alkyl iodides to give quaternary compounds. On the other hand, they proved that, unlike the amines, tertiary phosphines readily combine with oxygen to give very stable compounds of the general formula R,PO.

3. Action of alcohols on phosphonium iodide; and Action of alkyl iodides on phosphonium iodide and exide of zinc (Hofmann's methods). In the year 1871 Hofmann again took up the study of the phosphines (B. 4, 205), and by the action of alkyl iodides on phosphuretted hydrogen obtained not only tertiary and quaternary compounds, but also primary and secondary bases. Hofmann took advantage of the fact that phosphonium iodide when heated with alcohol yields phosphuretted hydrogen, ethyl iodide, and water. When phosphonium iodide (1 mol.) is heated with alcohol (3 mols.) for 8 hours at 180, the crystalline product is a mixture of PEt.HI and PEt.I. and, on addition of caustic soda, friethyl-pho-phine separates as a clear liquid, while the solution gives, on evaporating, beautiful crystals of tetrethylphosphonium iodide. If the tubes are heated for four hours only, two layers of liquid are visible on cooling, and the tubes show great pressure when opened. It may be taken for granted, then, that the reaction occurs in two phases, in the first of which Etl is liberated, which then acts upon PH, in the same way as it acts on ammonia. Hofmann employed this method successfully in the methyl (B. 4, 209), ethyl (B. 4, 205), propyl (B. 6, 292), butyl (B. 6, 296), and amyl (B. 6, 297) series. Hofmann (B. 4, 372) endeavoured to prepare the primary and secondary bases according to the equations:

 $PH_{1}I + C_{1}H_{2}O = C_{2}H_{2}PII_{2}M + H_{2}O$ $PH_{1}I + 2C_{1}H_{2}O = (C_{2}H_{2})_{2}PIIIM + 2H_{2}O_{2}$ by altering the proportions of phosphonium . iodide and alcohol, but without success, the tertiary base being produced alone or mixed with the quaternary compound, while with the proportions required for the second equation the tubes invariably exploded.

In the meantime Orechsel a. Finkenstein (B. 4.352) believed that they had succeeded in obtaining the primary bases by saturating EtI or MeI with PH, and allowing the solutions to remain for some time at the ordinary temperature, or by heating them at 100°, and also by heating an ethereal solution of ZnI. saturated with PH, together with MeI. Hofmann (B. 4, 372) repeated these experiments, and showed that only tertiary and quaternary derivatives were formed. The idea then occurred to him of heating the alkyl iodide with phosphonium iodide ein presence of a metallic oxide, with the happiest results; for on heating a mixture of phosphonium iodide (2 mols.) with ethyl iodide (2 mols.) and zine oxide (1 mol.) in scaled tubes at 150° for from six to eight hours, a complete reaction occurred. the tubes when cold containing a crystalline mass consisting exclusively of the hydriodates of the primary and secondary bases, the former being the chief product, while the latter was only

formed in small quantities. The addition of water to the product of the reaction liberated the primary phosphine alone, which was distilled off in a hydrogen atmosphere, while the secondary phosphine was subsequently set at liberty by the action of an alkali. By means of this general method Homann prepared methyl (B. 4, 430), ethyl (B. 4, 605), propyl (B. 6, 292), butyl (B. 6, 296), amyl (B. 6, 297), and benzyl

(B. 5, 100) phosphines.
4. Michaelis's methods. methods, although of excellent service for obtaining the phosphines of those radicles which form alcohols, could not be employed in the preparation of phosphines containing purely arounatic radicles (B. 5, 100). Michaelis, on the other hand, not only succeeded is obtaining all the phenyl-phesphines, but also in discovering a fairly general method for the production of primary phosphines. The substance forming the starting-point for the preparation of phosphines by these methods is trichloride of phosphorus. One atom of chlorine is first replaced in that body by one or other of the following processes :-

(a) The mixed vapours of a hydrocarbon and the trichloride are repeatedly passed through a red-hot tube. Thus when benzene is employed 'phosphenyl' chloride is obtained: $PCl_3 + C_9H_6 = (C_6H_5)PCl_2 + HCl$.

(a) A mercury alkyl is heated with the trichloride under pressure : PCl, + (C, H,), Hg

 $= (C.H.)PCl_0 + Hg(C_0H_1)Cl_1$

(c) By digesting a hydrocarbon with the trichloride and aluminum chloride, the reaction being the same as (1). Other substances besides hydrocarbons—yield—substituted—phosphorus chlorides when submitted to this reaction. Thus a mixture of acctone, PCl3, and aluminium chloride react spontaneously, according to the equation:

2(CH₃)₂CO + PCl₃ - 2HCl + (CH₃ CO.CH₃)₂PCl.

By means of these different reactions Michaelis and his pupils have obtained a considerable number of substituted phosphorus chlorides, among which are: Phenyl phosphoruschloride by methods 1, 2, and 3 (B. 6 [1873], 601; 8 [1875], 922; 12 [1870], 1009). Tolyl phose phorus-chloride by method 3 (B. 13, 653). Xylyl phosphorus-chloride by method 3 (A. 212, 203, 209). Ethyl phosphorus-chloride by method 2 (B. 13, 2174). Propyl phosphorus-chloride by method 2 (B. 13, 2174). Naphthyl phosphorus-chloride by method. 2 (B. 9, 1051). Acctonyl phosphorus-chloride by method 3 (B. 17, 1273). The substituted chlorides resemble PCl₃ in properties. As a rule they are fuming liquids, combining readily with chlorine to give solid compounds analogous to pentachloride of phosphorus; treated with water, they yield phosphinous (phosphinic) acids. Thus phenyl phosphorus-chloride gives phenyl phosphinous (benzene phosphinic) acid: $(C, H_3)PCL_+ 2H_2O = (C, H_3)PH_2O_2 + 2HCl$. The products of addition which they form with oblorine react with water to give phosphinic (phosphonic) acids: (C₄H₃)PCl₄+3H₂O = (C₄H₃)PH₂O₂+4HCl. Michaelis was unable to obtain more than mere traces of the primary phosphine by the action of nascont hydrogen on the substituted chlorides. When gaseous HI is passed into the chloride,

chlorine is gradually displaced by iodine; $C_6H_3PCl_2+3HI=C_8H_3P1_2HI+2HCl$. From this iodide Michaelis obtained phenyl-phosphine by the action of alcohol: $3C_aH_1PI_2HI + 9C_2H_aO$ = $C_aH_3PII_1 + 2C_6H_3PO_3H_2 + 3H_aO + 9C_2H_3I$. In later experiments he employed a simpler method, namely the destructive distillation of the phosphinous (phosphinic) acid which, as already stated, is produced by the action of water or alcohol on the substituted chloride: 30, H.PO, H. = C.H.PH. + 2C.H.PO.H. From phenyl phosphorus chloride Michaelis obtained diphenylphosphine by the following reactions: (1) The chlorido is digested with mercury diphenyl at

 $(\mathbf{C}_{\mathbf{a}}\mathbf{H}_{\mathbf{a}})\mathbf{PCl}_{\mathbf{a}} + \mathbf{Hg}(\mathbf{C}_{\mathbf{a}}\mathbf{H}_{\mathbf{a}})_{\mathbf{a}} = (\mathbf{C}_{\mathbf{b}}\mathbf{H}_{\mathbf{a}})_{\mathbf{a}}\mathbf{PCl} + \mathbf{HgCl}(\mathbf{C}_{\mathbf{a}}\mathbf{H}_{\mathbf{a}})$ (B. 8, 1304); or it is heated for some time at 280', when the following reaction occurs: $H(C_0H_5)PCl_2 = (C_0H_5)_2PCl + PCl_3$.

(2) Diphenyl phosphorus chloride when heated with water or dilute soda solution decomposes in the following manner: 2(C, H,),PCI+2H,O $= (C_n H_s)_2 PH + (C_n H_s)_2 HPO_s + 2HCl$ (Michaelis a. Gleichaffan, B. 15, 801). He also obtained the tertiary base; at first by acting upon a mixture of phenyl-phosphorus chloride and bromo benzene with sodium: (C,H,)PCl, +2C,H,Br+3Na

2NaCl+NaBr+(CH,),P, but later this method was modified in a remarkable way, by substituting for phenyl phosphorus chloride, phosphorus chloride alone, the reaction occurring quite easily and very energetically at ordinary temperatures according to the equation:

 $P(T_a + 3(C_aH_a)Br + 6Na = 3NaCl + 3NaBr + (C_aH_a)_aP_a$

5. Action of alcohols on a mixture of phos-phoras and phosphorus iodide. Letts a. Blake (Tr. E. pt. 2) have shown that very remarkable reactions occur when benzyl alcohol acts upon a mixture of phosphorus and phosphorus iodide (in the proportions employed for obtaining phosphonium iodide by the action of water), whereby a number of the phosphorus derivatives of benzyl are obtained. The action occurs spontaneously at ordinary temperatures, and, although its mechanism was found difficult to investigate, the following equations account for the formation of the different products:-

(1) $PI_2 + C_7H_7OH + H_2O = (C_7H_7)H_2PO_2 + HI + I$ (2) $PI_2 + C_1H_1OH + 2H_2O + I = (C_1H_1)H_2PO_3 + 3HI$ (3) $PI_2 + 2C_1H_1OH = (C_1H_1)_2HPO_2 + HII + I$ (1) $PI_2 + 3C_1H_2OH + HII = (C_1H_1)_2PO + 2H_2O + 3I$ (5) $PI_2 + 4CHOH + 4HI = (CH_1)_1PI + 4H_2O + 5I$ (6) PI₂ + 2H O (7) PI₂ + 4H O + 3I $= H_3PO_2 + HI + I$ = $H_3PO_4 + 5HI$ (S) 2HI + C, H, OH $= \mathbf{C} \mathbf{H}_n + \mathbf{H}_2 \mathbf{O} + \mathbf{I}_2$ (9) P + L2 = PL

All the products indicated by the above equations were obtaine in quantity, especially benzyl phosphinic acid, di-benzyl phosphinic acid, and tri-benzyl phosphine oxide, and the method is un loubtedly the easiest and best for the preparation of those substances. Whether other alcohols behave in a similar manner to benzyl alcohol with a mixture of phosphorus and its iodide has not yet been ascertained.

General proporties of the primary phosphines. The following primary bases have been obtained;

 Hofmann, B. 6, 296,
 Moslinger, B. 9, 1005,

- Hofmann, B. 4, 209. Hofmann, B. 6, 292. Hofmann, B. 6, 297. Michaelis, B. 7, 6, 1688. Hofmann, B. 5, 100; Let's a, Elske, Tr. E. 35 pt. 2. Michaelis a, Panek, A. 212, 233.

Most of the primary bases are liquids, insoluble in water, but soluble in ether. They fume in the air, and grow very hot, their vapour igniting spontaneously at times. The products of this oxidation appear to have been investigated only acid when boiled with water is decomposed, in a few cases, and chiefly in the aromatic series. Phenyl phosphine (Michaelis, B. 10, 807) and tolyl phosphine (Michaelis a. Panek, 1, 212, 234) both absorb a molecule of oxygen, and are converted into phosphinous (phosphinic) acids, which are monobasic, and therefore probably have the constitution RPH(OH):O. These acids are readily decomposed by heat, giving the primary phosphine, and the corresponding phosphinic (phosphonic) acid 3RPH2O2 RPH2 + 2RPH2O3 a reaction analogous to that which gives rise to phosphoretted hydrogen and phosphoric acid when hypophosphorous and phosphorous acids are heated. Letts and Blake (Tr. E. 35, pt. 2) find that benzyl phosphine yields a mixture of benzyl phosphinous (phosphinic) and benzyl phosphinic (phosphonic) acids with some phosphoric acid. Submitted to the action of strong nitric acid, many of the primary phosphines (and probably all) absorb three atoms of oxygen, and are converted into phosphinic (phosphonic) acids. This has been shown by Hofmann (B. 5, 110) to be the case in the methyl, ethyl, isopropyl, isobutyl, and isoamyl series.

The phosphinic acids are solid substances, which, with the lower members of the fatty series, can be distilled unchanged (Hofmann, B. 6, 303). But in some other instances a different reaction occurs: thus phenyl phosphinic (benzene phosphonic) acid when heated slowly to 200° gives a pyro-acid, while when rapidly heated to 250° it decomposes into benzene and metaphosphoric acid: $C_aH_aPH_2O_3 = C_6H_6 + HPO_3$. The phosphinic (phosphinic) phonic) acids are all dibasic, and no doubt have the structure RPO(OH). All the primary phosphines have distinct alkaline properties. They combine readily with hydracids forming crystalline compounds, which can, as a rule, be volatilised (with dissociation more or less complete), and which resemble the compounds of phosphoretted hydrogen in being instantly decomposed by water with liberation of the phosphine. The hydrochlorides combine with chloride of platinum to give chloroplatinates. The salts of the primary bases with oxyacids have been scarcely at all investigated. The action of halogens on primary phosphines has not been sufficiently investigated.

phosphine take fire when they come in contact with chlorine or bromine (Hofmann, B. 4, 433, 609). Benzyl-phosphine yields with bromine a mixture of its own hydrobromide and substitu-tion-products (Letts a. Blake, Tr. E. 35, pt. 2). Sulphur acts on the primary bases. With

the methyl and ethyl derivatives, compounds have been obtained but not investigated (Hofmann, B. 4, 433, 610). With phenyl phosphine sulphur acts slowly in the cold, rapidly at a high temperature (Michaelis, B. 10, 810). Two substances are produced, one, a thick liquid, soluble in other, having the composition (C,H,)PH2S, the other a crystalline product to which Michaelis assigns the formula $(C_oH,P)_aS$. The first of these bodies decomposes when heated in the following Anner:

2C, H, PH, S = C, H, PS + C, H, PH, + H, S, When benzyl phosphine is warmed with sulphur

the following reaction occurs (Letts a. Blake, l.c.): $2C_1H_1PH_2 + 6S = (C_1H_2)_2P_2S_1H_2 + H_2S$ and the resulting pyro-benzyl-thiophosphinic

yielding mono-thio-benzyl phosphinic acid: $(C_2H_2)_2P_2S_3H_2+4H_2O=2C_3H_2PS(OH)_2+3H_2S_4$ In view of the analogies existing between nitrogen and phosphorus, considerable interest is attached to the action of carbonyl chloride and bisulphide of carbon on the primary phosphines. Bisulphide of carbon acts upon both methyl and ethyl phosphine (Hofmann, B. 4, 433, 610), but the products have not been investigated. Michaelis a. Dittler (B. 12, 338) have studied the action of both reagents on phenyl phosphine. When carbonyl chloride is passed slowly into that substance, an energetic reaction occurs in the following manner:

2COCl₂ + C₆H₃PH₂ = C₆H₅PCl₂ + 2CO + 2HCl₂Phenyl phosphine and bisulphide of earbon act upon each other when heated in a scaled tube at 150°, and sulphuretted hydrogen is liberated. The product of the reaction is a resinous body (CaHaPHCS)2S, and the reaction itself proceeds according to the equation

 $2C_6H_5PH_2 + 2CS_2 = (C_6H_3PHCS)_3S + H_3S_2$ Michaelis a. Dittler were not successful in their attempts to prepare a phosphorised mustard oil Lom this compound.

They were equally unsuccessful in obtaining phosphorised carbylamine by the action of chloroform and caustic potash on phenyl phosphine. It is true that a reaction occurs, but its course is completely different from that which takes place with an amine, viz. :

 $C_8H_8PH_2 + 4KHO + CHCl_3 = C_8H_8PHKO_2 + 3KCl + CH_3OH + H_2O.$

It thus appears that, in their behaviour with carbonyl chloride and a mixture of caustic potash and chloroform, primary phosphines behave in an entirely different manner from the corresponding amines, though there is a certain degree of analogy as regards the action of both on bisulphide of carbon. This difference is no doubt due to the strong affinity of phosphorus for electronegative elements, such as the halogens, oxygen, and sulphur. Chloracetic and bromacetic acid react with benzyl phosphine. and chloroformic ether appears to form a product of addition (Letts a. Blake, l.c.). Probably other physphines act in a similar Methyl and ethyl manner with these reagents.

Primary phosphines readily combine with ! alkyl iodides to give hydriodides of secondary phosphines.

General properties of the secondary phosphines. The followings secondary phosphines have been obtained:

 Letts a. Blake, Le.

All the secondary phosphines obtained as yet are liquids, having a powerful odour. They are insoluble in water, but soluble in other &c.

 Hold, B. 6, 296.
 Michaelis, B. 15, 801 v. • Hofmann, B. 6, 300.

They have as a rule a strong attraction for oxygen, fuming and growing hot on exposure to the air, and often inflaming spontaneously. In some cases they appear to have even a greater affinity for oxygen than the primary bases. This is so according to Hofmann with all the secondary phosphines of the fatty series which he obtained. But apparently it is not the case with diphenyl phosphine. The products of this spontaneous oxidation do not appear to have been examined except in the case of dibenzyl phosphine, which yields dibenzyl phosphinic (phosphonic) acid and possibly the oxide also (C,H,)₂PO (Letts a. Blake, l.c.). But the products of their oxidation by nitric acid have been investigated, chiefly by Hofmann (B. 5, 104; 6, These are in all cases phosphinic acids, R₂PHO₂, which are monobasic, and no doubt have the constitution R.P(OH) O.

These acids are probably also produced when the chlorides R.PCl are oxidised by nitric acid. Such is at least the case with (CoH2)2PCL Some of them can be distilled unchanged, e.q. dimethyl phosphinic acid; others, e.g. diphenyl and dibenzyl phosphinic acid, lose water, and give pyroacids.

Secondary phosphines combine with acids, the resulting salts being far more stable than those of the primary bases. Thus in most cases they are not decomposed by water, though some are (e.g. salts of diphenyl phosphine). Comparatively little is known regarding secondary phosphines, and very few of their compounds have been investigated.

Sulphur acts upon them, and in the case of diethyl phosphine, according to A. W. v. Hofmann a. Mahla (B. 25, 2436), triethyl phosphine sulphide and diethyl dithiophosphinic acid. PEt2SSH are formed, together with a third substance which probably has the composition PSEt, S.S.PSEt, Bisulphide of carbon also acts upon them, but the products do not appear

to have been investigated. They readily combine with alkyl iodides, giving hydriodides of tertiary phosphines.

The tertiary phosphines hitherto obtained are, with the exception of triplienyl and tribenzyl phosphine, liquids at ordinary temperatures, having a powerful odour. They are insoluble in water, but soluble in ether &c. As a rule, they oxidise rapidly in contact with the air, fuming and growing hot, and in some cases igniting spontaneously. The product of this oxidation is a tertiary phosphine oxide of the formula R₃PO, and, no doubt, of the constitution R₂P:O. The final products of the oxidation of phosphuretted hydrogen, and of primary, secondary, and tertiary phosphines, are therefore respec-tively: H₃PO₄, RH₂PO₅, R₂HPO₅, R₃PO, the amount of oxygen absorbed by the phosphine decreasing in a regular manner as the series is ascended.

The oxides of tertiary phosphines are solid substances of remarkable stability. They can in the majority of cases be distilled, and even boiled with nitric acid, without change. By no means as yet discovered can they be reduced. Hydracids combine with them, and they give crystalline compounds with a number of metallic salts, such as the cl. orides of platinum, zinc, mercury, iron, cobalt, &c., also in some cases with chloride of acetyl, bromine, and sulphur.

Tertiary phosphines also combine with the elements of the sulphur group, forming compounds analogous to the oxides.

The salts of tertiary phosphines are readily obtained by dissolving the bases in acids. They are stable, and are not, as a rule, decomposed by water. Their compounds with hydracids have been chiefly studied; those containing oxyacids have not been investigated (with very few exceptions). The haloid salts dissociate to a greater or less extent on heating. Their hydrochlorides combine with chloride of platinum to give chloroplatinates of normal composition.

Some of the tertiary phosphines combine with chloracetic acid to give hydrochlorides of phosphorised betaines. At present only two or three of these substances have been obtained - trimethyl phosphorus betaine by Meyer (R. 4, 734), the corresponding ethyl derivative by Hofmann (Pr. 11, 530), and in addition to these two the closely allied compound, tri-methyl phosphorus benzo-betaine hydrochloride, by flichaelis a.

Ozimatis (B. 15, 2018), (CH₃)₃PCl.C₈H₄.COOH.

The compounds of these phosphorised betaines are stable and well-defined substances. Letts (Tr. E. 30, pt. 1, 285) has investigated the reactions and decompositions of the ethylated body,

which are of some interest.

The hydrate and the salts of this betaine lose carbonic anhydride when heated, and give rise to the hydrate or salt of methyl-tri-ethyl-phosphonium

 $(C_2H_b)_3PX.CH_2.COOH = CO_2 + (C_2H_5)_3PX.CH_3$ a reaction which is entirely analogous to that occurring when the corresponding sulphur compounds(thetines) are heated: (CH,) SX.CH, COOH = CO₂ + (CH₃)₂SX.CH₃. While it is perfectly different from that which the true (nitrogen) betaines experience, as they either dissociate into the original trialkyl-amine and the group X.CH, COOH (or the products of its decomposition), or distil unchanged (Brühl, A. 177, 214).

Treated with caustic potash, all the salts of tri-ethyl phosphorus betaine yield tri-ethyl phosphine oxide: $(C_2H_1)_3PX.CH_2.COOH + 2KHO$ = $(C_2H_2)_3PO + KX + CH_3.COOK + H_2O$. Several of the tertiary phosphines combine

directly and energetically with a molecule of bisulphide of carbon to give highly characteristic compounds, usually of a red colour, and possibly having the constitution, R₃P<S. So characteristic and so readily formed is this compound in the case of tri-ethyl phosphine, that its production may be employed as a test either for bisulphide of carbon or for the phosphine itself. As yet these (bisulphide) compounds have been obtained only with methyl, ethyl, and iso-propyl phosphine, and with those of the aromatic phosphines containing ethyl or methyl groups.

According to Czimatis (B. 15, 2016) these mixed phosphines combine very easily with bisulphide of carbon if they contain methyl, tho readiness with which combination occurs diminishing, however, in proportion to the molecular weight of the aromatic radicle, while, if they contain ethyl, combination occurs only slowly and with difficulty. Hofmann (Tr. 1860, 431 has somewhat exhaustively studied the compound of tri-ethyl phosphine and the bisulphide, which forms with explosive violence. Among its properties are the following: It is insoluble in water, difficultly soluble in ether, but easily dissolves in hot alcohol, from which it separates on cooling in red needles like chromic anhydride. From an ethereal solution it is deposited by spontaneous evaporation in large deep-red monoclinic crystals exhibiting dichroism, which melt

at 95° and volatilise at 100°. It is soluble in strong hydrochloric acid, and if the solution is mixed with platinic chloride, a yellow amorphous compound is produced, 2(C.H.), PCS, PtCl. When heated with silver oxide or nitrate, it is decomposed as follows: (C2H4)2PCS2+2Ag2O = Ag₂S + Ag₂ + CO₂ + (C₂H₅)₃PS, and moist air produces a similar change. But if is heated with water to 100°C., the following reaction occurs:-

 $\begin{aligned} &4(C_{a}H_{\bullet})_{a}PCS_{a}+2H_{\bullet}O\\ &=2(C_{a}H_{\bullet})_{a}PS+(C_{a}H_{\bullet})_{a}PO+(O_{a}H_{\bullet})_{\bullet}(CH_{\bullet})POH+3CS_{a}. \end{aligned}$

Heated with sulphuretted hydrogen, it suffers the following change: 3(C,H,),PCS2+H2S

 $= 2(C_2H_3)_3PS + (CH_2S)(C_2H_3)_3PCS_2 + CS_2$ The action of halogens upon tertiary phosphines has not been very fully studied. Probably direct addition would occur in all cases. This has been proved to take place with tri-ethyl phosphine if the halogen is allowed to act very gradually upon it. The chloride (C₂H₅)₄PCl₂ thus obtained is crystalline, melting at 100° and volatilising readily, though its boiling-point is high. Similar compounds of bromine and iodine have been obtained.

Compounds of tri-methyl and tri-ethyl phosphine with mustard oils are formed easily, and give crystalline hydrochlorides. They, no doubt, have the constitution, S:C:NR:PR_s.

[Note.—Some of the aromatic tertiary phosphines, especially tri-phenyl phosphine, have properties which differ materially from those of other tertiary phosphines. Thus tri-phenyl phosphine is a crystalline solid having scarcely any odour, and it does not oxidise spontaneously. It is remarkably stable, and is not attacked by chlorine even when heated. The hydriodide and hydrochloride are formed when it is dissolved in the warm concentrated hydracids, and are crystalline, but on adding water they dissociate. By treating the phosphine with bromine and an alkali, or by oxidising it with hydrochloric acid and chlorate of potash, the hydrate (C, H,), P(OH), is obtained as a crystalline solid. This when heated to 100° readily loses water, and is converted into the oxide, a substance which is not acted upon by bromine, oxygen; sulphur, &c. By dissolving the phosphine in fuming nitric acid a nitrate of the formula (CaHa) P(NO3)2 is obtained.]

Tertiary phosphines, apparently without exception, unite with alkyl iodides to form phosphonium salts.

General Properties of Quaternary Compounds (Phosphonium Salts). So many of these bodies have been obtained that a list appears inad-It would include derivatives of the visable. series C_nH_{m+1} to the 5th term, one or two of the series C₁H_{2n-7}, and a large number of mixed phosphoniums containing various radicles, among which are vinyl, allyl, and ethylene.

The phosphonium salts are the most stable of all organic phosphorus compounds. None are decomposed by water, and most of them can be obtained readily in the crystalline state by evaporating their solutions.

As a rule, they are soluble in water and in alcohol. They are readily prepared from their . iodides, either by double decomposition with a silver salt, or by first obtaining their hydrates (by the action of meist oxide of silver), and

subsequently neutralising the solution with the acid.

The hydrates R.POH are solid substances, having a powerful alkaline reaction and many properties similar to those of an alkali. Indeed. in the case of tetrethyl phosphonium hydrate, the only remarkable point of difference between it and caustic potash (so far as its reactions with metallic salts &c. are concerned) is that, when added to a zinc or aluminium salt, the zinc or aluminium hydrate, which is at first precipitated, is insoluble in an excess. Phosphonium hydrates are decomposed when heated, and in some cases, when their solutions are boiled or at the moment of production, into a tertiary phosphine oxide and a hydro-carbon,

$$R_3POH = R_3PO + R - H$$
.

The action of heat upon the salts of the phosphoniums has been investigated in a number of cases, partly by Letts and N. Collie (Tr. E. 30, part 1, 213; P. M. August 1886), and partly by the latter chemist alone.

As regards the haloid salts, the chlorides decompose almost quantitatively into a hydrocarbon and a tertiary phosphine hydrochloride (Collie), furnishing an excellent method for retrograding' from quaternary to tertiary

When the phosphonium chloride contains several ethyl groups, then if more than one of the latter is present, ethylene is always formed, e.g. $(C_2H_5)_3(C,H_7)PCl = (C_2H_5)_2(C,H_7)P.HCl + C_2H_1.$ But when only one ethyl group is present, then, although ethylene is still formed, two decompositions occur, e.g. (1)

 $2(C_2H_5)(CH_3)_3PCl = 2(C_2H_5)(CH_3)_2P.HCl + C_2H_4$ (2) $(C_2H_5)(CH_3)_3PCl = (CH_3)_3P.HCl + C_2H_4$. If we compare the decomposition by heat of phosphonium chlorides with the decomposition of any of the compound ammonium salts, it must be with the hydroxides and not with the corresponding chlorides' (Collie, C. J. 1888, 636, 711), e.g.

$$\begin{array}{lll} (C_2H_3)_2POI &= (C_2H_3)_3P.IICI + C_2H_4 \\ (C_2H_3)_4NOH &= (C_2H_3)_2N + C_2H_4 + II_2O \\ (C_2H_3)_4(C_3H_3)POOH) &= (C_2H_3)_2PO + C_3H_4 \\ (C_2H_3)_2(CH_3)NCI &= (C_2H_3)_3N + CH_2CI. \end{array}$$

The effect of heat on phosphonium salts derived from oxyacids is completely different. In the case of the ethyl series at all events, they suffer, as a rule, at least two, and occasionally three, different and distinct decompositions. In one of these the molecule splits up into three new groups, consisting respectively of carbonic anhydride, a (paraffin) hydrocarbon, and the tertiary phosphine. In the other, two hydrocarbons are formed-namely, an olefine and a paraffin-in addition to carbonic anhydride and the tertiary phosphine. Whilst in the third, a totally different change occurs, in which only two products are formed-namely, the oxide of the tertiary phosphine and a ketone,

(1)
$$\operatorname{Et_2P} < \frac{\operatorname{C_2H_3}}{\operatorname{OOC_1}\operatorname{R}} = \operatorname{Et_2P} + \operatorname{CO_2} + \operatorname{C_2H_3R.} \bullet$$

(2)
$$Et_{2}P < \frac{C_{2}H_{4}}{OOC}H_{2} = Et_{2}P + CO_{2} + C_{2}H_{4} + RH$$

It is possible, if not indeed probable, that the third reaction occurs subsequently to the first, and that it really depends upon the reducing action of the triethylphosphine upon the carbonic anhydride, at the high temperature at which the decomposition usually occurs, whereby carbonic oxide is liberated, which combines with the hydrocarbon radicle in statu nascendi, forming

$$\begin{aligned} & \text{Est}_3 \text{P} + \text{CO}_2 + (\text{Et}) + (\text{R}) = \text{Et}_3 \text{PO} + \text{EtCOR} \\ & \text{(or Et}_3 \text{P} + (\text{OCO} - \text{R}) + (\text{Et}) = \text{Et}_3 \text{PO} + \text{EtCOR}). \end{aligned}$$

If we merely consider the third kind of decomposition alone, it appears to be, to a certain extent, analogous to the decomposition which a sulphine compound suffers when heated, the difference depending on the greater attraction which phosphorus has for oxygen, compared with that of sulphur for the same element. In both cases a hydrocarbon group is detached from the molecule, and also the residue of the acid, but while with the sulphur compounds these two simply combine (forming a compound ether), and leave a hydrocarbon sulphide, in the case of the phosphonium salt the acid residue is reduced by the tertiary phosphine, and the group thus left combines with the hydrocarbon radicle, forming a ketone.

$$Et_{2}S < \frac{Et}{OOCR} = Et_{2}S + EtOOCR.$$

$$Et_{3}P < \frac{Et}{OOCR} - Et_{3}PO + EtOCR.$$

A result of this kind is in perfect harmony with the views expressed by Crum Brown and Letts (Tr. E. 28, 371; Letts, Tr. E. 30, 285) regarding the analogies and differences existing between phosphorus and sulphur and their compounds.

When the phosphonium salts contain ethylene they suffer a different decomposition under the influence of heat; at least this has been ascertained to be the case with the bromide of bromo-ethylene-triethylphosphonium, and the bromide of hydroxy-ethylene-triethyl phosphonium, which decompose as follows (Hofinann) :-

 $C_aH_aBr.P(C_aH_a)_aBr = HBr + (C_aH_a)(C_aH_b)_aPBr$ $C_2H_1(OH).P(C_2H_2)_3Br = H_2O + (C_2H_3)(C_2H_3)_3PBr$ and also in that of the hydrate of ethylene-hexethyl diphosphonium, which decomposes according to the equation: $C_2H_1(P(C_2H_3)_3OH)$ $= C_2H_1 + (C_2H_3)_3P + (C_2H_3)_3PO + H_2O.$ Masson and Kirkland (C. J. 1889, 126) have

studied the action of bromine and chlorine on the salts of tetrethyl phosphonium, the results showing a very close similarity between the polyhaloid derivatives of tetrethyl phosphonium and those of trimethyl sulphine and of tetramethyl ammonium previously described by Dobbin and Masson (C. J. 1885, 56; 1886, 846). The tendency to form solid poly-haloid compounds is, however, more marked. For the able, containing a list of the new substances, the methods of forming them, and their chief properties, the original memoir should be consulted.

Organic Phosphorus Compounds which cannot be placed in any of the above Groups. A phorphorised cacodyl (CH₁),P₂ (the methyl analogue of liquid phosphoretted hydrogen) was obtained by Thénard (C. R. 21, 144, 25, 829) by the action of chloride of methyl on phosphide of calcium, and is interesting not alone as being the sole representative (as yet prepared) of its class, but also as having been probably the first phosphine obtained. Thénard describes it as a colourless, highly refractive liquid, of an odour recalling that of cacodyl itself, insoluble in water, and boiling at about 250°. It inflames spontaneously in contact with air, but if exidised slowly gives a crystalline acid (CH₁), P₂H₂O₄= (CH₃)₂PHO₂ (dimethyl phosphinic acid?), analogous to cacodylic acid. Treated with an excess of hydrochloric acid, it is converted into trimethyl phosphine, and a solid yellow substance (CH₂), P₂ (which is also formed in the original reaction), and which Thénard regarded as the methyl analogue of solid phosphide of hydrogen.

Michaelis (B. 10, 807) obtained a substance, which he named diphosphenyl or phosphospersene, ch., P.P.C.H., (corresponding to axobenzene), by the action of phortyl phosphorous chloride on monophenyl phosphine C.H., PCl. + C.H., PH. = (C.H.), P. + 2 + 2 + C.H. It is a pale-yellow powder, insoluble in water, alcohol, and ether, but readily soluble in hot benzene, and is slowly oxidised by the air to (C. H.), P.Q. Treated with chlorine, phenyl phosphorous chloride is regenerated. With nitric acid it is oxidised to phenyl phosphinious (benzene phosphinic) acid C.H., PH.O. if the acid is dilute, but to phenyl phosphinic fonzene phosphonic) acid C.H., PH.O. if the acid is strong. Treated with hydrochloric acid, it reacts so as to regenerate the substances from which it is formed.

Michaelis (B. 7, 499) also obtained a substance, which he called di-phospho-benzene hydrate C.H. P.P.OH, by the action of spontaneously inflammable phosphoretted hydrogen on phenyl phosphorous chloride. It is a yellow powder, soluble with ease in bisulphide of carbon, taking fire on exposure to air, and oxidised by nitric acid to phenyl phosphinic (benzene phosphonic) and phosphoric acids. In addition to the above, Michaelis (B. 11, 885) obtained a phenylated solid phosphide of hydrogen (C,H,)HP, by treating phenyl phosphorous chloride with a quantity of water insufficient for complete decomposition (for instance, by keeping it in a badlystoppered bottle). It is a dark-yellow amorphous body, having a faint odour of phenyl phosphine, soluble in hot bisulphide of carbon, but insoluble in water, alcohol, and ether. Treated with chlorine it reacts as follows: (C₄H₅)HP₄+6Cl₂= 8PCl₂ + (C₅H₂)PCl₂ + HCl. Nitric acid oxidises it to a mixture of phenyl phosphinic (benzene phosphonic) and phosphoric acids.

The action of phosphonium iodide on aldehydes has been studied by Girard (A. Ch. [7] 2, 50), while that of phosphoretted hydrogen and hydrochloric acid on the same bodies and on ketonic acids has been investigated by Messinger and Engels (B. 21, 328, 2019). Girard obtained products of addition containing four molecules of the aldehyde (valerte, propionic, salicylic, and benzoic) to one of phosphonium iodide.

Messinger and Engels obtained similar bodies

Messinger and Engels obtained similar bodies by acting on the aldehydes with hydrochloric acid and phosphoretted hydrogen. The compounds thus formed are for the greater part solid, crystalline, and fairly stable. By treatment with water they are decomposed, and the aqueous solution gives the reactions of hydrochloric acid and phosphoretted hydrogen. Their constitution is probably represented by the formula (B.CHOH), PCI. Chloride of tetra-hydroxyethylidene phosphine (C,H,O), PCI is decomposed by caustic potash into the free phosphine (C,H,O), PC,H,O and the hydrate (C,H,O), P(OH). Benzaldehyde and its mono-nitro-derivative give compounds which differ from those obtained in the fatty series in that they contain no hydracid.

Messinger and Engels have summarised the results of their researches as follows: (1) Phosphoretted hydrogen does not act on an aldehyde alone, but is absorbed if at the same time a hydracid is present. The absorption occurs more completely if the aldehyde is largely diluted with ether. (2) The aldehydes of the fatty series combine with a molecula of phosphoretted hydrogen and a molecule of hydracid, while those of the aromatic series combine with phosphoretted hydrogen only, though in order that the compound shall be formed the presence of the hydracid is necessary. (With benzoic aldehyde the compound has the formula $(C_0H_1COH)_1PH_2$.) (3) The phosphorised derivatives of the fatty series have an unpleasant smell, and are decomposed by water, while those of the aromatic series have no odour, and are nearly insoluble in water. All are soluble with difficulty in ether, and in some cases are insoluble.

By the substitution of a ketonic acid for an addehyde in the above reaction, compounds are produced in certain cases. Thus levulic acid gives an oil, and pyruvic acid a solid compound,

either
$$(CH_3\cdot CO.CO)_3P$$
 or $(CH_3-C-C=0)_3P$,

which is a well-defined crystalline body, having neither busic nor acid praperties, soluble in alkalis with decomposition, and also decomposed when heated with acids. It dissolves, however, without change in glacial acetic acid, and crystallises cout on cooling. Boiled with water, it is decomposed into the substances from which it was originally produced. It forms crystalline compounds with aniline, phenyl hydrazine, and toluene diamine. E. A. L.

PHOSPHINIC ACIDS. The name oxy-ethylphosphinic acid has been given to the acid CHMe(OH).PO(OH),, which is got from aldehyde by successive treatment with PCl, and water. A more appropriate name for this acid is, however, oxy-ethane-phosphonic acid, the term phosphinic acid being reserved for acids R'P(OH)₂ containing trivalent phosphorus.

PHOSPHINO-BENZENE C.H., PO. Phosphenylic anhydride. [100°]. Formed from phosphenylic acid and POCI, (Michaelis a. Rothe, B. 25, 1747). White crystalline powder, v. sol. water, being reconverted into phosphenylic acid.

PHOSPHINO. \$\psi\$-CUMENE C_6H_Me_PO_[216]. Formed from C_6H_Me_PO(OH), and C_H_Me_POCl_4 (Michaelis a. Rothe, B. 25, 1749). Plates (from benzene), v. e. sol. chlosform. Converted by hot water into \$\psi\$-cumene phosphonic acid.

PHOSPHINO-TOLUENE C. H. Me. PO.: Tolus phosphonic anhydride. [101°]. Formed one phosphonic anhydride. [101°]. Formed from C.H., PO(OH), and C.H., POCl, (Michaelis a. Rothe, B. 25, 1748). Converted by water into toluene phosphonic acid.

PHOSPHITES. Salts of the acid H.PO.; v.

PHOSPHORUS, OXYACIDS OF, p. 151.

PHOSPHO -. Use of this prefix applied to inorganic compounds; for phospho-acids, phosphosalts, &c., v. the acids, salts, &c., to which phospho- is prefixed. Thus, phosphomolybdic acid and phosphomolybdates are described under MOLYBDENUM, ACIDS OF, AND THEIR SALTS.
PHOSPHO-AMIDO-BENZENE SULPHONIC

ACID PO, H, NH.C, H, SO, H. The chloride C, H, NSPO, Cl, [158] is formed from p-amidobenzene sulphonic acid and PCl, (Laar, J. pr. [2] 20, 250). It is converted by McOII and alcohol into Me₃A''' [114°] and Et₂A''' [102°] re-

spectively.

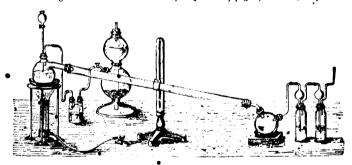

PHOSPHOBENZENE CaHaP:PCaHa. [150°].
Formed by slowly adding CaHaPRa to CaHaPCl. in a current of H (Köhler a. Michaelis, B. 10, 812). Yellowish powder, insol. water, alcohol, and ether, sol. benzene. On exposure to air it is oxidised to $(C_aH_3P)_2O$. Dilute HNO3 oxidises to phosphenylic acid. Chlorine, diluted with CO₂, forms C₆H₂PCl₂. Conc. HClAq forms phenyl-phosphine and C₆H₂PO₂H₂.

PHOSPHONIUM COMPOUNDS. PH, combines with the halogen acids HX to form com-

20 atmos. pressure at 14°, or by cooling to -25° under ordinary pressure (Ogier, C.~R.~89,.705). Skinner (Pr. 1887, 283) found the critical temp. to be 48° under 95 atmos.; and the maximum vapour-pressure line to be below those of HCl and PH, at all temperatures; from - 80° to 10° the line was normal, above 10° combination began; at temperatures near the critical the volume of liquid PH,Cl formed was nearly half that of the liquid constituents.

PH₄ is strongly compressed in presence of water the PH, liquelies and floats on the water. If the pressure is now suddenly decreased, white crystals are formed; these crystals are probably PHOH (no analyses have been made). The production and dissociation of the crystals occur at definite pressures and temperatures. No formation occurs above 28° at any pressure. The crystals can be distilled from one part of the tube to another by gently warming (Callletet a. Bordet, C. R. 95, 58). When equal volumes PH, and CO, are compressed in presence of water, below 22°, the gases disappear and white crystals are formed, which C. a. B. (l.c.) take to be a mixture of PH.OH and the hydrate CO...8H.O

discovered by Wroblewski (С. R. 94, 954). Рноврномим попик РН.І. Н.Г. [Р.Н.І.] = 29,500 (solid PH,I from H, solid P, and solid I); [PH3,HI]=24,100 (solid PII,I from gaseous PH, and HI) (Ogier, C. R. 89, 705). This com-

pounds PH,HX. The reactions of these compounds are most simply expressed by regarding them as salts of the radicle PH; following the analogy of the ammonium compounds, the bodies PH,X are called phosphonium compounds. The mol. weights of these compounds have not been determined.

PHOSPHONIE M BROMIDE PH.Br. $[PH^3,HBr] = 23,000$; $[P,H^4,Br] = 44,100$ (solid PH Br from H, solid P, and liquid Br) (Ogier, C. R. 89, 705). Colourless cubes; melts at 30. V.D. 27.7 corresponding with that required by PH, + HBr (Bineau, A. Ch. [2] 68, 431). Deliquesces in air; decomposed violently by water to PH, and HBrAq. Prepared by bringing together PH, and HBr (Serullas, S. 64, 233); by leading PH, into cold conc. HBrAq (Ogier, C. R. 89, 705); by heating conc. HBrAq with P to 100°-120° (Damoiseau, C. R. 91, 883).

PROSPHONIUM CHLORIDE PH.Cl. Formed in solourless crystals, melting at c. 25°, by subjecting a mixture of equal volumes HCl and PH, to eapacity, and to this solution, kept cool, 680 g.

pound was discovered by Labillardière and Gay-Lussac (A. Ch. [2] 6, 304), and more fully examined by Serullas (S. 64, 238) and H. Rose (P. 24, 151; 46, 636).

Formation .- 1. By bringing together PH. and HI as gases or in conc. aqueous solutions .-2. By the action of gaseous PH, on I (Hofmann, A. 103, 355).—3. By the action of red Pon conc. HIAq at 160° (Oppenheim, Bl. [2] 1, 163).—4. Along with P2I, by the action of HI gas on P at ordinary temperatures (Damoiseau, C. R. 91, 883). - 5. By the action of a little water on PI, (v. Preparation).- 6. By the reaction of HI on 11, PO, and warming the product in CO, (Lissenko, B. 9, 1313).

Preparation.—P and I are combined in CS. solution, and the product is decomposed by a little water (Baeyer, A. 155, 269; Hofmann, B. 6, 286). Hofmann (l.c.) gives the following directions: 400 g. P are dissolved in the same weight of dry CS, in a retort of 1 litre I are added by small portions. The whole of the QS, is then distilled off on a water-bath, an operation which takes 9 or 10 hours. The retort is then connected with a long wide condensing tube, and a two-necked globular receiver, from which a connecting tube passes to two condensing bottles, the first containing dilute HIAq, the second water (see fig.). Heat is then applied to the retort, gently at first, and 240 g. water are slowly added through the drop-funnel. . PH,I and HI are formed; the HI collects in the con-densing bottles, and the PH, I forms a crust, chiefly in the tube, and in smaller quantity in the globular receiver, which, to prevent stoppage, should be connected with the long tube by a wide tube. To prevent the liquid in the condensing-bottles from being forced back in consequence of the rapid absorption, a slow stream of CO, is passed through the apparatus during the whole operation. A well-conducted sublimation may be completed in 8 or 9 hours. When it is finished one end of the long condensing tube is closed with a cork, and the PH.I is detached by means of a stout wire bent and sharpened at the end. Hofmann expresses the reaction thus: $18P + 9I + 21H_{0}O = 7PH_{1}I + 3H_{4}P_{2}O_{7} + 2HI$. The PH,I may be sublimed in dry HI.

-Properties. - Large, clear, lustrous, pyramidal crystals; boils at c. 80°; may be sublimed in HI.

Reactions.—1. With carbon compounds reacts as a very energetic reducing agent, and is much used in preparing phosphines &c. (v. Phosphines).—2. Decomposed rapidly by water or alkali solution, evolving non-inflammable PH, (v. Phosphorus tranvorder, Preparation 2, p. 136).

S. With alcohol forms Etl and PH,; if the reaction is conducted in a scaled tube PEt, and PEt, I are produced.—4. With phosphorus trichloride forms P,I, HCl, PH,, and solid P,H (de Wilde, B. 16, 217).—5. PH,I is inflamed by contact with many cone acids, e.g. 11NO₃, HCl, HBr, HI.

Phosphonium sulphate. When PH₃ is passed into H₂SO₂ at ordinary temperatures much heat is produced, S separates, and SO₂ is formed. The reaction is much slower if the acid is cooled by ice and salt; if the H₂SO₃ is cooled to -20° or -25° (by rapid evaporation of CH₃Cl) a syrupy liquid is formed, from which a white, crystalline, very deliquescent solid separates; this solid seems to be phosphonium sulphate [?(PL₃),SO₃] (Bosson, C. R. 109, 644). Exposed to air, H₃PO₃, and H₃PO₂ are formed with SO₂, S, and a little H₂S; dissolves in water with hissing noise and evolution of PH₃, but no reduction of the H₂SO₄. M. M. P. M.

PHOSPHORIC ACIDS. In this article are described the three acids, H₁PO₄, HPO₃, and H₄P₃O₇; the salts of these acids are described under Phosphates (p. 106); for the other oxyacids of P and their salts v. Phosphorus, OXYACIDS OF, AND THEIR SALTS (p. 149). The oxide P₂O₅ is the anhydride of three acids: cold water added to P₂O₅ forms HPO₃, the long-continued action of moist air on HPO₅ produces H₄P₄O₇, and H₂PO₄ is formed by boiling for some time an aqueous solution of HPO₅ or H₄P₂O₇. The three acids may be formulated as P₂O₅. H₄O, P₂O₅. 2H₄O, and P₂O₅. 3H₄O (cf. Phosphates, p. 106).

Obthophosphoric acid. Phosphoria acid. Tribasic phosphoric acid.) S.G. 1-88 (Schiff, A. 113, 183). Melts at 41.75°; liquid solidifies at 38°, temperature rising to 40.5° (Berthelot, Bl. [2] 29, 8). H.F. [P,O',H'] = 302,600 (formation of solid acid); 300,080 (formation of molten acid); [P,O',H',Aq] = 305,230 (Th. 2, 225). Heat of fusion = -2520 (Th., l.c.). One mol. w. of the molten acid in grams occupies 52.02 c.c. (Th., l.c.). \(\mu_1\): 3584, \(\mu_1\): 3585, \(\mu_1\): 365, \(\mu_1\): 3746, for H,PO,Aq. S.G. 1·11 (=29 p.c.) (Gladstone, C. J. [2] 8, 101, 147). Affinity in aqueous solution = c. 25 (HNO₂ = 100) (Ostwald).

Formation.—1. By oxidising P, by long exponents

sure to moist air (Leeds, A. 200, 286; Wenzell, Ph. [3] 14, 24), or by HNO, HClO, HClO, SO, NO2, &c.; phosphates are formed by treating P with many metallic oxides, and with alkali carbonates.—2. By oxidising H.PO,Aq or H.,PO,Aq by ClAq, BrAq, or IAq, HClOAq, HNO,, or by Ag.O or HgO; H.,PO,Aq is oxidised to H.,PO,Aq by standing in air.—3. By reaction of boiling water with P₂O₃, HPO₃, or H₄P₂O₅,—4. By burning PH, in moist air or O .- 5. By reaction of water with POCl3, or much water with PCl3.-6. By oxidising, by HNO,Aq, the mixture of H,PO,Aq and H,PO,Aq obtained in making HI by the action of P, I, and H,O (Pettenkofer, A. 138, 57).—7. By decomposing many phosphates, e.g. $Ca_3P_2O_8$, by H_2SO_4 ; $Pb_3P_2O_8$ decomposed by H.S in presence of water gives H.PO.Aq. For production from bones v. DICTIONARY OF APPLIED CHEMISTRY .- 8. By decomposing (NH,)H,2PO, by warm cone. HClAq, separating NH,Cl after cooling, and evaporating with HNO, till all NH, salts and HCl are expelled (Joly, C. R. 102, 316).

Preparation .- One part P is mixed with 10-12 parts HNO, Aq (free from H2SO,) S.G. 1.2 (the acid must not be more cone than this) (Kranthausen, Ar. Ph. [3] 10, 410) in a large retort, the beak of which passes loosely into a receiver placed in cold water; about 3 to 6 gently warmed until the P has completely dissolved. Should any liquid distil over, it is returned to the retort. Oxidation proceeds more regularly, and at a lower temperature, when a little I is present than when HNO, Aq alone is used (Horn, Ph. [3] 10, 468; Ziegler, D. P. J. 258, 239). If I is not added, and the acid is more cone, than S.G. 1.2, violent explosions may occur. Von Schrötter recommends the employment of amorphous P and acid more conc. than When the P is all dissolved, the con-S.G. 1.2. tents of the retort are boiled, and 5-7 parts of the liquid are distilled off (the distillate is HNO, Aq, S.G. 1.1 to 1.14). During this part of the process copious evolution of NO2 often occurs, due to the oxidising action of INO, on H.PO,. According to Reinsch (J. pr. 28, 385) little NO, but much N, is formed during the oxidation of P by HNO, at boiling temperature in absence of air, but much NO is produced in an open vessel at low temperatures. The liquid in the retort is evaporated in a basin until the fumes cease to turn blue litmus red. During this operation NO. is often freely given off (especially if little or none of this gas has been produced in the retort), as the oxidation of H_sPO_s is not alwaysecom-pleted until the liquid has been evaporated; ahould no gas be evolved it is advisable to add a little cone. HNO₂Aq to the liquid in the basin after concentration, and again evaporate till acid fumes cease to come off. The liquid in the basin is diluted with water, saturated with H₂S, kept in a warm place for 24 hours, and filtered from As S₃ (and Sb₂S₃); which may separate (ordinary P generally contains As). The filtrate is then evaporated, at a temperature not above 150°, until it becomes a thick syrup on cooling, and the cold liquid is placed over H₂SO₄, when it slowly solidities. By evaporating the syrup in vacuo over H₂SO₄, crystalline tablets of H₂PO₄ are obtained; a fragment of these placed in acid S.G. 1.8 (or more cone.) immediately causes crystallisation (Huskisson, B. 17, 161).

Properties.—A thick semi-solid mass, S.G. 1788 (Schiff, A. 113, 183); also obtained in crystalline tablets by evaporation of the syrup S.G. 1788 in vacuo over H.SO., According to Berthelot (Bl. [2] 29, 3) crystals of H.PO., melt at 47.75°; the liquid solidifice at 38°, with a rise of temperature to 40.5°. H.PO., is tribasic, forming salts M'H.PO., M'.1HPO., and M'.1PO. in aqueous solution is about 25 (HNO. = 100) (Ostwald). Both crystalline and syrup-like H.PO. deliquesee in air. The acid dissolves readily in water; Hager (in his commentary to the Pharmacopacia Germanica) gives the adjoining table.

According to Sieber (Ph. [3] 9,598), H,PO,Aq containing 5 p.c. acid (or even less) stops putrefaction.

Reactions. - 1. Heated to c. 213°, H.P.O, is formed; at a higher temperature HPO, begins to be formed, and at full red heat only HPO, is produced .- 2. Is not decomposed by electric current, according to Luckow (Fr. 1880.1); by electrolysis of H₁PO₁Aq, using C poles, Bartoli a. Papasogli (G. 11, 239, 468; 12, 113, 117, 125) obtained a substance containing C and P, which they called phosphomellogen. Molten H.PO., on electrolysis, gives off H and O, and forms H,P,O,, then HPO₃, and then II₃PO₃, and inflammable P hydride (Janecek, C₂ C. 1888, 273).—3. It is not certain whether water forms hydrates with HaPO, when the acid is dissolved in water (v. Crompton, C. J. 53, 116). -4. By adding alkali solutions to H₃PO,Aq till neutral, salts M₂HPO, are formed; addition of considerable excess of alkali produces M3PO4. For connection between quantity of alkali added and electrical conductivity of the solution, v. D. Berthelot (C. R. 113, 851) .- 5. Reacts with phosphorus pentachloride at ordinary temperatures to form POCl, and HCl; with phosphorus oxychloride when hot to form HPO3 and HCl, or H,P2O, and HCl, according to the relative quantities of H,PO, and POCI,; with phosphorus trichloride to form HPO, H,PO, and HCl; and with metaphosphoric acid to form H,P,O, (Geuther, J. pr. [2] 8, 359). For reactions of salts of H,PO, v. Phosphates, p. 107. For nitriles of H.PO, v. PHOSPHAM (p. 104), and PHOSPHORUS OXYNITRIDE (p. 144); for amide and imido amide .v. Phosphamides (p. 105) and PHOSPHAMIDO-IMIDE (p. 105). For thio-amide v. PHOSPHORUS SULPHOCHLORIDE, Reaction(p. 148).

PYROPHOSPHORIC ACID, H₄P₂O₇.

Preparation.—1. An impure acid, containing some E.PO, and HPO,, is obtained by heating H,PO, to 218° until a little dissolved in cold

water gives a white pp., without a trace of yellow Ag, PO,, with AgNO, Aq, after neutralisation by NH, Aq. -2. Péligot (A. Ch. [2] 73, 286 obtained crystals of H.P.O, by allowing glacial HPO, to stand in moist air in a bottle for some years. Crystals of H₃PO₄ formed at the top of the bottle, a liquid S.G. 1.7 in the middle, and the bottle, a liquid S.G. 1.7 in the middle, and erystals of H₁P₂O₂ at the bottom.—3. An aqueous solution of H₂P₂O. is obtained by decomposing Pb₂P₂O₂ suspended in water by H₂S, filtering from PbS, and allowing the H₂S to evapocate at the ordinary temperature (Geuther, J. Jr. [2] & 559).—4. By heating together H₁PO₄ and HPO₃ in the ratio HPO₃:H₂PO₄.—5. By the reaction of H₂PO₄ and POCl₃ in the ratio 5H₃PO₄:POCl₃ (G., Le.).

Properties and Reactions—A classification

Properties and Reactions. - A glass-like solid; Péligot (A. Ch. [2] 73, 286) obtained the acid in non-transparent crystals resembling loaf-sugar. Dissolves readily in water; dilute solutions remain unchanged at ordinary temperatures (Graham), when heated H,PO,Aq is formed. The solution, neutralised by NH,Aq, gives a white pp. of Ag.P.O. with AgNO.Aq. H.P.O. is tetrabasic; for description of salts c. Phosphates, p. 107. When heated with 70. PROSPIATES, p. 107. When heated with the problem of the proble HPO, and HCl (G., l.c.). For the amic acids of H,P,O,, and other amic acids derived from hypothetical condensed pyrophosphoric acids, v. Рнозримис астов (р. 105).

Метарновий асто HPO3 (Graham, T. **1833. 253).**

Preparation.-1. H.PO.Aq or II.P.O.Aq is evaporated to dryness and the residue heated to full redness until H₂O ceases to be evolved. - 2. PbP₂O₄ is suspended in water and decomposed by H₂S, the filtrate from PbS is evaporated to dryness and heated to full red heat .- 3. By the ting together H₂PO₄ and POCl₂ in the ratio 2H₂PO₄:POCl₃, or H₁P₂O₇ and POCl₂ in the ratio 2H₂P₂O₇:POCl₃, or H₄P₂O₇ and PCl₃ in the ratio 3H, P,O,: PCl, (Geuther, J. pr. [2] 8, 359).—4. By reacting on H.PO.Aq with Cl or Br .- 5. A solution of P2O, in a little cold water contains HPO.

Properties and Reactions.—According to Tammann (J. pr. [2] 45, 417), two varieties of HPO, exist; one is a soft, silky mass, formed by heating HaPO, until one molecule of H.O is removed; the other is obtained by heating H,PO, until it sets to a glassy mass on cooling. A transparent, colourless, glass-like solid. Ordinary glucial phosphoric acid is impure HPO,, generally containing considerable quantities of Na salts, and some H₂PO₄ or H₁P₂O₇. Very hygroscopic, soon deliquesces in air. Volatilised completely at bright-red heat (H. Rose, A. 76, 2, 13; 77, 319). Not dehydrated by heat nor by the action of dehydrating agents. Heated with PCl, forms POCl, and HCl, HPO, Aq is changed to H, PO, Aq. forms slowly at ordinary temperatures, more rapidly by boiling or by adding HClAq or HNO,Aq. (For rate of change v. Sabatier, C. R. 106, 63; 108, 738, 804.) HPO, is monobasic; several series of metaphosphates, some polymeric and some isomeric, exist (v. Phosphates, p. 106).

(Hittorf, P. 126, 193).

Historical .- In the early part of the seventeenth century a substance was prepared by heating heavy spar with combustible organic matter. e.g. egg-white and charcoal, and this substance glowed in the dark (Kopp, Geschichte der Chemie, iv. 42). From this time the name phosphorus was given to any substance which emitted light in the dark without being ignited $(\phi \omega \sigma \phi)^{\rho} \rho \sigma$ = light-bearer). The substance now known as phosphorus was prepared for the first time about 1670: Brand seems to have been the discoverer, but the discovery is sometimes attri-buted to Kunkel or to Boyle (for details v. Kopp's Geschichte der Chemie, iii. 327).

For a long time P was prepared in very small quantities; it was obtained by evaporating urine, mixing the residue with sand, and heating in a very hot fire. In 1737 charcoal was mixed with the sand and urine-residue. The discovery of phosphates in bones by Scheele in 1771, and in minerals by Gahn in 1780, led to the preparation of P on a comparatively large scale. The discovery of P played an important part in the development of the phlogistic theory. Phosphorus was supposed to be a compound of phlogiston with the acid which was formed when P was burnt; this acid was composed of phlogiston and muriatic acid according to Stahl. and of vitriol and muriatic acid according to Hofmann. Marggraf in 1743 determined that P increased in weight when burnt, and that P was obtained by heating phosphoric acid with combustible matter. In 1777 and 1780 Lavoisier showed that P was a constituent of phosphoric acid (cf. Kopp, l.c.).

Occurrence.-P is not found uncombined. Phosphates of Al and Ca occur in large quantities in many rocks; phosphates of Fe, Pb, Mg, and NH, &c. are also widely distributed minerals. Coprolites (the fossilised excrements of former land-animals) and guano (the excrement of certain birds) consist very largely of Ca phosphate. Phosphates also occur in some kinds of coal (Carnot, C. R. 99, 154). Phosphates of Ca and Mg are found in the ashes of plants and the bones of animals; P occurs in combination with C, H, and N in the yolk of eggs, in blood, in semen, and in nerve and brain matter.

Formation.—Ordinary phosphorus is formed: 1.—By heating CaPO, with powdered

charcoal, $3\text{Ca}(\text{PO}_3)_2 + 10\text{C} = 4\text{P} + 10\text{CO} + \text{Ca}_3(\text{PO}_4)_2$; or wicharcoal, $2\text{Ca}(\text{PO}_4)_2 + 10\text{C} + 2\text{SiO}_2$ or with SiO2 and

= $4P + 10CO + 2CaSiO_3$.—2. By reducing $Pb_3(PO_4)_2$ with charcoal (Donovan, P. M. [4] 2, 202; Foureroy a. Vauquelin, Gmelin's Handb. [6th edit.] i. 2, 95).—3. By decomposing a strongly-heated mixture of Ca₃(PO₃)₂ and C by HCl (Cari-Montrand, C. R. 38, 864).

Red phosphorus is formed: 1. By the action of light, heat, or electricity on ordinary P, whether the P be solid or in solution, dry or P, whether the P be sold or in solution, any or moist, at ordinary temperature or at -14° (Schrötter, W. A. B. 1, 130; C, 241; 9, 414; Corenwinder, A. Ch. [3] 30, 242; Lallemand, C. R. 70, 182; Hittorf, P. 126, 193; V. Meyer, P. 15, 267; Clear C. 7, 16, 260, 2, 38; Perset B. 15, 297; Grove, C. J. 16, 269).—2. By heating common P with a little I. One part of I suffices to transform c. 100 parts of P into the red variety, by melting the P, mixing in the I, and heating again; the mass becomes red at 100°, at 120°-130° a red powder separates, at 200° a more or less explosive action occurs and the change is complete (Brodie, J. pr. 58, 171).-3. By adding a little I to a solution of common P in CS, evaporating to dryness, adding water, and washing with CS, (Corenwinder, A. Ch. [3] 80, 242; Lallemand, C. R. 70, 182; Brodie, J. pr. 58, 171). Rüdorff (P. 128, 463) supposed the red substance thus formed to be a hydride of P.

1. Crystalline ordinary phosphorus is formed: 1. By heating red Pina vacuous scaled tube to 447° (Hittorf, P. 126, 193).—2. By dissolving ordinary P in molten lead and crystal-

lising therefrom (H., l.c.).

Preparation.—1. The details of the preparation of ordinary phosphorus from boneash are described in DICTIONARY OF APPLIED CHEMISTRY, vol. iii. Ordinary P frequently contains notable quantities of As, derived from the H2SO, used; this can be removed only by repeated treatment with dilute IINO, Aq. S.G. 1.1, a process which involves the loss of about 5 of the P (Herz a. Bärwald, B. B. 32, 2, 133; cf. Dulk, ibid. 34, 1, 247; also Wackenroder, J. pr. 2, 340; and Liebig, A. 11, 260). Traces of red P may be removed by shaking in a closed vessel with cone. K Cr.O.Aq and H.SO. (Wöhler, A. 45, 249). Lockver (C. N. 40, 101) found that a specimen of dry P gave off considerable quanti-ties of H when heated in vacuo.

2. Red or amorphous phosphorus.-A small flask of hard glass is fitted with a good cork carrying a short tube and an exit-time which dips just beneath the surface of a little Hg; the entrance tube is fitted with a stopcock. Dry CO. is passed through the apparatus for some time; a dry stick of common P is then placed in the flask, and the stream of CO₂ is continued for a little, after which the stopcock is closed, and the flask is heated on a sand-tray or in an oil-bath, to 240°-280°, for 50-60 hours. After cooling, a layer of red P is found at the bottons of the flask, generally covered by a mixture of the two kinds of P. The ordinary P is melted by running in a little water at 50°-60°; the water and melted P are poured off; the resi dual red P is washed repeatedly with CS₂ (addition of CaCl₂Aq, 38°-39° Beaume, causes the CS2 solution to rise to the surface; Nickles, C. R. 42, 646), or with boiling KOHAq S.G. 1.3, and then with water containing a little HNO,; the red P is finally washed with water. and dried at c. 100° (Schrötter, W. A. B. 1, 130; 8, 241; 9, 414).

The change of common into red P occurs in ten minutes by heating the former to 300° in scaled tubes of thick glass, from which the air has been pumped out (Hittori, P. 126, 193; V. Meyer, B. 15, 297).

3. Crystalline metallic phosphorus. Hittorf (P. 126, 193) claimed to have formed a distinct variety of P by heating red P in sealed tubes of hard glass to c. 417° (in vapour of S): and also by dissolving common P in molten lead and crystallising. A wide tube of hard glass is closed at one end, filled to 4 with common P and then filled with pieces of lead; the open end is narrowed, and the air is pumped out of the tube, which is then sealed. The tube is embedded in calcined MgO, placed in an iron tube, and heated above the melting-point of Pb for 8-10 hours. After cooling, the Pb is dissolved in HNO, Aq, S.G. 1.1, and violet-black crystals of P remain; these crystals have not, however, been obtained quite free from lead.

Properties. - P exists in three, and perhaps in more than three, modifications.

1. Ordinary, octahedral, or stick phosphorus is a semi-transparent, colourless. or stick crystalline solid, with a very distinct smell. The smell is very probably due to a mixture of ozone and P2O3, formed by the oxidation of the P (Schönbein, P. 65, 377; Thorpe a. Tutton, C. J. 57, 573). When melted and cooled quickly P is opaque; when cooled slowly it is nearly as clear as water. P must be kept under water; if the water is free from air the P remains transparent (Baudrimont, C. R. 61, 857). In ordinary water

P becomes covered with a whitish film, but this again becomes transparent at-c. 50° (H. Rose, P. 27, 563; Baudrimont, l.c.). According to Marchand (J. pr. 20, 506) the white film contains from 4 to 7 p.c. water; Pelouze (A. Ch. [2] 50, 88) regarded this substance as a hydrate of P, and Mulder (J. Ph. 23, 20) as a compound of oxide with hydride of P. When melted in large quantity and allowed to cool slowly, fairly large dodecahedral and octahedral crystals separate (Hautwein a. Buchner, Kastn. Arch. 10, 127, 504; Whewell, C. N. 39, 144; Hermann, B. 6, 1415). At ordinary temperatures P is as soft as wax; when cooled it becomes brittle. Exposed to light, P soon becomes yellow and then red on the surface. In a vacuum tube, or in a tube filled with an indifferent gas, P easily sublinies in colourless, transparent, very lustrous crystals (Hermann, B. 6, 1415; Mitscherlich, B. B. 1855. 409; Blondlot, C. R. 63, 397; Desains, C. R. 23, 149). Melted P often remains liquid many degrees below its m.p.; this is shown especially when P is melted by warming with alcoholic KOH solution, or when a solution of P in CS₂ is gradually evaporated under water (H. Rose, P. 32, 469; Kallhofert, J. pr. 50, 1). In some cases P remains liquid at c. -15°. P may be obtained in finely-divided particles by melting it under water, and shaking carefully in a flask until the P solidifies; if pure P is melted mass until the r solutions; if pure r is metted under a solution of sugar, gum, dextrin, NH₂Cl, (NH₃)₂CO₃, &c., and shaken until it solidities, the P is obtained in a state of extremely fine division (Casaseca, J. Ph. 16, 202; Blondlot, J. 1865, 126; Schiff, A. 118, 88; also A. Suppl. 4, 37). P is slightly sol. water, alcohol, ether, ethereal and fatty oils, and hot conc. acetic acid (Vulpius, Ar. Ph. [3] 13, 38). Water shaken with P loses the smell and taste of P, and ceases to glow in the dark when it has been exposed to air for a time (Müller, B. 3, 84). P is very soluble in CS2, S2Cl2, and liquid P2S.

P volatilises in water-vapour, even at the ordinary temperature; when P is distilled in steam and the distillate is cooled rapidly, the P is obtained as a white snow-like mass (Remsen a. Kaiser, Am. 4, 459); it is also often obtained in this form by distilling crude H1Aq containing

P (Hell, J. 1883. 312).

P oxidises very easily; slowly when exposed to low temperatures, and more rapidly as the ignition temperature, 60°, is approached. When P is burnt in air or O it emits very bright yellow-white light, and much heat is produced. But if H is passed over slightly warmed P, or if a stream of the warm gas is charged with a very little P, the issuing gas glows with a very feeble greyish white light, scarcely visible in daylight; the temperature of this flame is very low: if the H is ignited an emerald-green cone appears in the interior of the H flame (for spectrum of this green cone v. Christofle a. Beil-stein, C. R. 56, 399; Salet, A. Ch. [4] 28, 56). The glowing of P in the dark was formerly supposed to be due to the evaporation of the P (Corne, J. Ph. [5] 6, 17; Marchand, J. pr. 50, 1). It was shown that P glows in an indifferent gas only when small quantities of O are present; also that P neither oxidises nor glows in pure O at the ordinary pressure, but only when the O is diluted with an indifferent gas or the pressure is

diminished; and also that the glowing is stopped by the presence of H.S. PH., SO., CS., Br. Cl., N.2O., NO., &c. (Fischer, J. pr. 85, 842; 39, 48; Schrötter, J. pr. 58, 158; Müller, B. 3, 84; Joubert, C. R. 78, 1853; Deschamps, C. R. 52, 355; Müller-Erzbach, B. 12, 2130; Chappuis; Bl. [2] 35, 419; cf. Thorpe, 'On the Glow of Phosphorus,' N. 41, 523). Much work has been done to determine whether ozone or H.O., or both, is formed when P oxidises in moist air; the question is not yet finally settled (McLeod, C. J. 37, 118; Kingzett, Č. J. 37, 792); Leeds (N. Y. Acad. of Sciences, 1, 363, and 3, 150) has given a full index to the memoirs on the subject. Schmid (J. pr. 98, 414) determined that ozone is not formed when P oxidises in dry O. P is extremely poisonous; the lethal dose for adults is from 2 to 5g. Burns with P are very dangerous; the parts should be rapidly and thoroughly washed with dilute bleaching powder solution.

The atomic weight of P has been determined, (1) by ppg. Ag and Au solutions by P and determining the ratio of Ag:P and Au:P (Berzelius, G. A. 53, 433; P. 8, 17); (2) by finding the Ag needed to ppt. Cl from PCl₂ (Pelouze, C. R. 20, 1047; Dumas, A. Ch. [3] 55, 174); (3) by oxidising red P in O to P₂O₃ (Schrötter, J. pr. 53, 435); (4) by analysing and determining V.D. of PCl₃, PF₃, &c.; (5) by measuring S.H. of P.

Determinations of the S.G. of P vapour made by Dumas, Mitscherlich, and Deville a. Troost at temperatures from 500° to 1000° gave numbers agreeing with the molecular wt. P₄=124. Biltz a. V. Meyer (B. 22, 725) obtained the values 52·5 at 1480°, 46·7 at 1680°, and 45·5 at 1700° for V.D. of P, showing that at a white heat the mol. formula is probably P₂ (V.D. = 31).

The mol wt. of ordinary P in solution in C_1H_3 was determined by Paterno a. Nasini (B. 21, 2153) by the cryoscopic method; values were obtained between P_2 and P_4 . Hertz, using the same method and the same solvent, obtained the value $124 = P_4$ (Z. P. C. 6, 358). Beckmann also found $124 = P_1$ for P in solution in CS_4 by the method of raising of boiling-point of the solvent (Z. P. C. 5, 76).

The action of light, heat, or electricity on P changes it into allotropic red P. Light affects the change whether the P be in air or another gas, or in vacuo, whether water be present or not (Schrötter, W. A. B. 1, 130, 8, 241; 9, 414), at temperatures as low as -14° , and whether the P be solid or dissolved in CS₂ (Corenwinder, A. Ch. [3] 30, 242; Lallemand, C. R. 70, 182). For an account of the action of tropical sunlight on P in CS, v. Pedler, C. J. 57, 599. The action of heat begins at c. 215° at the ordinary pressure; diminution of pressure causes a slackening of the rate of change, and the action stops at 393 mm. pressure, temp. being 215°. The change is complete by heating to 260° for c. 8 days; at 800°, in a scaled tube, it is finished in a few minutes (Schrötter, *l.c.*; Hittorf, P. 126, 193; V. Meyer, B. 15, 297; cf. Dissociation, vol. ii. p. 891). The change is accomplished by electricity by passing the current through a little P in a closed tube with Pt wires fused into the ends (Grove, C. J. 16, 269; Geissler, P. 152, 171). Hittorf (P. 126, 198) regards the action as due

to the heating of the P vapour by the current. Certain reagents also effect the change: c.g. heating with a very little I (Brodie, J. pr. 58, 171); or heating a solution of P in CS, with I (Corenwinder, A. Oh. [8], 30, 242; Lallemand, C. R. 70, 182), but Rüdorff (P. 128, 463) says the product is a hydride of P. In the change of 62 g. ordinary P into red P c. 7,100 g.-units of heat are produced; and there is a contraction of volume (v. Petersen, Z. P. C. 8, 601).

2. Amorphous of red phosphorus is a dull, dark carmine, odourless, tasteless powder, which becomes darker on heating, and black when boiled with KOHAq. It is brittle, and shows no trace of crystalline form. Amorphous P is heavier, and conducts electricity much better, than crystalline P, although its conductive power is very small compared with the metals (v. data at beginning of this article). Amorphous P does not melt when heated to redness in a sealed tube (Hittorf, l.c.); vapour is formed in the tube, and on cooling this solidifies as crystalline P, but the unvapourised portion remains amorphous. When distilled, amorphous P becomes crystalline; the action begins at c. 260° (Schrötter, l.c.). The process, like the reverse change of crystalline into amorphous P, is essentially one of dissociation (v. Dissociation, vol. ii. pp. 391-3). Amorphous P takes fire at c. 250°-260° (Hittorf, Schrötter, l.c.), but active combustion begins at c. 300°; it does not oxidise in dry air, but in presence of moisture oxidation proceeds slowly, with the smell of ozone and the formation of an acid liquid (Personne, C. R. 45, 113; Wilson, Ph. 17, 410; Pedler, C. J. 57, 599). Red P does not glow in the air; it is not poisonous (De Vrij. J. 1851, 313). This variety of P is insoluble in the menstrua which dissolve ordinary P; boiling turpentine, and a few liquids of high Soiling-points, dissolve a fittle and change it into ordinary P.

3. Crystalline metallic phosphorus is described by Hictorf (P. 126, 193) as forming long, black, thin, rhombohedral crystals which appear red in transmitted light; S.G. 2:34 at 15:6°; less volatile than amorphous P; heated in a sealed tube drops of ordinary P appear at c. 358°. It is doubtful whether this is a distinct variety of P; it does not seem to have been obtained free from Pb (for preparation, v. ante). According to Troost and Hautefeuille (C. R. 78, 748), the S.G. and heat of combustion of red P change continuously with temperature; at 580° ruby-red crystals appear, which have the S.G. of Hittorf's metallic P.

Thénard observed that P became black when heated and suddenly cooled (Gm. K. [6th ed.] i. 2, 102); some experimenters claim this to be a special variety of P (v. Reichardt, Ar. Ph. [3] 9, 442; P. Thénard, C. R. 95, 409); according to others it contains fogeign substances. Blondlot obtained it only when a trace of Hg was present (C. R. 70, 856; 78, 1130); Ritter found the presence of As necessary (C. R. 78, 192).

(C. R. 70, 856; 78, 1130); Ritter found the presence of As necessary (C. R. 78, 192).

Napoli (C. R. 25, 369) thought that a special yellow modification of P was produced by keeping freshly-melted ordinary P under water.

The atom of P is trivalent in most gaseous molecules, e.g. PCl₂, PH₂, PF₃, &c.; it is pentavalent in the gassous molecule PF₂. P acts as a non-metallic element; its oxides are acidic, although Vot. IV.

some of them combine with less acidic oxides to form salt-like compounds. P is closely related to As, Sb, and Bi, and also to N, V, Nb, Di, Er, and Ta; those elements form Group V. For a detailed consideration of the chemical relations of P v. Nithoorn Group of Elements, vol. iii. p. 571. The specific volume of P at its b.p. is 20-21 (Pisati a. de Franchis, B. 8, 70; Ramsay a. Young, C. J. 39, 50); the specific volume of P in combination is c. 25-3 (Thorpe, C. J. 37, 233).

Reactions and Combinations .- 1. P combines with oxygen to form P.O, P.O., and P.O.; the reaction begins at ordinary temperature with crystalline P, and at c. 250'-260° with amorphous P. (For more details v. Phospical's, exides of, p. 138.) P does not combine with pure O at the ordinary pressure, but only when an indifferent gas is present, or the pressure is diminished (for references v. Properties of P, p. 128). The combination of P in O is arrested in proportion to the dryness of the O (Baker, C. J. 47, 349; Pr. 46, 1). Amorphous P does not oxidise in dry air, but the oxidation proceeds slowly in moist air. Ordinary Poxidises readily in moist air; it is not yet finally settled whether or not ozone is produced (v. McLeod, C. J. 37, 118). In moist air HaPOs is formed; this maybe a direct product of oxidation, or it may result from the reduction of H_sPO₄ formed by the direct oxidation of the P (v. Schönbein a. Bohlig, J. 1863. 167; Blondlot, C. R. 66, 851; Stiassay, D. P. J. 199, 414).-2. P is easily changed to P2O3 by oxidising agents, e.g. HNOn Cro, KNO, &c. A mixture of P and KClo explodes violently when struck or rubbed; the explosion is less violent with amorphous P. Amorphous P is inflamed when rubbed with Amorphous P is infinited with CrO₃, PbO₂, Pb₃O₄, HgO, K₂Cr₂O₇, or Ag₂O, and when heated with MnO₂, CuO, or KNO₃.—
3. P combines with sulphur, the halogens, and many non-metals when heated with these. reactions occur at lower temperatures, and more rapidly, with ordinary than with amorphous P, yet amorphous P combines with Br and Cl at the ordinary temperature .- 4. P decomposes solutions of salts of copper, silver, and some other metals, with separation of the metal, which often combines with the P .- 5. Boiling water is slightly decomposed by P in presence of air, with formation of PH3, H3PO3Aq, and H3PO4Aq (Cross a. Higgin, C. J. 35, 254); at 250° the reaction is more rapid (Schrötter); with amorphous P the action is slow (C. a. H.). - 6. Concentrated hydrochloric acid is decomposed by P at 140°, with formation of PH, and H.PO.Aq (Oppenheim, Bl. [2] 1, 163).-7. Hydriodic acid reacts with P to form PH I and PI; hydrobromic acid reacts at 100°-120° to produce PH,Br (Damoiseau, C. R. 91, 883).—8. Chlorosulphonic acid [SO, OH.Cl] reacts explosively with ordinary P at 25°-30°, and more slowly and at a higher temperature with amorphous P, to form SO₃, HCl, and H₂PO₄ (Heumann a. Köcklin, B. 15, 416) .- 9. Sulphuryl chloride [SO,Cl,] produces PCl, and SO₂; the reaction is violent, even with amorphous P (H. s. K., B. 15, 1736).—10. Adie (C. J. 59, 230) describes the action of sulphur trioxide on P as producing \$P_0_280_.—11. With boiling solutions of alkalis P forms PH, and alkali salts of H_PO_ P left for a long time in

contact with ammonia solution probably forms P hydride and NH, phosphite (v. Blondlot, C. R. 57, 1250; Commaille, C. R. 68, 263; Flückiger, 71, 1200; Commande, C. R. 03, 200; Pittanger, 1, 1863, 171). Red P is not acted on by NH₂Aq (F., L. c.),—12. Heated with the alkaline earths P forms phosphides and phosphates.—13. When P is strongly heated with anhydrous alkali carbonates C is separated. For an account of the technical applications of P v. DICTIONARY OF APPLIED CHEMISTRY; for description of the methods of testing for P and estimating it a manual of analysis must be coffsulted.

Phosphorus, acids of. The phosphoric acids are described under that heading (p. 124), the other soids under the heading Phosphorus, oxy-ACIDS OF, AND THEIR SALTS (p. 149). For phosphamic acids v. p. 105, and for thiophosphamic acids v. Thiophosphoryl Chloride, Reaction No. 7, p. 148.

Phosphorus, bromides of P and Br combine violently; two products of the reaction have been isolated, PBr, and PBr. These formulæ are probably molecular.

PHOSPHORUS TRIBROMIDE, PBr. (Phosphorous bromide). B.P. = 172.9° at 760.2 mm. (Thorpe, C. J. 37, 835). S.G. 292311 (T., l.c.). Does not solidify at -18.6°. A colourless liquid, with very penetrating odour; fumes in the air. PBr. is formed by the direct union of P and Br. If P is added to Br, the Br must be kept in a freezing mixture, and the P must be added in extremely small pieces until a colourless liquid is obtained; the process is dangerous. Lieben (A. 146, 314) recommends to pass CO, through slightly warmed Br, to lead the gas over small pieces of dry P, and to distil the liquid thus produced after it has stood for some days. Schorlemmer uses amorphous P. The P is placed in a flask connected with an inverted condenser, and having a dropping funnel passing through the cork. Br is added drop by drop from the funnel: the first few drops combine, with a production of flame, but after a little the Br may be added more freely; the PBr, is distilled from the excess of P (v. also Pierre, A. Ch. [8] 20, 5; Kekulé, A. 130, 16; Löwig, Gm.-K. i. 2, 334).

PBr, is not acted on by O; reacts with S to form PSBr, (Gladstone, P. M. [3] 35, 345); Cl forms PCl, and Br; HgCl, forms PCl, and HgBr.; H₂S produces P₂S₂ and HBr. PBr, is decomposed slowly by cold water, rapidly at 25°, to HBrAq and H₃PO₂Aq (Löwig, *l.c.*). P and I dissolve in PBr.

PHOSPHORUS PENTABROMIDE, PBr, (Phosphoric bromide. Perbromide of phosphorus). Produced by adding excess of Br to PBr, stirring well with a glass rod, and after a time removing the excess of Br by warming very gently in a stream of dry CO₂. Also formed by action of Br on FOL, in presence of a little I (Gladstone, P. M. [8] 53, 345). PBr, forms a citron-yellow solid; fumes in the air; melts to a red liquid when gently warmed, which solidifies again to rhom-boidal crystals, which are yellow if cooling has been rapid, and red if cooling has been slow. The red crystals become yellow when rubbed (Baudrimont, Bl. 1861. 118); at a higher temperature (below 100°) gives red vapours that condense to yellow needles. PBr, is separated at c. 100°

into PBr, and Br, which re-combine on cooling. (Ogier, C. R. 92, 83) gives the following heats of formation: [P,Brs] = 63,000 from liquid Br; Br; in each case solid PBr, is formed.

Reactions.—1. Heated to 200° in oxygen,

PBr, inflames with formation of P₂O₃ (Baumstark, A. 140, 75).—2. Neither hydrogen nor sulphur reacts in the cold with PBr₂.—3. Chlorine forms PCl, and Br; iodine produces PBr, and IBr. -4. In moist air, POBr, is formed (q. v.).-6. A little water produces HBr and POBr.; with much water HBr and H3PO, are formed.--6. PBr, reacts with hydroxides to substitute OH by Br; the reaction is similar to, but not so energetic as, that of PCl₃.-7. Hydrogen sulphide forms PSBr₃ and HBr.- 8. Phosphorus hydride forms at first PBr, and then also P and HBr.-9. Hydriodic acid has no action a dry boric acid forms some BBr. (Gustavson, B. 3, 426); dry oxalic acid produces POBr, HBr, CO, and CO. 10. Antimony sulphide produces SbBr, and PSBr, (Baudrimont, Bl. 1861. 118) .- 11. With many metals at high temperatures. PBr. produces phosphides and bromides.

Combination. - With ammonia to PBr, 9NH, Prepared by passing dry NH, into a solution of PBr, in CCl, (Besson, C. R. 111,

Phosphorus, bromochlorides of. compounds of P, Br, and Cl are formed by the reaction of PCl₂ with Br. PBr₂Cl₃, PBr₄Cl₄, or PBr₈Cl₄ is produced according to the relative quantities of PCl, and Br used; and from one or other of these the compounds PBr,Cl₂ and PBrCl, are obtained. According to Stern (C. J. 49, 815) PBr.Cl. is formed, and on addition of . more Br the compound PBr, Cl, is produced, and unites with Br to form PBr, Cl2; the whole of the Cl in PCl, cannot be thus replaced by Br (Michaelis, B. 5, 9, 411; Wichelhaus, A. Suppl. 6, 277; Stern, C. J. 49, 815; Geuther, J. Z. 10, 128; Michaelis a. Geuther, J. Z. 6, 242; Prinvault, C. R. 74, 868). Michaelis regarded PBr.Cl. and PBr,Cl, as compounds of PBr,Cl, with Br, and 3Br, respectively; Prinvault looked on PBr,Cl, as PBr,Cl, EPCl, and PBr,Cl, and PBr,Cl, as PBr,SBrCl and PBr,BrCl, respectively. Against Prinvault's view it was urged by Michaelis that if the compounds contain PBr, they must whereas the products are POCl₃, SBr, and Br; but Geuther showed that POBr₃ reacts with BrGl to give POCl, and Br. Geuther regarded the compounds as containing trivalent Br atoms.

PHOSPHORUS DIBROMOTRICHLORIDE, PBr,Cla Yellow-red crystals, melting at 35°; obtained by gradually adding 160 pts. Br to 187.5 pts. PCl. and keeping in a closed tube in a freezing mixture for some time (M.). Addition of 18 pts. water reacts thus (G. a. M.): 3PBr.Cl, +3H.O = 2POCl, + POBr, +3HCl +3HBr. It 8O, is passed into the contents of the tube, SBr. and POCI, are formed (M.)

PHOSPHORUS TETRABROMOTRICHLORIDE PBr,Cl. Large dark-red crystals with a blue sheen; formed by adding Br slowly to PCl, till two layers are produced, the lower of which is dark and oily, and then adding PBr.Cl, until the lower layer solidifies (G.). Also produced by warming PBr, with PCl, to 40°;

 $4PBr_a + 6PCl_a = 5PCl_a + 5PBr_aCl_a$ (G.), when heated PBr.Cl, melts and separates into two layers, which unite again on cooling. A little H₂O produces POCl₂, POBr₂, HCl, HBr, and Br: much H.O forms H.PO., HCl, HBr, and Br; SO, produces POCl, SBr, and Br.

PHOSPHORUS OCTOBROMOTRICHLORIDE PBr.Cl. Brown needles, melting at 25°. Formed by adding 42 pts. Br to 1 pt. PCl, (i.e. in the ratio 8Br: PCl,), heating to 65°, and allowing the oily liquid to cool to c. 4° much heat is produced in the reaction (P.). Geuther (I.c.) says the compound is also produced by adding BrCl to PBr, in the ratio PBr. : 3BrCl.

PHOSPHORUS HEPTABROMODICHLORIDE PBr, Cla. Prismatic crystals. Obtained by rapidly distilling the preceding compound at a little above 90° (P.); also by dropping PCl, into Br until two layers are formed, and allowing to stand. Soluble in PCl3.

PHOSPHORUS MONOBROMOTETRACHLORIDE

PBrCl. According to Prinvault (l.c.) this compound is obtained, as yellow crystals, by heating to boiling a solution of the preceding compound in PCl₃, also by the reaction of PCl₃ with BrCl. P. says that PBr₈Cl₃ and PCl₃ react in accordance with the equation PBr,Cl, + PCl, = PBr,Cl, + PBrCl,.

Phosphorus, bromofluoride of, PBr.F. liquid, which fumes in the air, and is violently decomposed by water; also decomposed easily by heat to PBr, and PF,; formed by passing PF₃ into Br (Moissan, C. R. 100, 1348).

Phosphorus, bromonitride of, PBr.N. This compound is said to be formed by heating the product of the action of NH, on PBr, in a sealed tube, to 250°-275°, with twice its weight of PBr, for twelve hours, and then heating the resulting aubstances under reduced pressure, when PBr_s sublimes, and then at 200° a white crystalline sublimate of PBr_N is formed; the compound is purified by resubliming in vacuo. The crystals melt at 1880-190°; sublime at 150° in vacuo; sol. ester, less sol. CS₂ or CHCl₂, insol. water (Besson, C. R. 114, 1479).

Phosphorus chlorides of. P and Cl com-

bine directly and easily, with the production of light and much heat. Two compounds are thus produced, PCl, and PCl,; these formula are molecular. According to Donny a. Mareska (C. R. 20, 717), and Dumas (A. Ch. [3] 55, 172), liquid Cl surrounded by solid CO2 combines with P.

PHOSPHORUS TRICHLORIDE PCl, (Phosphorous chloride). Mol. w. 13707. Boils at 75.95° at 760 mm. (Thorpe, C. J. 37, 333; v. also Pierre, A. Ch. [3] 20, 5; Haagen, P. 131, 122). S.G. ⁰⁰/_{x0} 1·61275 (Thorpe, l.c.); V.D. 70·6 (Dumas, A. Ch. [8] 55, 172). S.H. of vapour 1347, equal weight of air = 1; 64, equal vol. of air = 1 (Regnault, J. 1863. 85). μ for H line a = 3222; $\frac{\mu - 1}{d}$. Mol. w.

= 44.3 (Haagen, P. 131, 122). H.F. [P,Cl*] = 75,300 (Th. 2, 408; formation of liquid PCl, Regnault (J. 1863, 65) gave the vapour pressures of PCl, in mm. of Hg as follows:—87.98 at 0°, 62.68 at 10°, 100.55 at 20°, 155.65 at 30°, 233.78 at 40°, 841-89 at 50°, 485-63 at 60°, 674-23 at 70°.

Formation.—1. By direct union of P and Cl.

2 By reaction of P with HgCl, FeCl, CuCl,

ICl., S₂Cl., or SeCl. (Gm.-K. 1. 2, 390).—3. By reaction of Cl or HgCl. with PBr, or PI, (l.c.).— 4. By decomposing PCl, by heat sided by H, P, PH, I, HI, S, or one of several metals. 5. By heating HPO, with NaCl (*Gm. K.*, *l.c.*).—6. By heating Na, HPO, with NH, Cl (H. Rose).—7. By heating P with conc. HClAq (Oppenheim, Bl. [2] 1, 163).—8. By passing POCl, through a tube filled with glowing charcoal (Riban, C. R. 95, 1160).

Preparation. About 500-600 g. P, in pieces about 1 inch long, are dried quickly, twice, between filter-paper, and placed in a dry retort of c. 1 litre capacity, through the neck of which a stream of dry CO₂ is kept passing. The beak of the retort is now passed into a well-cooled receiver, and the tubulus is connected with an apparatus which is evolving dry Cl. The tube through which the Cl passes into the retort is fixed somewhat loosely in the cork, so that it may be moved up or down easily. The retort is placed in warm water until the P is melted: after the action has fairly begun, the heat produced suffices to keep the P molten. A large basin with cold water is kept beneath the retort in case the latter should break. The reaction is regulated by moving the tube from the Cl apparatus near to, or away from, the surface of the P; if this tube is too near the P, the heat of the reaction vaporises much of the P, which then condenses in a reddish layer in the upper part of the retort; if the delivery-tube is too far from the P, solid PCI, forms and deposits on the upper part of the retort in yellow crystals. As the reaction proceeds, pieces of red P appear here and there in the retort. Towards the end much red P is formed; this must be heated carefully with a lamp, a process in which the retort is apt to be cracked. The distillate is digested with a little P for a few days, to decompose any PCl,, and then redistilled from a retort heated on a water-bath (Donny a. Mareska, C. R. 20, 717; Dumas, A. Ch. [3] 55, 172). Thorpe (C. J. 37, 333) recommends to heat red P in dry Cl; he says that the reaction is very regular, and that large quantities of PCl, may be prepared thus with great ease and rapidity; the red P should be washed with water, then with alcohol, then with ether, and dried at a gentle

Properties .- A clear, colourless, highly refractive, liquid, which can be vaporised without decomposition in absence of moisture; fumes in air with decomposition; does not redden dry blue litmus paper; vapour has an acrid smell and excites tears. Does not solidify at -115° (Natterer, P. 62, 133). Does not conduct electricity. Dissolves P; also I (Gladstone, P. M. [3] 35, 345). Mixes with C.H., Et.O. CHCl. and CS2. In a gas-flame or alcohol-flame, PCl, burns brightly. Sinks in water and then begins to decompose to H,PO,Aq and HClAq; if a little warm water is used, amorphous P separates. Slowly decomposes in the dark to PCl, and P (Casselmann, A. 83, 247). Combines with Cl to form POl. Not acted on by O at ordinary temperatures; POCl is slowly formed at b.p. of PCl. POCl, is formed by action of ozone and various O compounds which readily part with O (v. Reactions).

Testing PCL, for POCL .- PCl, has little ac-

tion on zinc-dust at ordinary temperatures; POCl₁, produces P₂O₂ and Zn phosphide, which is decomposed by H₂O, giving inflammable P hydride. To apply this reaction, a few drops of the liquid are added to a little zinc-dust in a test tube, and then a few drops of water; if POCl₂ is present, small bubbles of gas are given off, and take fire in the air (Deniges, Bl. [3] 2, 787).

Reactions.—1. Water produces H₂PO₃ and

HCl; the reaction proceeds somewhat slowly. If a little warm water is added to PCl, amorphous P separates at the product of a secondary reaction —3 H₁PO₂Aq + 2PCl₁ = 3HPO₃Aq + 6HClAq + 2P (Michaelis, B. 8, 704); but cf. Geuther, J. Z. [2] 3, 2nd Suppl. 116) .- 2. Oxygen does not react at ordinary temperatures, but POCl₃ is slowly formed at b.p. of PCl₃ (Michaelis, J. Z. 6, 93; Remsen, Am. S. [3] 11, 365).—3. Ozone rapidly forms POC1, (Remsen, Lc.).—4. Polarsium, chlorate produces POC1,—5. Sulphfir trioxide reacts violently, forming POC1, and SO. (Michelis, J. Z. 6, 239; 7, 110; Armstrong, J. pr. [2] 1, 255; cf. Rose, P. 44, 304).—6. Selenion dioxide produces POCl, and Se at 110°; if the SeO, is in excess, SeCl, and P.O. are also formed; SO, has no action at 140° (M., l.c.). -7. Heated in a closed tube at 130° with arsenious oxide, forms As, AsCl₃, and P₂O₃ (Michaelis, l.c.). --8. Thionyl chloride forms PCl₃, POCl₃, and PSCl₃. Chromyl dichloride produces POCl, P2O, PCl, and CrCl, 9. Nitrogen trioxide or pentoride reacts with strongly cooled PCl₃ to form NOCl, P₂O₅, POCl₃, and P₂O₅Cl₄ (Geuther a. Michaelis, B. 4, 766). 10. Many metallic oxides withdraw Cl from PCl. forming metallic chlorides; PbO forms Pb and Pb(PO₃) besides PbCl₂—11. Many metallic sulphides when heated with PCl₃ react to form P₃S₂ and metallic chlorides; e.g. K₂S, BaS, CaS, Sb₂S₃, PbS, &c. (v. Gm.-K. i. 2, 320). - 12. Sulphur reacts at c. 130° with production of PSCI, (Henry, B. 2, 638).—13. Antimony forms SbCl, and P (Gm.-K., l.c.).—14. Red-hot iron filings produce Fe phosphide and FeCl, (Gm.-K.).

15. Zinc, at 100°, forms ZnCl, and P (Most, B.
18, 2029).—16. Platinum and silver are not acted on by PCl_s (Gm.-K.).—17. Sulphuric acid reacts slowly in the cold, rapidly when hot, to form SO₂, HCl, P₂O₃, and SO₂, OH, Cl (Michaelis, J. Z. 6, 239).—18. Phosphorous acid produces P.O. (Nacquet's Chem. German ed. 1868. p. 218). 19. Hydriodic acid reacts at the ordinary temperature, forming PI, and HCl (Hautefeuille, Bl. [2] 7, 198, 200, 203). 20. PSCl₂ and PCl₃ are formed by heating for some hours at 160° with sulphur chloride. - 21. Iodine pentabromide is said to form ICl, and PBr, -22. Phosphorus hydrids produces HCl and solid P₂H (Besson, C. R. 111, 972). SbH, is said to be without action (Mahn, Z. [2] 5, 729).—23. Heated with hydrogen sulphide, HCl and P.S. are formed (Baudrimont, A. Ch. [4] 2, 5).—24. Anmonia seems to form various compounds which have not been fully examined (v. Phospham, p. 104).— 25. Passed over heated ammonium chloride, phospham (q. v.) is formed.—26. With many carbon compounds containing hydroxyl, PCl,

reacts to substitute Ol for OH.

Combinations.—1. With chlorine, to form PCl, (q. v.).—2. With bromins to form several bromochlorides (q. v.).—3. With iodine

to form PLCl, (v. PHOSPHORUS IODOCHLORIDE, P. 138).—4. With titanium chloride to form PCl, TiCl, (Bertrand, M. S. [8] 10, 1331); also with a few other metallic chlorides, e.g. AuCl.—5. With dry ammonia to form PCl, 5NH, (Rose; Besson, C. R. 111, 972).

PHOSPHORUS PENTACHLORIDE PCl. (Phosphoric chloride. Phosphorus perchloride). Mol. w. 207-81. Melts at 148° under pressure; boils at 160°-165°, with partial decomposition to PCl, and Cl. V.D. varies with temperature; c. 103 in un atmosphere of PCl. (v. Properties). H.F. [P.Cl.] = 104,996 (Th. 2, 408).

Formation.—1. By combining PCl, with Cl,

Formation.—1. By combining PCl, with Cl, or by the action of excess of Cl on P.—2. By reacting with PCl, on PH, S.Cl., or SOCl.,—3. By the action of SbCl., on PH, (Mahn, Z. [2] 5, 729).

Preparation.—PCl, may be prepared by the

action of Cl on P, but the PCls is apt to retain pieces of unchanged P, the presence of which may lead to violent explosions; it is, therefore, better to prepare PCl, from PCl, PCl, is placed in a strong flask with a wide neck; the flask is surrounded by a freezing mixture, and dry Cl is passed in by a wide tube which reaches almost to, but does not touch, the surface of the liquid. As the contents of the flask get semi-solid they must be thoroughly broken up by a glass rod. The whole of the PCl, is not changed to PCl, until Cl has passed for a considerable time; the change is not complete until, after closing the flask, shaking thoroughly, and allowing to stand for some time, the presence of greenish-yellow gas in the flask is quite apparent. Excess of Cl is finally removed by the long-continued passage of a slow stream of dry CO₂ (Müller, Z. 1882.

295; Gräbe, Ar. Sc. [3] 5, 477).

Properties. - A white, or slightly yellow, crystalline solid with a strong odour; crystallines in rhomble plates; fumes in moist air, with decomposition; sublimes without melting under 100°, but melts at c. 148° under considerable pressure; boils at c. 160°-165°, with partial dissociation to PCl, and Cl, which re-combine on cooling. PCl, does not conduct electricity (Gm.-K.i. 2, 390). Decomposed by O at c. 300°. Burns in a candle-flame.

Vapour density.—The S.G. of the vapour obtained by heating PCl, is less than that calculated for PCl,, and it decreases as temperature increases until it is equal to half the calculated value. Wanklyn a. Robinson (C. R. 56, 547) showed that the vapour contained free Cl, by diffusing into CO₂, and that PCl₃ was present in the residue. Deville noticed that the vapour showed the colour of Cl, and that the intensity of colour increased as temperature rose (A. 141, 147). The V.D. was determined by Cahours at different temperatures, with the following results (A. 141, 42; v. also Gibbs, Am. S. [3] 18, 277,

1):		
Temp.	S.G. (air = 1)	P.c. Dissociation
182°	5.08	41.7
190	4.99	44.3
200	4.85	48.5
23 0	4.80	67.4
250	4.00	80.0
274	8.84	87.5
288	3.67	96.2
*289	8.69	9597
800	8-65	Q7-R

The temperature whereat 50 p.c. is dissociated is c. 202°. Wurtz (B. 3, 572) showed that, making certain assumptions, the S.G. of PCl, vapour formed in an atmosphere of PCl, is c. 74-6.8, which agrees with that calculated for PCl_s, viz. 7.2.

Reactions .- 1. Heat dissociates PCl, into PCl, and Cl, which recombine on cooling (v. ante).-2. PCl, is decomposed by water to HClAq and POCl, and finally to H,PO,Aq with some HPO, Aq (Gm.-K. i. 2, 390). Thomsen gives [PCP, Aq] = 123,440 (Th. 2, 322).-3. Boric acid and antimonic hydrate react similarly to water (Gerhardt, A. 87, 66, 290; Schiff, A. 102, 111; 106, 116). Boric oxide when heated with PCl_s forms B.O., P.O., and BCl_s (Gustavson, B. 3, 426).— 4. Hydroxides generally, including carbon compounds which contain the group OH, exchange OH for Cl, with production of POCl, and chloride of the radicle before in combination with OH.— 5. Compounds containing the group SII generally react similarly to OH compounds; e.g. SH.H gives OH and PSCl₂.—6. Oxides generally exchange O for Cl.; carbon compounds containing the group CO generally also react in this way. -7. Oxygen reacts with vapour of PCl, at c. 300°, producing POCl₃, P₂O₅, and Cl (Gm.-K. i. 2, 390; Wanklyn a. Robinson, C. R. 56, 547) .-8. PCl, vapour mixed with hydrogen and passed through a red-hot tube produces HCl, PCl, and P (Baudrimont, Gm.-K. i. 2, 394) .- 9. Heated with phosphorus PCl, is produced.-10. The compound PS,Cl, is formed by distilling PCl, with 8 parts of sulphur (Gladstone, C. J. 3, 5). 11. Selenion produces Se.Cl₂ and PCl₃.—
12. Iodine forms PCl₃, and ICl which combines with part of the PCl, to produce PCl, ICl (Gm.-K., l.c.). - 13. PCl3 reacts with many metals to form metallic chlorides and PCl,; sometimes P and metallic phosphides are formed (Baudrimont, J. pr. 87, 300; 88, 78; Casselmann, A. 98, 213). Among the metals which react with I'Cl, are Al, As, Cd, Au, Fc, Pt, K, Na, Sn, and Zn. The metallic chloride formed often combines with the undecomposed PCl₃; this occurs, e.g., with AlCl₃, FeCl₄, HgCl₂, PtCl₄, and SuCl₄ (Wöhler, B. 13, 875; cf. Goldschmidt, C. C. 1881. 489) .-- 14. Phosphorus hadride produces PCl, and HCl; with excess of PH3, HCl, and are formed.-15. Antimony hydride forms PCl, SbCl, and HCl; silicon hydride acts similarly but more slowly (Mahn, Z. [2] 5, 729; ammonia forms phospham (q. v., p. 104) and nitrogen phospham (q. v., p. 104). phochloride (vol. iii. p. 570); also phosphamidoimide (q. v., p. 105; cf. also Besson, C. R. 114, 1364). 16. Sulphur dioxide produces SOCl₂ and POCl₃ (Schiff, A. 102, 111; 106, 116; Persoz a. Bloch, C. R. 28, 86; Kremers, A. 70, 297).-17. Sulphur trioxide forms S2Cl2O, and POCI, (Schiff, l.c.; Michaelis, J. Z. 6, 235, 240, 292; Williamson, Pr. 7, 11).-18. Selenion dioxide when distilled with PCI, forms POCI, SeCl., and P₂O, SeOCI, being formed as an intermediate product (Michaelis, Z. [2] 6, 465).— 19. Phosphoric oxide produces POCl, 20. Boric oxide reacts slowly when heated to c. 140° with PCl,; BOCl, is probably formed, and on heating more strongly BCl, and B,O,P,O, remain (Gustavson, B. 3, 426).—21. Nitrogen dioxide produces NOCl and POOl, (Gm.-K. i. 2, 390).—
22. Silicon dioxide forms POCl., and SiOl, which

combines with the excess of PCl, (Weber, P. 107, 875) .- 23. Vapour of PCl, reacts with many metallic oxides, when these are strongly heated, to form POCl,, and metallic chlorides which frequently combine with undecomposed PCI,. The following react in this way—Al₂O₃, As₂O₄, and As₂O₅ (Hurtzig a. Geuther, A. 111, 159; Michaelis, J. Z. 6, 239), [no reaction with Sb.O.; Schiff, A. 102, 111], CdO, Cr.O., Fe.O., MnO., MoO., Schiff, l.c.), SnO, TiO., (Weber, P. 107, 375; Tittscheff, A. 141, 111), WO., (Gerhardt a. Chiozza, C. R. 36, 1050; Schiff l.c.).—24. Phosphorus sulphide forms PSCl, (Weber, P. 107, 375; Gm.-K. i. 2, 390) .- 25. Carbon disulphide does not react at 100° (Hofmann, A. 115, 264); at 200° PSCl, 'a produced (Carius a. Fries, A. 112, 193), and CCl. (Rathke, Z. [2] 6, 57). - 26. Many metallic sulphides when heated are decomposed by vapour of PCl, with formation of PSCl, S.Cl, and metallic chloride; the following react in this way—sulphide of As, Ba, Bi, Cd, Ca, Pb, Na, Sn. Zn (Weber, *l.c.*; Baudrimont, *l.c.*).— 27. Antimony selenide and lead selenide form SeCl, which forms a double compound with the excess of I'Cl₅. - 28. Hydriodic acid produces I'Cl₃, HCl, and I (Wurtz, Gm.-K., l.c.); hydrobromic acid is without action (Gladstone, C. J. 3, 5); syrupy phosphoric acid solution reacts slowly, the vapours of this acid do not act (Gerhardt, A. 87, 66, 290; Schiff, A. 102, 111; 106, 116; Persoz a. Bloch, C. R. 28, 86).— 29. Conc. nitric acid reacts energetically, forming POCl3 and HCl.-30. Sulphuric acid forms SO. OH.Cl, HCl, and HPO, and Scl.O, as the result of a secondary reaction (Michaelis, J. Z. 6, 235, 240, 292; Williamson, Pr. 7, 11; Baumstark, A. 140, 75) .- 31. Many metallic salts react with PCl,; KNO, gives NOCl and POCl, (Nacquet, Bl. 1860); sulphites form SOCI, (Buchanan, B. 3, 485); Agl produces AgCl and probably a fluoride of P (Pfaundler, W. A. B. 46, 258); KClO, gives POCl.; KSCy forms PSCl., S.Cl., and PCl.; Na.HPO, gives H.,PO, and HCl; haloid salts of the alkalis, and also KCy and K, FeCy, are not acted on by PCl,

Combinations. -1. With iodine chloride to form PCl, ICl (Gm.-K. i. 2, 390). - 2. With selenion tetrachloride to form SeCl., 2PCl. -3. With many metallic chlorides (cf. Reactions, Nos. 13 and 23). These compounds are solids, which sublime with partial decomposition when heated, and are decomposed by water (Baudri-mont, J. pr. 87, 300; 88, 78; Weber, ibid. 77, 65; Casselmann, A. 83, 258) .- 4. With ammonia to form PCl, SNH,; produced by slowly passing dry NH, into a solution of PCl, in CCl, (Besson, C. R. 111, 972; 114, 1264).

Phosphorus, chlorobromides of, v. Phosphorus

Phosphorus, chlorofluoride of, PCl₃F₂. 175 07. V.D. 78. Poulenc (C. R. 113, 75).

Preparation .- Tw stoppered flasks of c. 500 c.c. capacity are connected by a bent tube, which passes through the stoppers; one flask is filled with dry Cl, and the other with dry PF.; that containing PF, is connected with a bulb full of Hg. which can be caused to flow into the flask and so force the PF, into the flask full of Cl. The PF, is slowly driven into the other flask, and the PCl.F, thus formed is kept in contact with Hg for some days (without being shaken

with the Hg, else some PF, may be decomposed) to remove traces of Cl.

Properties — A colourless gas, with very irritating odour; incombustible; liquefied at -8° at ordinary pressure; absorbed and decomposed by water; heated to c. 250° gives PF₂ and PCl₃, also decomposed in the same way by electric sparks.

Reactions.—1. Heat produces PF, and PCl,; the action proceeds at c. 250°.—2., Electric sparks also produce PF, and PCl,.—3. Heated with sulphur to c. 115°, PSF, and S₂Cl₂ are formed.—4. Heated with phosphorus to c. 120° PF, and PCl₃ are formed.—5. Several metals when heated to c. 180° produce metallic chloride and PF, e.g. Al, Fe, Pb, Mg, Ni, and Sn; Hg exerts a slight action at ordinary temperatures, and acts rapidly at 180°; Na seems to absorb PCl₃F₂ entirely.—6. Water reacts rapidly; if a little water-vapour is mixed with PCl₄F₂ the products are POF, and HCl; it the gas is passed into water, H,PQ,Aq, HClAq, and HFAq varo formed.—7. Absorbed by alcohol, with formation of a compound not yet examined.—8. Ammonia is absorbed at ordinary temperature, forming a white solid, which is probably PF₃(NH₂)₂.

Phosphorus, chloro-iodide of, v. Phosphorus

"дороспьовире, р. 138.

Phosphorus, chloronitride of, v. Nitrogen Phosphoculoring, vol. iii. p. 570. Besson (C. R. 114, 1479) recommends to prepare PCl₂N by forming a layer of PCl₃ on the sides of a large flask, by acting on PCl, with Cl, then to heat the PCl, with NH, till it is superficially saturated, and then to heat under reduced pressure.

then to heat under reduced pressure.

Phosphorus.compounds of, with hydrogen and oxygen. Those compounds of P, H, and O, which are acids, are described in the articles Phosphoric ACIDS (p. 124), and Phosphorus, oxyacids of, and THEIR SALTS (p. 149); but two compounds which have been described by Gautier will find a place here. Gautier (C. R. 76, 49) says that the compound P.HO is formed by heating crystallised H.PO, with 5 or 6 times its weight of PCl, to 79°, washing with water, and drying at -10° ; at between 80° and 100° the products of the reaction are H₂PO₄, HCl, and amorphous P. This compound is described as an amorphous yellow powder; unchanged in air when dry, but oxidised slowly when moist; insoluble in most menstrua: burns when heated in air to c. 260°: burns explosively when heated with CuO; unchanged at 240°-250° in CO, but evolves PH. at 265°, and at 350°-860° ordinary P distils off not acted on by dilute acids; oxidised by ordinary HNO₂Aq; conc. H₂SO₄ evolves SO₂ at c. 200°; decomposed by H₂O at c. 170° to H₂PO₂Aq, H₂PO₃Aq, and PH₃; reacts with dilute alkali solutions; NH, combines to form a very unstable brown substance. Gautier (C. R. 76, 173) described another compound P_bH₃O; obtained by adding PI2, little by little, to H2O at 80°-90° allowing the yellow solution to deposit a flocculent pp., washing this with warm water, and drying in vacuo. If water is added slowly to PI₂ the products are HIAq, H₂PO₂Aq, and H₂PO₂Aq. P₂H₃O is described as a pure yellow solid; amorphous, or perhaps showing traces of crystalline form; tasteless and odourless; insoluble in all menstrua; oxidises in air when n.oist, when dry oxidises slowly at 100°; oxidised

violently by HNO.Aq; evolves SO. from H.SO.; gives off PH, when heated to 185° in CO., and ordinary P at 850°; decomposed by dilute alkali solutions to PH, H, H, KPO., and HK.PO.; combines with NH, to form a brown very unstable substance.

Phosphorus, cyanide of, v. Cyanogen phosphide, vol. ii. p. 358.

Phosphorus, fluorides of. Two fluorides of P are known, PF, and PF,; these formulæ are molecular. The compounds are gases at ordinary temperatures.

PHOSPHORUS TRIFLUORIDE PF. (Phosphorous fluoride.) Mol. w. 87-96. V.D. 43-7 (Moissan, A. Ch. [6] 6, 433).

Formation.—1. By the reaction of PbF₂ with Cu phosphide (M., l.c.).—2. By adding AsF₃ to PF₂ (M., l.c.).—3. By the reaction of PbF₂ with PCl₃ or POCl₃ (Güntz, C. R. 103, 58).—4. By adding PBr₃ to genly heated ZnF₂ (M., A. Cl₃ [6] 19, 286).

Preparation.—1. AsF₃ is dropped into perfectly dry PCl₂; the gas is shaken with a little water, and dried over H₂SO₄ (M_{*}, C. R. 100, 272).

2. A mixture of well-dried Cu₂P₂ and PbF₂ free from SiO₂ is heated in a brass tube to dull redness, the gas is passed by a leaden tube through two very small bottles (2 or 3 c.c. capacity) containing H₂SO₄, then through pumice soaked in H₂SO₄, and is then collected over Hg.—3. PBF₃ is gradually added to warm ZnF₂, the gas is washed by passing through water, then dried by passing over pumice soaked in H₂SO₄, and collected over Hg (M. A. Ch. [6] 19, 286).

Properties.—A colourless gas, condensed to a colourless liquid at -10° and 40 atmos. pressure. The gas is not liquefied at 24° under a pressure of 180 atmos., but liquefaction occurs when the pressure is suddenly reduced to 50 atmos. (Moissan, l.c.). PF, does not fume in the air; it is very slowly decomposed by water, with formation of H₂PO₂Aq and HFAq; burns when mixed with 0; decomposed by heat; also by electric sparks.

Reactions and Combinations .- 1. Decomposed by heat; in a glass apparatus P and SiF, are formed; in contact with Pt black a gas is formed, probably containing F (Moissan, C. R. 102, 763).—2. Electric sparks slowly decompose PF₃, forming PF₃ and P (Moissan, C. R. 102, 763).—3. Burns when mixed with pure oxygen and ignited; a mixture of 1 vol. PF, and 1 vol. O explodes violently when sparked, with formation of POF, (M., C. R. 102, 1245).-4. Very slowly decomposed by water, with formation of H3PO,Aq and HFAq; more rapidly decomposed by steam at 100°.-5. According to Berthelot (A. Ch. [6] 6, 358) potash solution produces a fluophosphorous acid probably analogous to fluoboric or fluosilicic acid; Moissan (C. R., 99, 655) says that a fluoride and a phosphite are formed.-6. Absorbed rapidly by bromine with formation of PBr₂F₃ (v. Phosphorus bromoriuoride, p. 181), also by chlorine, with formation of PCl₂F₃ (v. Phosphorus chlorofluoride, p. 133).—7. Decomposed rapidly by solutions of chromic acid or potassium permanganate.-8. Decomposed by hot sodium, copper, boron, and silicon (M., C. R. 99, 655).—9. Combines with ammonia to form white, flocculent compound, which is decomposed

by water (M., I.c.).—10. Combines with fluorine to form PF, (Moissan, Bl. [8] 5, 454).

Determination of composition. — The compound was analysed by Moissan (C. R. 100, 272) by heating a known volume in a glass vessel, measuring the volume of SiF, formed, dissolving the P deposited in HNO Aq, and estimating as Mg-NH, phosphate.

PHOSPHORUS PENTAFLUORIDE PF, (Phosphoric fluoride). Mol. w. 125'96. V.D. 68'2 to 65'1 (Thorpe, A. 182, 201; Moissan, C. R. 102, 763;

103, 1257).

Formation .- 1. By passing PF, into Br at -15°, PBr.F., is formed, and when heated this gives PF, and PBr. (Moissan, C. R. 101, 1490).

2. By the reaction of AsF, with PCl., -3. By direct combination of PF, with F (M., Bl. [3] 5, 454).

Preparation. - AsF, is added gradually to PCl. surrounded by a freezing mixture; the gas which comes off is passed through PCl, contained in a tube which is kept cold, and is collected over

Hg (Thorpe, A. 182, 201).

Properties and Reactions. — A colourless, strongly-smelling gas, which fumes in air and rapidly attacks the membranes of the mouth and the bronchial tubes. Condensed at 15° and 46 atmos. to colourless liquid which does not act on glass (Moissan, C. R. 101, 1490); on partially releasing pressure the liquid solidifies, but soon again becomes liquid (M., I.c.). Decomposed by powerful electric sparks (150 200 mm. long) to PF, and F (M., C. R. 103, 1257), but not by ordinary sparking (Thorpe, l.c.). Incombustible and does not support combustion. Not acted on by heating with phosphorus to dull redness, nor with sulphur vapour at 440°, nor iodine at 500° (M., l.c.). In presence of trace of water acts on glass, forming SiF, and POF, Passed over gently heated spongy platinum is partially de-composed to PF, and F; when the Pt is heated to dull redness a compound of Pt with P and F, probably PF_s.PtF₂, is formed (M., Bl. [3] 5, 454). Phosphorus, fluobromide of; v. Phosphorus

BROMOFLUORIDE, p. 131 Phosphorus, fluochloride of; v. Phosphorus

CHLOROFLUORIDE, p. 133.

Phosphorus, haloid compounds of. P combines readily with the halogens, with production of much heat, to form compounds PX, and PX,; besides these, the compound PL is also known. Several compounds of the type PX, and at least one of the type PX, (viz. PF,), have been gasified, so that the formulæ are molecular. The haloid compounds of P are decomposed by water, the fluorides only very slowly, with formation of oxyacids of P and halogen acids; these compounds also combine with many other haloid compounds, both of metals and non-metals, to form double salts.

Phosphorus, hydrides of. P and H do not resplaces, hydraes of. P and H do not combine directly; but hydrides of P are produced by evolving H in contact with phosphites or hypophosphites. Three hydrides of P have been isolated; PH., PH. (or P.H.), and P.H (or P.H.). Janssen (Repert. Chim. app. 8, 393) obtained a crystalline, explosive substance by the reaction of milk of lime with P, to which he care the formula PH. gave the formula P.H. At the ordinary temperature and pressure the first hydride is gaseous, the second siquid, and the third solid. The formula PH is molecular; Croullebois (C. R. 78, 496)

said that the V.D. of the liquid compound shows the mol. w. to be P.H., but no details are given; the mol. w. of the solid compound is unknown. The liquid hydride takes fire in contact with air; the gas inflames in air at c. 150°, and the solid at c. 200°; the processes for preparing gaseous PH, generally also produce more or less liquid P.H., the resultant gas is therefore spontaneously inflammable. PH, resembles NH, in its reactions, but it is much less decidedly alkaline; phosphonium compounds, c.g. PH,I, similar to ammonium compounds, are known

PH. PHOSPHORUS TRIHYDRIDE phoretted hydrogen. Phosphine). Mol. w. 88.96. Liquefies - 90°; solidifies -133.5°; melts at 2-132-15°; boils c. -85° (Olszowski, M. 7, 371). S.G. (air = 1) 1-185. V.D. 17°2. H.F. [P,H'] = 36, 600 (Ogier, C. R. 87, 210). S. 112 (Dy-

browski, J. 1866, 735).

Formation. - The gas obtained by the following methods is never pure PH_1 ; it contains more or less P_2H_1 , and generally also H; it is usually spontaneously inflammable. 1. By evolving H in contact with phosphites or hypophosphites in solution; phosphates are not reduced (Gm.-K. i. 2, 138; Fresenius, Fr. 6, 203; Herapath, Ph. 7, 57). P and H do not combine directly (Fourcroy a. Vauquelin, A. Ch. 21, 202; Dusart, C. R. 43, 1126).—2. By heating solutions of phosphites or hypophosphites (Gm.-K., l.c.). 3. By the action of boiling alkali solutions on P (H. Rose, P. 6, 199; 8, 191; 14, 188; 24, 109, 295; 32, 467; 46, 633).—4. By heating P with syrupy H₃PO,Aq, or with HClAq, HBrAq, or HIAq (Oppenheim, Bl. [2] 1,163).—5. By heating P with water to 200° (Oppenheim, l.c.).— 6. By long-continued heating P with blood to 35°-41° (Dybrowski, J. 1866. 735).-7. By the action of the electric current on moist molten P (Groves, C. J. 16, 268).—8. By heating P with H₂O to c. 200°.—9. By decomposing Zn phosphide by dilute acids, or boiling alkali solution Schwarz, D. P. J. 191, 396). According to Lüpke $(C.\ C.\ 1890.\ {
m ii}.\ 642)$, the gas obtained by acting on phosphide of Mg, Sn, or Zn with dilute acid is not spontaneously inflammable. - 10. By treating Cu phosphide with KCN and a little 80 p.c. alcohol (Gm.-K. i. 2, 138).—11. By decomposing phosphides of the alkali or alkaline earth metals by water or dilute acids.

Preparation .- 1. A small flask carrying an exit tube is nearly filled with a conc. solution of KOH in 80 p.c. alcohol; small pieces of P are dropped in, and the flask is heated; the gas is passed through a CaCl, tube to absorb alcohol vapour, and collected over water. The gas thus prepared does not contain more than c. 45 p.c. PH. (Hofmann, B. 4, 200); it is generally free from the spontaneously inflammable hydride. The gas prepared by the action of KOHAq on P contains some P2H, and much H; it is spontaneously inflammable in air. The simplest way of preparing this gas is to place a few small pieces of P in a little flask which carries a cork with two tubes, one fitted with a stopcock and passing just through the cork, and the other bent like an ordinary gas-delivery tube and dipping under water in a basin; the flask is nearly filled with conc. KOHAq; the tube with the stopcock is attached to the gas-supply, the cork is fitted loosely into the flask, and a stream of coal gas is passed

through the apparatus for a few minutes, after which the cork is fitted tightly into the flask, the estopcock is closed, and the flask is heated. During this process the end of the delivery-tube is kent under the surface of the water in the basin. After a few minutes gas is evolved, and each bubble takes fire as it comes into contact with the air after passing upwards through the water in the basin. If the whole of the air is not driven out of the apparatus before the flask is heated, serious explosions may occur.—2. The best way of preparing pure PH, is to decompose PH,I by KOHAq. A small flask is fitted with a caoutchouc cork, which carries a tube furnished with a bulb and stopcock and an exit-tube; pieces of PH,I about the size of peas are placed in the flask along with several small pieces of glassrod, KOHAq (c. 1 pt. KOH in 2 pts. H2O) is allowed to drop from the bulb-tube very slowly on to the PH I in the flask. Pure PH, is evolved without heating; if the KOHAq is added too rapidly the gas may contain a little P.H. and be spontaneously inflammable (Hofmann, B. 4, 200; Rammelsberg, B. 6, 88). About 1 litre PH₃ is obtained from 7-7½ g. PH₄I (for preparation of PH,I v. Phosphonium compounds, p. 123).

Properties .- PH, is a colourless gas, with a very disagreeable smell like that of onions mixed with decaying fish; very poisonous; slightly soluble in water (v. beginning of this article). The solution glows in the dark, and deposits amorphous P when exposed to light and air; on boiling, PH, is given off. PH, is slightly soluble in alcohol, ether, ethereal oils, and blood; it is completely absorbed by solution of bleaching powder, also by Cu,Cl, in HClAq (v. Combinations, No. 4). PH, combines with the halogen acids to form salts similar to those of NH₄ (v. Phosphonium compounds, p. 123); the H of PH₃ is replaceable by organic radicles (v. Phosphines, p. 116). PH, reduces solutions of salts of heavy metals. PH, free from P,H, takes fire in air at The gas prepared as mentioned under Formation takes fire immediately on contact with air; it loses this spontaneous inflammability by exposure to sunlight, by passage through a U-tube cooled to -10° , by mixing with small quantities of Al_2O_3 , wood charcoal, various gases, &c. (v. Graham, P. M. 5, 401). These processes remove P,H, to the presence of which the ready inflammability of the gas is due. Addition to PH, of 1 of its weight of P,H, causes the gas to become inflammable in air; the presence of $\frac{1}{1000}$ to 1 or NO produces the same effect (Graham, l.c.; cf. Landolt, A. 116, 193). The gas prepared by the action of KOHAq on PH.I (v. Preparation, No. 2) is described by Hofmann as taking fire when gently warmed, and being sometimes inflamed by the friction of the stopper of the bottle in which the gas may be kept. According to Rammelsberg (B. 6, 88), the gas prepared in this way is sometimes spontaneously inflammable. The gas prepared in this way takes fire when passed into conc. AgNO,Aq (Poleck a. Thümmel, B. 16, 2442).

Reactions.—1. PH, is decomposed by heat; when passed through a red-hot tube, lustrous, amorphous P is deposited (Merz a. Weith, B. 18, 718).—2. Decomposed by electric sparks to

P and H; the process takes place with regularity, 20 c.c. are decomposed in 5-6 mins, with production of P and 30 c.c. H (for description of an apparatus for lecture purposes v. Hofmann, B. 4, 204) .- 3. PH. burns in air at c. 150° with production of P2O, and H2O; if a cold substance is brought into the flame, yellow red specks of amorphous P are deposited .- 4. No reaction occurs when pure PH, free from P,H, is mixed with oxygen, but the mixture explodes if the pressure is suddenly lowered; explosion is said to occur after some hours at the ordinary pressure (Labillardière; v. Gm.-K. i. 2, 144).— 5. Bubbles of PH, burn explosively to PCl, and HCl if passed into a vessel filled with chlorine; if the Cl is diluted with CO, the action is slower, and some P separates.—6. Bromine and iodine react similarly to Cl; if PH, is heated gently with iodine, some PHI is formed .- 7. Heated with sulphur, H.S and P sulphide are formed (Jones, C. J. [2] 14, 148).—8. Salts of the alkali metals and of the alkaline earth metals decompose PH₃, producing phosphites and hypophosphites (Winkler, P. 111, 443).—9. Solutions of salts of heavy metals generally decompose PH, with production of metallic phosphides, which sometimes combine with the excess of the metallic salts (v. Kulisch, A. 231, 327). AgNO, Aq forms a yellow compound (? Ag, P.3AgNO,), and then black Ag, P which is quickly reduced to Ag (Poleck a. Thümmel, B. 16, 2442); HgCl, Aq, according to Ashan (Chem. Zeitung, 10, 82, 102), forms a yellow compound $3 Hg_1 P_2$.7HgCl₂, a red compound 4Hg₃P₂.5HgCl₂, and a brown compound Hg₃P₂.HgCl₂; PtCl₁ is said to form Pt.PH₂ (Gavazzi, B. 16, 2279); chlorides of Cr, Co, Cu, Au, Fe, and Ni are reduced, with formation of phosphides of the metals, or of metal and P. 10. Potassium permanganate solution is reduced by PH, to Mn₂O₃, K₂HPO₄ being also formed (Gavazzi, B. 16, 2279).—11. PH₂ is decomposed by many oxides, acids, and salts, e.g. by H.S, SO, NO, N₂O, PCl₃, HNO₃ (no reaction at -25°; Besson, C. R. 109, 644), H₂SO₄ (v. Besson, l.c.), SbCl₃, &c., also by certain metals, e.g. Sb, Cu, Fe, K, and Zn (v. Gm.-K. i. 2, 138).—12. With haloid compounds of arsenic PH, reacts to form haloid acid and phosphide of As (Besson, C. R. 110, 1258). -13. With an ethereal solution of bismuth bromids forms a black lustrous body, probably PBrH(BiBr₂)₂ (Cavazzi a. Tivoli, G. 21,

Combinations.—1. With the halogen acids to form compounds of the type PH,X (X = CI, Br, or I); combination with HI and HBr occurs at the ordinary temperature and pressure, with HCl combination occurs at -30° to -35° under the ordinary pressure, or at 14° under a pressure of 20 atmos. (Ogier, Bl. [2] 32, 483; v. also Skinner, Pr. 42, 283). At very low temperatures PH, seems to combine with H,SO, (v. Phosphonium sulphare, p. 124). "The compounds PH,X are described under Phosphonium compounds, p. 123.—2. When PH, is strongly compressed in presence of water, the gas liquefies and floats on the water. If the pressure is now suddenly released, a white crystalline solid is formed, but this decomposes again when the pressure is reduced below a certain amount (Cailletet a. Bordet, C. R. 95, 58; v. Phosphonium compounds, p. 123).—8. White compounds, assily

decomposed on removing pressure, are said to be formed by compressing PH, with carbon divide, and with carbon disulphide, in presence of water (C. a. B., l.c.).—4. A solution of cuprous chloride in HClAq absorbs PH, rapidly; a white crystalline mass of Cu.Cl., 2PH, is formed, but this liquefies as more PH, is passed in (? with formation of Cu.Cl., 4PH,); the crystals Cu.Cl., 2PH, are decomposed by warming, or by addition of water, to PH, HCl, and Cu.P; the liquid compound loses PH, in a stream of an indifferent gas, with production of the crystalline compound (v. Riban, Bl. [2] 35, 385). This behaviour of PH, towards Cu.Cl. gives a method for preparing pure PH, and also for estimating PH, in a mixture of gases.

PHOSPHORUS DIHYDRIDE PH, or P.H. (Liquid phosphoretted hydrogen). Mol. w. said to be 65-92, corresponding with V.D. c. 33, but no details given (Croullebois, C. R. 78, 496). Gattermann a. Hausknecht (B. 23, 1174) failed to determine V.D. as the compound always decomposed. A spontaneously inflammable gas containing P and H was obtained by Gengembre in 1783 (Crell's Ann. 1789. 450). The fact that this gas lost its inflammability by standing over air containing water was explained by Dumas (A. Ch. [2] 31, 113) by supposing that the gas was a mixture of two hydrides of P, one only of which was spontaneously inflammable; to one of these Dumas gave the formula PH, and to the other the formula PH₃. In 1832 H. Rose (P. 6, 199; 8, 191) thought that the two gases had the same composition, but were isomeric one with the other. After Graham (P. M. 5, 401) had examined the conditions under which spontaneous inflammability was removed from or bestowed on the gas, Le Verrier (A. Ch. [2] 60, 174) came to the conclusion that the gas consisted chiefly of PH, but that it contained also a very inflammable compound PH, which was decomposed by light into PH, and a solid hydride PH. In 1845 P. Thénard made a fuller study of the subject (A. Ch. [3] 14, 5); he showed that spontaneously inflammable phosphoretted hydrogen, when passed through a tube cooled to under 10°, deposited a liquid having the composition PH2, which liquid was extremely inflammable, and that this liquid decomposed in light into gaseous PH, and a solid to which he gave the formula P.H. In 1874 Croullebois said that the V.D. of the liquid hydride corresponds with the formula P₂H₄, but no details were given (C. R. 78, 496); in 1890 Gattermann a. Hausknecht attempted to determine V.D., but found that the compound decomposed (B. 23, 1174).

Preparation.—Impure Ca phosphide is prepared by heating dry CaO to bright redness in a crucible, and adding dried P little by little, the lid being replaced after each addition of P. The crucible should be arranged so that the P is brought under the strongly-heated CaO; this may be done by placing a few pieces of P in a crucible, filling up with dry CaO, covering tightly (but leaving one small hole), placing the crucible in a furnace arranged so that the lower part of the crucible projects downwards through the bottom of the furnace, heating the upper part of the erucible to bright redness, and then warming the lower part so as to vapourise the P. Small quantities are prepared by placing a dry piece of

P in the closed end of a tube of hard glass, partly filling the tube with dry CaO, arranged so that there is a little space between the CaO and the P, placing the tube in a combustion furnace, heating the CaO strongly, and then warming the P. The CaO is transformed into a mixture of Ca phosphide and phosphate; the phosphide is nearly black : the unchanged CaO is picked out when the action is over, and the phosphide is at once placed in a stoppered bottle. (For modifi-cation of process v. Gattermann a. Hausknecht, B. 23, f174.) A three-necked bottle of about 2 litres capacity is filled three-quarters with water: one of the necks carries the tube from a H apparatus, which tube dips considerably under the water, the middle neck carries a piece of tubing about 15 mm. internal diameter, dipping 2 or 3 cm. under the water, and the third neck carries an exit tube in communication with a condenser; between the condenser and the three-necked bothle is placed a test tube, to collect part of the water vapour coming over. The condenser consists of a tube about 100 mm. long and 30 mm. diameter, narrowed so that the lower end forms a tube about 40 mm. long by 12 mm. wide; this condenser is closed by a cork through which pass the entrance tube from the threenecked bottle and an exit tube, which is bent downwards and dips under the surface of water; these two tubes are cut off obliquely just below the cork. The condenser is placed in a deep vessel full of cold water which contains sufficient ice to keep the temperature at 0°. H is passed through the apparatus until all the air is driven out, the three-necked bottle is placed in a waterbath until the contents are warmed to 60°, and Ca phosphide, in pieces the size of peas, is dropped down the wide tube in portions about 2 g. at a time and at a rate such that 50 g. are added in 15 to 20 minutes. Gaseous P hydride passes off and bubbles up through the water, and the liquid hydride collects in the condenser, about 1-2 c.c. being obtained for 50 g. Ca phosphide used (Hofmann, B. 7, 531; Gattermann a. Hausknecht, B. 23, 1174; the many precautions to be taken in working with this compound are described by G. a. H.).

Properties and Reactions.—A colourless, highly refractive liquid; insol. in water; burns in air, with bright flame to P₂O, and H₂O; does not solidify at -10°; boils 57°-58° at 735 mm. (G. a. H., Lc.). S. G. 1-007 to 1-016 (G. a. H.). Decomposed by light into PH, and solid P₂H; the liquid may he kept for a short time in sealed tubes, but decomposition soon begins, and the tubes explode violently (G. a. H.). The same decomposition is effected by conc. HClAq, air mixed with CO₂, &c. Passage of the gas prepared as described above through a little conc. HClAq removes every trace of PH₂, and hence causes the gas which issues to be non-inflammable. If CO₂ is passed through the U-tube containing liquid PH₂ a nearly invisible greenish light appears at the end of the tube; this flame is not hot enough to ignite a candle (v. Hofmann, B. 7, 531; Thénard, A. Ch. [3] 14. 5; Bonet a. Bonfil, J. pr. 55, 247; Gattermann a. Hauskecht, B. 23, 1174). The composition of PH₂ was determined by Thénard by decomposing a known quantity by direct sunlight in a graduated tube filled with Hg: 100 parts liquid phos-

phide gave 61.8 parts gaseous PH, and 38.2 parts solid P₂H; -i.e. 1 molecule P₂H was produced for 8 mols. PH₃, hence the equation 5PH₄ = P₂H + 3PH₃. This equation was confirmed by G. a. H., who made also direct estimation of H by burning with PbCrO₄ in a current of CO₂ (B. 23, 1174).

DIPHOSPHORUS HYDRIDE P_2H or P_4H_2 . Mol. w. unknown. H. F. $[P^2,H] = 17,700$ (Ogier, C. R.

89, 707).

Formation.—1. By decomposing phosphide of Ca or K (Magnus, P. 17, 52) by HClAq.—2. By the action of light, HClAq, Cl (Le Verrier, A. Ch. [2] 60, 174), and various other reagents, on PH.—3. By the decomposition of PI₂ by water (Rüdorff, P. 128, 473). Hittorf (P. 126, 193) obtained only amorphous P by this process.

Preparation. — A two-necked bottle is arranged with an exit tube dipping under water, and a wide entrance tube, down which is passed the delivery tube of a H-apparatus; conce HClAq is placed in the bottle, H is passed through until all air is driven out the H apparatus is removed, and small pieces of freshly-prepared Ca phosphide (for preparation v. Preparation of phosphorus dihydride, p. 137) are dropped slowly into the bottle. The P₂H which forms in the bottle is rapidly washed with cold water, and dried in vacuo (P. Thénard, A. Ch. [3] 14, 5).

Properties.—A yellow flocculent powder, which comes orange-yellow in light; tasteless and odourless. When dry may be heated to c. 200° before taking fire; ignited by a blow of a hammer.

Reactions.—1. Ignited by heating in air to c. 200°; also by a blow of a hammer.—2. Slowly decomposed in moist air, especially it in sunlight, to P₂O₃ and H.—3. Distillation in hydrogen produces PH₃ (Thénard, l.c.).—4. Chlorine forms PCl₃ and HCl.—5. Dissolves in dilute nitric acid; oxidised with ignition by conc. HNO₂Aq.—6. Alcoholic solution of potash produces PH₃ and H; addition of water to the reddish solution ppts. yellow flocks of? amorphous P or a lower oxide of P.—7. Explodes when mixed with potassium chlorate, silver oxide, mercuric oxide, or cupric oxide, and struck or warmed.
S. Ppts. metallic phosphides from solutions of salts of many heavy metals (Le Verrier, l.c.).

Determination of composition.—The quantity of P in the solid hydride was determined by Thénard by heating with a weighed quantity of PbO, and weighing the mixture of PbO and Pb phosphate thus produced; the H was determined by decomposing by red-hot Cu, and collecting the H set free. Rüdorff decomposed the hydride by heat, and collected and analysed the mixture of PH, and H thus formed; he also oxidised the compound by HNO₂Aq, and estimated P as Pb phosphate.

Phosphorus, iodides of. P and I combine directly, even at -24°; two iodides, PI₂ and PI₃, have been isolated, and the existence of a third, PI₃, is probable.

PHOSPHERUS DI-TODIDE PI₂ or P₂I₄. Mol. w. not known. H.F. [P,I²] = 9,880 from solid P and I; 20,680 from solid P and gaseous I (Ogier, C. R. 92, 88).

C. R. 92, 88).

Formation.—1. By adding I to P Combination occurs even at -24°, with production of much heat, and ignition of the excess of P if air is admitted; amorphous P is produced be-

sides PI, (v. Wurts, A. Ch. [8] 42, 129).—2. By the reaction of I with PH; also of I in acetic acid on PCl, (Hofmann, A. 103, 805; Ritter, A. 95, 210).

Preparation.—One part by weight of P is dissolved in CS, and St parts of I are added little by little. When the colour of the dark brownish-red liquid thus produced has changed to orange it is cooled to 0° for some hours, when the vessel becomes filled with crystals; the crystals are freed from CS, by heating in a water-bath, while a stream of dry air is passed over them (Coreawinder, A. Ch. [3] 30, 242). The crystals may also be obtained by evaporating the solution in CS, in a stream of CO, (Borthelot a. Luca, C. R. 39, 748). Corenwinder says that from 2 to 3 g. P, and 60 to 75 c.c. CS, are convenient quantities to use.

Properties and Reactions.—Large orange-coloused prisms, melting at 110° (Gorenwinder, l.c.). Heated in O gives P₂O, and I (Berthelot, C. R. 86, 628, 787, 859, 920; 87, 875, 667). Decomposed by H₂O to H₂PO₃Aq, PH₃, HIAq, and a yellow flocculent solid supposed to be amorphous P (Hittorf, P. 126, 193), regarded by Rüdorff as solid P₂H₂ (P. 128, 473), and said by Gautier (C. R. 76, 49, 173) to be P₃H₃O.

Phosphorus Tri-iodde PI, (Phosphorous iodiale). Mol. w. 410-55. H.F. [P,I] = 10,900 (Ogier, C. R. 92, 83). This compound is obtained in large red prisms by dissolving one part of P in CS₂, adding a solution of 12½ parts of I in CS₂, concentrating much out of contact with air, and then placing in a freezing mixture. As the crystals are very sql. CS₂, they should be at once freed from mother-liquor, and dried in a stream of dry air at c. 50°. The crystals melt at 55°, and boil at a higher temperature, with evolution of I. PI₂ is very deliquescent; moist air decompeses it at once to H,PO,Aq and HIAq (Conenwinder, A. Ch. [3] 30, 242).

Phosphorus Perta-todde PI₄ (Phosphoric

PHOSPHORUS PENTA-IODIDE PI₈ (Phosphoric todide). Isolation doubtful. Hampton (C. N. 42, 180) obtained a dark-crimson, very deliquescent solid, giving numbers on analysis agreeing with 80 p.c. PI₈ + 20 p.c. PI₈, by dissolving P in a little CS₂ in a stream of pure dry N, adding rather more than enough I to form PI₈, distilling off CS₂ (in a N stream) at 45° under reduced pressure, and then warming to 50°; at 55°, under the reduced pressure, I began to sublime.

Phesphorus, iodo-chloride of, PLCl. Produced by adding much I to a little PCl. allowing to stand in moist air for some days, drying the crystals in a stream of air, dissolving in CS, and crystallising: large, red, six-sided crystals, very hygroscopic; decomposed by water to H.PO.Aq, HClAq, and HIAq (Moot, B. 13, 2029).

Phosphorus, nitride of. No compound of Pand N has been isolated with certainty. A substance supposed to be a flitride by Rose (P. 24, 303; 28, 529) and Wohler a. Liebig (A. 11, 139) was found to contain H. Briegleb a. Geuther (A. 123, 236) think that a compound P.N. is perhaps produced by the reaction of PCl, on hot Mg,N, in an atmosphere of N. Phosphorus, oxides of. P and O combine

Phosphorus, oxides of. P and O combine very readily, with production of much heat; four compounds are produced according to the conditions: P.O. P.O. P.O. and P.O.; the V.D.

of the second of these shows that its mol. formula as a gas is P₄O₅. The oxides P₂O₅ and P₂O₅ are anhydrides; the former reacts with water to produce the acid H.PO,, and the latter to produce three acids, HPO, H,PO, and H₄P₂O₇; the oxide P₂O₄ is not the anhydride of a corresponding acid—with water it produces the two acids H₂PO₄ and H₂PO₄.

The only oxide formed when P glows in air at ordinary temperature is P₁O₃, but P₂O₄ is formed by drawing air over P without the latter glowing (Thorpe a. Tutton, C. J. 57, 573); at 50°-50° small quantities of P₂O₄ are produced, and this oxide is produced in larger quantities when the P is actually ignited; at moderately high temperatures and with a limited supply of air the oxide P.O is formed in addition to P.O. and P2O2. If the products of the slow burning of P in dry air are heated together in CO2, the oxide P2O4 is formed, along with some P4O. The products of burning P in a limited supply of dry air generally contain small quantities of P; this may be removed by sucking the products through a tube heated by steam (Thorpe a. Tutton, C. J. 49, 833).

PHOSPHORUS SUBOXIDE P.O. Mol. w. uncertain. Some doubt still remains concerning the composition of the lowest oxide of P; but the evidence is in favour of the existence of a definite oxide P.O. Le Verrier (A. 27, 167) obtained a yellowish solid by exposing P in PCl, or in ether to air, warming the solid thus formed with water, and drying over H2SO. A similar product was obtained by the incomplete combustion of P in air, or by the action on P of such oxidisers as iodic or periodic acid in presence of water (v. Gm.-K. i. 2, 107). This substance was generally looked on as an oxide of P; Le Verrier gave it the formula P₄O; Schrötter (W. A. B. 8, 246) thought it was only a mixture of ordinary and amorphous P. Reinitzer a. Goldschmidt (B. 13, 845) obtained the oxide P₄O by heating POCl, with P to 200°-250°, also by heating POCl, with Zn, Mg, or Al, at 100°. Thorpe a. Tutton (C. J. 49, 833) found that P₄O is one of the products of burning P in a limited supply of air at moderately high temperatures, and that it is formed when the products of the slow burning of P in dry air are heated to c. 300° in CO... The experiments of R. a. G. indicate the existence of two varieties of P₄O; one of these reacts with hot alkali solutions, evolving PH,, and reduces salts of Au and Ag and mercurous salts, and the other is not acted on by alkalis, and does not reduce salts of Au, Ag, or Hg.

Preparation and Properties of P.O which reduces salts of Ag, Au, and Hg.—1. Thin plates of pure Zn are heated with POCl, in a sealed tube in a water-bath at 100° for some hours, the liquid, with suspended solid matter, is poured off, the solid is allowed to settle and the liquid is decanted off; the solid is heated as before for some time with POCl, (to remove any Zn present), the liquid is poured off, the solid is washed with CHCl, to remove POCl, then with HClAq and finally with water; the solid is then dried for some days in vacuo (Reinitzer a. Goldschmidt, B. 13, 849); the other products of the reaction are ZnCl, and Zn2PO. As thus prepared P₄O is an ofenge-red powder. It very obstinately refains water, the sample made by R. a. G. con-

tained c. 8 p.c. water, but the P and O were in the ratio P₄O. This oxide in moist air evolves PH.; it reacts with boiling alkali solutions forming PH, and alkali phosphite and phosphate; solutions of salts of Au and Ag, and mercurous salts, are reduced with ppn. of the metals; heated in H, P is given off, and P₂O₅ remains.—2. PCl₃ is placed in an open flask, of c. 1 litre capacity, containing a layer about 2 cm. thick of P in small pieces; the PCl_a just covers the P; after c. 2 days the PCl_a is poured off, the pieces of P and the adhering yellow film are loosened from the flask, and allowed to fall slowly into cold water (if water is added in quantity, heat is produced, and the products of the slow oxidation of P are decomposed). After a little, the water is filtered from suspended P. and the clear yellow filtrate is heated to 80°, when a very finely divided yellow solid settles down; this solid is washed with warm water in a filter removed from the filter while moist, and placed in a basin, over H.SO, in vacuo. Le Verrier's P.O was tasteless and odourless, did not change in dry air or O, but in moist air it gave off PH,; it was decomposed somewhat above 360°, giving off P and leaving P,O,; oxidised by Cl to PCl, and P₂O₃; heated with conc. H₂SO₄, gave SO₂; unacted on by HClAq; oxih₂O₄, gave SO₅; unacted on by HNO₄Aq; exploded wifh KClO₅; readily combined with H₂O-to form P₄O.H₂O. The oxide obtained by Thorpe a. Tutton (C. J. 49, 833) was formed by slowly burning P in dry air, transferring the products to a tube filled with CO₂, exhausting by a Sprengel pump, and heating to 290°; as the oxide is described as orange-red, it was probably the form of P.O which reduces salts of Au. Ag.

Preparation and Properties of P.O which does not reduce salts of Ag. Au, and Hg.—POCl, is heated with an excess of P in a sealed tube to 200°-250°; the sides of the tube become covered with a scarlet-coloured solid, which is washed with CS₂ (to remove P) and dried in vacuo (R. a. C., Lc.; the other products are PCl₃, P₂O₃Cl₄ and a little P₂O₃). As thus prepared, P₁O is a scarlet-red solid; S.C. 1-88; it is not constant to the colour scarled in solutions and its constant and it acted on by water or alkali solutions, and it does not reduce salts of Ag, Au, or Hg. This form of P₄O seems to have been obtained by Pelouze (A. 3, 52) by burning P in O; and by Le Verrier (A. 27, 175) by burning P in a thin layer on a porcelain plate, washing with water to remove oxyacids, and boiling with PCl, to remove P.

PHOSPHOROUS OXIDE P.O. (Phosphorus trioxide. Phosphorous anhydride.) Mol. w. 2196; same in solution in C.H. (Thorpe a. Tutton, C. J. 57, 545). Melts at 22.5°; boils at 178.1° (T. a. T.). S.G. $\frac{21^0}{6^0}$ liquid P₄O₆ 1-9431; solid P₄O₆ at $\frac{21^0}{6^0}$ c. 2-135. S.G. at b.p. = 1-6897 (T. a. T.). V.D. 111-9. S.V. 130-2 (T. a. T.). $\mu_{A} = 1.5311$; $\frac{\text{Mol. w.} \times \mu}{\text{S.G.}} = 60.5$ (T. a. T.). Mol. w. $\frac{\mu_H - \mu_A}{8.G.} = 4.17$. M.M. 9.962.

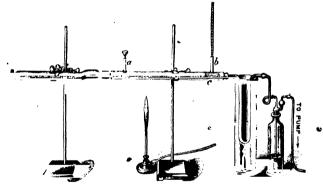

Preparation.—A piece of combustion-tubing about 40 mm. bore is drawn into the shape shown in the figure on following page, and is fitted by a

good cork into a brass tube, which is surrounded by a wider tube of brass; water is introduced at a between the brass tubes, and a thermometer is placed at b. A loose-plug of glass-wool is placed in the inner brass tube at c. The U-shaped condenser is of rather narrow bore, the limbs are about 800 mm. long, a small bottle is attached to the vertical piece at the bottom of the condenser, which is itself connected with the inner brass tube by a good cork; the condenser and small bottle are surrounded by ice and salt. The bottle between the condenser and the pump contains oil of vitriol. Two sticks of P are dried between filter-paper, cut into pieces c. 25 mm. long, and placed in the combustion tube, which is then narrowed at the open end and fitted into the brass tube; the pump is set in action, and the P is ignited by holding a small flame beneath the open end of the combustion-tube. Air is sucked over the P as rapidly as possible; if the combustion is too local, much P.O. is formed; considerable quantities of red P.O are formed near the burning P. When the P has burnt for c. 15 mins. the water in the brass tube is heated to c. 50°, at which temperature it is kept till near

132°. Mol. w. as gas, and also in solution in C.H. (determined by cryoscopic method), corresponds with P_sO_s . Soluble without change in O_sH_s , CS_s , $CHCl_s$, and ether. Heated to c. 200° in sealed tube begins to decompose to P_sO_s and P. Decomposed by light, with separation of red P. T. a. T. (C. J. 59, 1019) several times obtained clear, transparent, perfectly-formed crystals of P4O8 by slow spontaneous sublimation in vacuo, which remained unchanged for many days, although exposed to light. Spec. volume at b.p. = 130.2. (For details of thermal expansion and S.G. at B.p. v. T. a. T., C. J. 57, 545.) Reacts slowly with cold water, forming H_3PO_3Aq; with boiling water reaction is violent, PH, is evolved, and red P, or perhaps P,O, and H,PO,Aq are formed. Oxidises to P2O, by exposure to air or O: if temperature is raised the P.O. ignites and may explode. P.O. has a well marked physiological action; the action of P may be due to P.O., formed by the air oxidising the P (T.a. T., l.c. p. 573).

Reactions.—1. Heat decomposes P.O., form-

ing P2O4 and P (? P4O); the action begins at c. 210° in a sealed tube, and the whole of the P.O.

the end of the experiment, when it is raised to 60°. P.O. begins to collect in the condenser about 80 mins. after starting the combustion; if the glass-wool is packed properly (it should not be too tight) no P₂O₂ passes into the condenser, and if the temperature of the water does not exceed 60° only very small quantities of P pass over. The process is stopped when c. 5ths of the P is burnt, else the P₄O₆ may be oxidised. The condenser is removed, the P₄O₆ is melted by the heat of the hand, and run down into the little bottle, from which it may be transferred to another bottle which has been filled with dry CO.; this bottle should have a very tightlyfitting stopper, and should be kept in the dark in an atmosphere of CO₂ (T. a. T., *l.c.*).

Properties.—A white snow-like solid, with an

alliaceous offour resembling that of P; when melted and cooled slowly crystallises in long thin prisms, probably monoclinic; melts at 22.5° to a clear, colourless, very mobile liquid, which solidifies again at 21°; the liquid may be cooled in a narrow tube several degrees below m.p. without solidifying; boils at 178:1° in CO, or N.

is decomposed at 440° (T. a. T., p. 552). -2. Rapidly acted on by light, becoming yellow and then dark-red (T. a. T., p. 553). The action of light separates red P; the amount obtained after several months' exposure does not exceed 1 p.c. (T. a. T., C. J. 59, 1019). By exposing P.O. to light for some months in a sealed tube filled with dry CO2, then melting, filtering through glass-wool, and repeating this process several times, T. a. T. eventually obtained P4Os which remained perfectly clear and colourless after twelve months' exposure (l.c., p. 1023).-3. Oxidises to P.O. in air or oxygen; when quite free from P, the oxide is not spontaneously inflammable. Under reduced pressure in O the P.O. glows; on raising temperature to c. 70° at ordinary pressure the glow gives place to flame. Combination occurs between vapour of P4O6 and O; ozone is not formed. When P₄O₆ is thrown into O heated to 50°-60° ignition occurs with an intensely brilliant flame (T. a. T., C. J. 57, 569).—4. Glows continuously, and oxidises to P₂O₃, when a stream of ozonised oxygen is passed over it .- 5. Ignites in chlorine, burning with a Can be gasified in Hofmann's V.D. apparatus at greenish flame; when surrounded by ice and

exposed to slow stream of Cl a liquid is formed, which on distillation gives POCl, while PO.Cl (?) remains (T. s. T., C. J. 57, 572).—6. Reacts vio-lently with liquid bromine; using Br vapour at ordinary temperature, T. s. T. (C. J. 59, 1020) obtained PBr, and P₂O₃, and on then heating POBr, and PO₂Br (?) were formed.—7. Iodine reacts slowly; by heating with I and CS₂ under pressure, P₂O₂ and P₂I₄ are produced (T. a. T., *l.c.*, p. 1021). 8. Heated with sulphur, in CO₂ or N, two layers of liquid are formed; at 160° there is violent reaction, and solid P.O.S. is produced (v. Phos-PHORUS, SULPHOXIDE OF, p. 140; T. a. T., l.c., p. 1022) .- 9. Seems to form a Se compound analogous to P,O_aS, by heating with selenion (T. a. T., l.c., p. 1026).—10. Dissolves very slowly in water, forming H_1PO_1Aq (T. a. T., C. J. 57, 567); $P_4O_4 + 6H_2O + Aq = 4H_1PO_1Aq$. The action of hot water is very energetic; red P, or red P,O, is ppd., inflammable hydride of P is evolved, and H₃PO,Aq is formed; if the quantity of P₄O₆ exceeds 2 g. the action of hot water is violently explosive .-- 11. Dry hydrogen chloride is rapidly absorbed; PCl, is formed along with H.PO., H.PO., and yellow P (T. a. T., C. J. 59, 1022). - 12. Conc. sulphuric acid reacts violently, forming H₃PO, and SO₂; if 1 g. or more P4O6 is used, the mass ignites (T. a. T., l.c. p. 1026).—13. P.O. is rapidly oxidised to P.O. by sulphur trioxide, which is reduced to SO.; no compound could be obtained (T. a. T., l.c. p. 1026). According to Adie (C. J. 59, 230), if a little water is present, P₁O₂ and SO₃ form an unstable compound H₂PO₄.3SO₃.—14. Nitrogen tetroxide seems to react like SO₃, forming P₂O₅ and N2O3 or NO (T. a. T., l.c. p. 1028).-15. Phosphorus pentachloride produces PCI, and POCI,; phosphorus trichloride reacts at c. 180° in a sealed tube, forming a mixture of P₂O₃, PCl₃, and red P (T. a. T., l.c. p. 1028).—16. Sulphur chloride reacts violently, producing POCl₃, PSCl₃, SO₂, and S (T. a. T., l.c. p. 1026).—17. Ammonia reacts with some violence, probably producing OH.P.(NH₂)₂(v.Phosphamides, p. 105).—18. Cold dilute caustic soda, or caustic potash solution, slowly dissolves P₄O₄, forming a solution of Na or K phosphite; cold conc. or hot dilute solution. tion of soda or potash produces red P (or P.O?) and alkali phosphate, and evolves inflammable hydride of P.-19. Ignites in contact with absolute alcohol; by allowing the alcohol to drop slowly on to cooled P₄O₂ the acid P(OE1)₂OH is formed (T. a. T., C. J. 57, 559). P₄O₂ seems not to react with H₁ PH₂, CO₂ CO₂, SO₂ N, NO, CN, or C₂H₄ (T. a. T., C. J. 59, 1029).

PHOSPHORUS TETROXIDE P.O. (Phosphoroso-phosphoric oxide. Hypophosphoric oxide). Mol. w. not determined; corresponding sulphide has mol. w. P.S. Hautefeuille a. Perrey (C. R. 99, 33) noticed that a crystalline sublimate is obtained by heating the products of the combus-tion of P; Thorpe a. Tutton (C. J. 49, 833) proved that this sublimate is a definite oxide P₂O₄. Concerning the combustion of P in air v. pp. 128 and 139.

Preparation .- P is burnt slowly in a stream of air dried by H₂SO₄ and P₂O₅; the products are collected in a glass tube, surrounded by an outer tube filled with steam, and are then quickly transferred to a tube filled with dry CO,, the tube is drawn out, exhausted by a Sprengel pump

(care being taken to prevent entrance of moisture), and sealed; at c. 290° the white mass becomes orange-coloured, and then red, and a white crystalline sublimate of P₂O₄ is formed, white erystaine subministe of $r_2 o_4$ is formed, leaving $P_1 O_2$ and $P_4 O$ in the lower part of the tube. T. a. T. (p. 838) think that the $P_1 O_1$ is derived from the $P_2 O_2$, thus $7P_2 O_2 = 5P_2 O_4 + P_4 O_5$; that $P_1 O_4$ is formed by heating $P_2 O_4$ out of contact that $P_1 O_4$ is formed by heating $P_2 O_4$ out of contact that $P_1 O_4$ is formed by heating $P_2 O_4$ out of contact that $P_2 O_4$ is formed by heating $P_3 O_4$ out of contact $P_3 O_4$ is $P_4 O_4$ in $P_4 O_4$ in $P_4 O_4$ in $P_4 O_4$ in $P_4 O_4$ is $P_4 O_4$ in P_4 tact with O is shown by T. a. T. (C. J. 57, 552).

Properties and Reactions.—Colourless crystals, prebably orthorhombic; do not melt at 100°. Volatilises at c. 180°. Very deliquescent, forming H,PO,Aq and H,PO,Aq; from this reaction T. a. T. conclude that P.O. is not the anhydride of H.P.O., as an aqueous solution of this acid does not behave like a mixture of H₂PO₂ and H₂PO₃, and can be boiled without change. Solution of P₂O₄ in water reduces AgNO₃Aq to Ag, and HgCl₂Aq to HgCl; KMnO₄Aq is very slowly decolourised; 'magnesia mixture' gives an immediate ep., and after standing some time the filtrate gives a large pp., with NII, molybdate after heating with HNO.Aq.

PHOSPHORIC OXIDE P.O. (Phosphoric an-PHOSPHORIC OXIDE P.O. [Phosphoric an-hydride. Phosphorus pentoxide]. Formula probably molecular, from analogy of P.S., S.G. 2:387 (Brisson, Peaanteur specifique des Corps [Paris, 1787]). H.F. [P.O.] = 369,900; [P-O.,Aq] = 55,600 (Th. 2, 409). Formation.—1. This oxide is formed by burn-

ing P in a large excess of air; concerning the combustion of P in air v. pp. 128 and 189 .-2. It is also formed by burning P in such gaseous O compounds as NO, NO, ClO2. - 8. By distilling

P20,Cl.

Preparation.—A large glass balloon with a wide opening and two side necks is thoroughly dried; through a cork in the wide opening passes a piece of wide tubing, which reaches to about the centre of the balloon, and from the lower end of this tube a small porcelain basin is suspended by Pt wires; one of the side necks is connected with U-tubes containing pumice soaked in H2SO4, and the other side neck is connected with a wide-mouthed perfectly dry bottle, which is again in connection with a water-pump, a bottle with H2SO, being placed between the pump and the wide-mouthed bottle. A small piece of well-dried P is placed in the little basin, and is ignited by passing a hot wire down the glass tube, the mouth of which is then closed by a good cork; a rapid stream of air is sucked through the apparatus; the P is burnt to P.O., part of which collects on the bottom of the balloon and part passes into the bottle attached to the side neck. When the P is burnt another small piece is dropped down the glass tube into the little basin, and the process is continued. When sufficient P₂O₅ has collected in the bottle this is closed by a well-fitting stopper (Delalande, v. Marchand, J. pr. 16, 373; Mohr, Gm.-K. i. 2, 120. Grabowski (A. 136, 119) has described a vessel of timplate for preparing large quantities

Shenstone says that P₂O₃, prepared by the ordinary process, has generally reducing powers, and is not, therefore, trustworthy as a drying agent. S. recommends to heat for some days at c. 800° in a very slow stream of dry O; then to

heat at 800° in a more liberal, but still limited, supply of dry O until the reddish colour produced by the first heating has disappeared; then to heat at 800° in a more rapid stream of dry O so long as sublimation occurs; and finally to sublime, fractionally, in a current of dry O, from retorts of hard glass into receivers of the same material. The first portions of the sublimate should be rejected. The whole of these processes may be done in glass vessels. The retorts used in the final sublimation may be heated in a combustion furnace (private communication).

Hautefeuille a. Perrey (C. R. 99, 33) say that P.O. can be obtained in three forms : crystalline, amorphous and powdery, and glass-like. They say that when P is burnt in a glass tube in dry air, the crystalline form of P2O, is deposited on the colder part of the tube, the amorphous powdery form on the hotter part, and the vitreous form on that part of the tube which is heated to redness. These authors assert that crystalline P.O. is obtained free from the other forms by distilling the products of the burning of P; that heating the crystals in vapour of S produces the powdery amorphous form; that the vitreous variety is formed by heating either of the others to low redness; and that this vitreous form yields crystalline P.O. when sublimed at a red heat. Considering the facts brought to light by the work of Thorpe a. Tutton on the combustion of P (C. J. 49, 833; 57, 545; v. beginning of this article, p. 139), the existence of various modifications of P₂O₆ must be looked on as very doubtful. T. a. T. (C. J 49, 838) think it very likely that the crystalline form of P2O5 obtained by H. a. P. was P2O4; and it is probable that the differences in the properties of the powdery and vitreous P₂O₂ were due to admixture with P₂O₃. No analytical data are given by H. a. P. Shenstone (priv. comm.) says that P.O. purified by his method is crystalline, but becomes amorphous when suddenly heated.

Properties.—A snow-white, amorphous, inodorous, very deliquescent, solid. Melts and
sublimes below red heat (Lautermann, A. 113,
240); according to Davy (A. Ch. [2] 10, 218)
volatile only at white heat. Absorbs water very
rapidly; hence is used as a very efficacious drying
agent. P.O. is the anhydride of three phosphoric
acids: HPO, H.PO,, and H.P.O., Dry P.O. does
not change the colour of dry litmus paper.
Commercial P.O. often contains traces of P.,
which cause it to redden in light, and also traces
of As.O. derived from the impure P used; it
generally has more or less marked reducing
powers.

Reactions. — 1. Water produces HPO: H.P.O. is formed from HPO. by the long-continued action of moist air; and H.PO. is produced by continued heating of HPO.AQ.—2. P.O. removes H.O from many compounds which contain water or the elements of water; e.g. it produces anhydrides when heated with several acids, H.SO. gives SO., HNO. gives N.O., and hydrocarbons are often formed by heating P.O. with compounds of C. H. and O.—3. Heated with several metals, e.g. Fe, K. Na. Zn. metallic oxide, phosphide, and phosphate are formed.—4. Salis of acids the anhydrides of which are colatile are decomposed by heating with P.O., with formation of phosphates and volatilisation

boric acid.

Combinations. 1. With water (v. supra, Reactions, No. 1).—2. With sulphur trioxide to form P.O. 3SO, decomposed at 30° (Weber, B. 20, 80).—3. With silica and water to form P.O., SiO, 4H.O; formed by heating cone. H.PO, Aq with silica (Hautefeuille a. Margottet, C. R. 104, 156). Similar compounds with oxides of titanium, sirconium, and tin are described by H. a. M. (C. R. 102, 1017).

Phosphorus, oxyacids of. The three phosphoric acids are described in the article Phosphoric acids, p. 124, and the salts of those acids in the article Phosphares, p. 106; the other oxyacids of P and their salts are described under Phosphorus, oxyacids of, and their salts, p. 149

Phosphorus, exybromide of, POBr, (Phosphoryl tribromide). Mol. w. 286-2. Melts at 55° (Baudrimont, A. Ch. [4] 2, 58); at 45°-46° (Ritter, A. 95, 210). Boils at 195° (Ritter, Le.); at 193° (Gladstone, P. M. [3] 35, 345). V.D. 145'5. S.G. 2822 (Ritter, J. 8, 301). H.F. [P.O.Br.] = 108,000 from liquid Br; 120,000 from gaseous Br (Ogier, C. R. 92, 83).

Formation.—1. By the action of moist air or a very little H_oO on PBr₃ (Gladstone, P. M. [3] 35, 345)—2. By the action of oxalic or acetic acid on PBr₄ (Baudrimont, A. Ch. [4] 2, 58; Ritter, A. 95, 210).—3. By passing O into boiling PBr₃; explosions generally occur (Demole, Bl. [2] 34, 201).

Preparation.—To 137.5 parts PCl, are added 18 parts H₂O, and then 160 parts Br are added drop by drop, HBr and HCl are evolved, and POCl, and POBr, remain (part of the PCl, is decomposed to H₂PO, and HCl, and the H₂PO, Br, and remaining PCl, react, (?) thus 2PCl₂ + H₂PO₂ + 3Br₂ = 2POCl₃ + POBr₃ + 3HBr); the liquid is distilled, the portion boiling above 150° being kept separate and surrounded by a freezing mixture till it solidifies (Geuther a. Michaelis, LZ, 6, 242)

Michaelis, J. Z. 6, 242).

Properties and Reactions.—Large colourless plates, which melt and boil in dry air without decomposition; soluble in conc. H,SO, reppd. by H,O; soluble in CHCl., CS, ether, and turpentine. Decomposed rapidly by water to HBrAq and H,PO,Aq; bromine chloride forms POBrCl. or POCl., and Br, according to the quantity used (Geuther, J. Z. 10, 180); hydrogen sulphide probably forms PSBr; chlorine forms POCl. and Br; bromine seems to forme an additive compound which separates into POBr, and Br on heating (Gladstone, Lc.); tin and antimony remove Br (Baudrimont, Lc.).

Phosphorus, exybromechlorides of. Two of these compounds are known, but it is doubtful whether the second is a definite compound of a mixture of POOl₂ and POBr₂.

PHOSPHORUS OXYBROMODIGHLORIDE POBrCl. (Phosphoryl bromodichloride). Mol. w. 1974. Melts at 11°; boils at 1876 (Thorpe, C. J. 37, 848). S.G. & 2·12065 (Thorpe, L.c.). A colourless liquid, which solidifies, when cooled below 0°, to large colourless tablets which melt at 11°: when repeatedly distilled, or more quickly when heated in a closed tube to c. 185°, decomposed to POCl, and POBr, (Chambon, J. Z. 10, 92); decomposed by H₂O to H₂PO₂Aq, HClAq, and HBrAq; with a little alcohol forms POCl₂(OEt) and HBr. Prepared by the reaction of POBr, with BrCl in the ratio POBr, BrCl (Geuther, J. Z. 10, 130); by the action of PBr, on P.O.Cl. (G. a. Michaelis, J. Z. 7, 103). By reacting on P.OEt.Cl, with Br (Menschutkin, A. 139, 343); 80 g. Br are allowed to drop slowly into 74 g. P.OEt.Cl, kept well cooled and constantly shaken; the reaction is very violent; the POBrCl, is separated from the C.H.Br formed by fractionation (Thorpe, C. J. 37, 343). The P.OEt.Cl, is prepared by slowly dropping absolute alcohol into well-cooled PCl, in the ratio C.H.O: PCl, allowing to stand for some time, and fractionating; the boiling-point is 117°-118°.

PHOSPHORUS OXYDIBROMOCHLORIDE POBr,Cl (Phosphoryl dibromochloride). By the reaction of POBr, and BrCl, in the ratio POBr, : 2BrCl, Geuther (J. Z. 10, 130) obtained a liquid boiling between 150° and 160°, and decomposing very easily by heat into POCl, and POBr; analyses agreed with the formula POBr, Cl, but the liquid was possibly a mixture of POCl, and POBr, (3POBr, Cl = POCl, + 2POBr,).

Phosphorus, oxychlorides of. Two oxychlorides of P have been isolated, POCl, and P₂O₂Cl₄. A third substance obtained by Gustavson (B. 4, 853) by heating together P₂O₃ and POCl, and said by him to be PO Cl is declared by Michaelis (G. O. [1881] 2, 396) not to be a definite compound, and this is confirmed by Huntly (C. J. 59, 202).

PHOSPHORYL CHLORIDE POCI. Mol. w. 153-3.
Boils at 107-2° (Thorpe, C. J. 37, 337). Melts at -1.5° (Geuther a. Michaelis, B. 4, 769). S.G. $\frac{6^{\circ}}{4^{\circ}}$ 1.71163 (Thorpe, l.c.). V.D. at $150^{\circ} = 77.2$ (Cahours, A. Ch. [3] 20, 869). For expansion by heat v. Thorpe (l.c.). S.V. 101.4 (T., l.c.). H.F. [P,O,Cl³] = 145,960; [PCl³,O] = 70,660 (Th.

2, 325).

Formation.-1. By heating PCl, in air or O, or with ozone, SO, SO, Cl, and various other oxidisers.—2. By strongly heating PCl, in O, or with SO, SO, B,O, &c., or by decomposing by a little H,O.—3. By distilling NaCl mixed with P,O, (Kolbe a. Lautemann, A. 113, 240).—4. By passing CO and Cl over Ca, 2PO, mixed with C and heated to redness (Riban, C. R. 95, 110; Oglialoro, G. 13, 828).—5. By heating PCl, with P₂O₄.—6. By the reaction of Cl with P₂O₃ (Thorpe a. Tutton, C. J. 57, 572).

Preparation .- An intimate mixture of 1 part P.O. with 2.9 parts POl, is distilled, and the product is again distilled, that boiling at product is again distinct, that coming as 106°-108° being collected separately; the equation P₂O₂ + 8POl₂ = 5POOl₂ is realised.

Properties.—A colourless, highly refractive,

strongly smelling liquid, which fumes in the air; the fundes strongly affect the eyes and respira-tory organs; solidifies at -10°, when touched

with a glass rod, to long, colourless tablets, which melt again at -1.5° (Geuther a. Michaelis, B. 4, 769). POCl, does not conduct electricity even

when heated (Buff, A. 110, 257).

Reactions.—1. Water reacts rapidly, forming Reactions.—1. Water reacts rapidly, forming HClAq and H₂PO₂Aq [POCl², Aq] = 72,190 (Th. 2, 325).—2. Alcohol produces HCl and PO.OEt.Cl. 3. Sulphur trioxide at 160° forms P₂O₂Cl₄ and P₂O₃ (Michaelis, G. O. 2, 393).—4. Sulphuric acid produces SO, OH.Cl, HCl, and HPO, (Michaelis, .c.).-5. Most organic acids react similarly to H.SO., producing acid chlorides; e.g. C.H.O.OH forms C.H.O.Cl; salts of organic acids react similarly, forming acid chloride and metaphosphate.-6. Sulphates form SO Cl. and orthophosphates. -7. Sulphites are partially changed to SO2, mixed with metallic chloride and phosphate (Divers a. Shimidzu, C. J. 47, 208).— 8. Nitrates produce chlorides and P.O. &c.; 8. Nutrates produce chlorides and P₁O_s & O.

(D. a. S. l.c.).—9 POCl₃ separates I from potassism todide (Schiff, A. 102, 181).—10. Chromyl chloride forms Cl. P₂O₃, CrCl₃, and Cr,O₄ (Casselmann, A. 91, 241; 98, 213).—11. Phosphorus pentasulphide at 150° produces PSCl, and P₂O₃. 12. Phosphorus pentoxide reacts at c. 200°, forming P₂O₂Ol₄ and a substance P₂O₁Ol₃, which may prove to be a mixture (Huntly, C. J. 59, 202).— 13. Phosphorus reacts at 200° to form P₄O₂ POl₄. P₂O₃Cl₄, and a little P₂O₅ (Reinitzer a. Gold schmidt, B. 13, 845).—14. POCl₅ is reduced by heating in closed tubes with many finely divided metals, e.g. Ag, Hg, Fe, Cu, As (Pb is without action); the products are generally PCl, and P₂O₃, and oxide, chloride, or phosphate of the metal; sometimes P₂O₃Cl₄ is said to be formed (v. R. a. G., l.c.); Mg, Al, and Zn are said to form red P₄O (R. a. G., l.c.). Zinc-dust with a little POCl, forms Zn phosphide, which evolves inflammable P hydride on addition of a little water (Deniges, Bl. [3] 2, 787).—15. With ammonia forms various phosphumic acids (q. v., p. 105), and also phosphamides (q. v., p. 105).— 16. Boric oxide heated with POCl, in a sealed tube to 150°-170° for 8 to 10 hours forms P₂O₃.B₂O₄ and POCl₂.BCl₃ (Gustavson, B. 4, 975).

Combinations.—1. With ammonia to form a

compound not yet examined .- 2. With several metallic chlorides to form double compounds, e.g. with AlCl₂, MgCl₂, and SnCl₂ (Casselmann, A. 91, 241; 98, 213). Some of these compounds may be vapourised in absence of moisture; they are decomposed by water .- 3. With boric chloride also by heating POCl, with B₂O₈. This substance is decomposed by heat; with water it gives H,PO,Aq, H,BO,Aq, and HClAq (Gustavson,

B. 4, 975).

Constitution of POCl, —Two isomeric forms of POCl, are possible: Cl.POCl and Cl.PO; but the compounds obtained by different methods are identical. Wichelhaus (A. Suppl. 6, 257) thought that POCI, must have the constitution Cl.POCl, because of its formation from Cl.POEt. in which the O atom is in direct union with the P atom (Cl.POEt+Cl. = Cl.POCl+EtCl); but Geuther a. Michaelis (J. Z. 6, 242) pointed out that this formation of POCl, may be interpreted also in favour of the constitution Cl.PO by supposing that Cl first replaces OEt, forming PCl and that the POL and EtOCl then react :

(1) Ol.POEt + Ol. = Cl.P + EtOCl, (2) Cl.P + EtOCl = Cl.PO + EtCl. The experiments of Reinitzer a. Goldschmidt (B. 13, 845) on the action of metals, on POCl, show that in most cases O is withdrawn, leaving PCl.; and that in a few cases the 3 Cl atoms are withdrawn with formation of P₂O₅. These results do not indicate any differences between the functions of the Cl atoms, and hence they tend to favour the formula Cl₂PO. Thorpe (C. J. 37, 387) arrived at the formula Cl₂POCl from consideration of the specific volumes of BOCl, and PCl,. Masson a. Ramsay (C. J. 39, 50), also from considering the specific volumes of P and P compounds, deduced the formula OPCl3. Although but one POCl, has been obtained, the isomeric compounds $(C_gH_s)_gPOC_gH_s$ and $(C_gH_s)_sPO$ have been isolated (La Coste, B. 18, 2118).

PYROPHOSPHORYL CHLORIDE P.O.Cl. phorus trioxytetrachloride). Mol. w. not known. Boils 210°-215°, with partial decomposition. S.G. 1.58 at 7°.

Preparation .- 1. 100 g. PCl, are placed in a cylinder surrounded by ice and salt, and the vapour from 20 g. liquid NO, is passed into the cylinder by a tube which reaches just to the surface of the PCl. The action proceeds at once; the products are P.O., POCl., P.O.Cl., and NOCl. When all the NO, has been distilled into the PCl, the cylinder is placed in warm water to remove NOCI, and its contents are then fractionated; PCl, distils over first, then a considerable quantity of POCl, between 105° and 110°, and then P₂O₂Cl₄ from 200° upwards. is best to prepare a considerable quantity of the impure product before fractionating; 350 g. PCl, yielded 40 g. P.O.Cl. (Geuther a. Michaelis, B. 4, 766).—2. The vapour obtained by heating 30 g. starch with 180 g. HNO, Aq is led into 100 g. PCl,; the product is fractionated, and that boiling under 100° is again treated as before; finally, the whole is fractionated. About 20 g. P₂O₂Cl₄ are obtained from 200 g. PCl₂ (G. a. M., l.c.).

Properties.—A colourless liquid, which fumes in the air; the vapour attacks cork. Has not been solidified by cooling. Boils, with partial decomposition into P.O. and POCl., at 210°-

Reactions.—1. Heat produces partial decomposition into POCl, and P.O.,—2. Decomposed by water to H.PO.Aq and HClAq.—3. Alcohol produces PO.OEt.Cl, PO.OEt.(OH), and HCl. 4. Phosphorus pentachloride produces POCI, 5. Phosphorus pentabromide forms POBr, and POCI, Br (G. a. M., l.c.).

METAPHOSPHORYL CHLORIDE PO.Cl. Gustavson (B. 4, 853) said that a compound of this composition is formed by heating P₂O₈ with POCl_s; but Michaelis (G. O. 2, 396) says that the substance is not a true compound, and this is confirmed by Huntly (C. J. 59, 242).

Phosphorus, oxychlorobromides of, v. Phos-

PHORUS, OXYMOMOCHLORIDES OF, p. 142.
Phosphorus, oxyfluoride of, POF, (Phosphoryl fluoride). Mol. w. 108-92. V.D. 52 phoryl fluoride). Mol. w. 103-92. V.D. 52 (Thorpe, C. J. 55, 759; Moissan, Bl. [3] 4, 260). A gas which fumes in air and is rapidly absorbed by water. Formed by the reaction of P₂O₂ with fluorides (Schulze, J. pr. [2] 21, 438); also by exploding a mixture of 2 yols. PF, and 1 vol. O

by passing electric sparks (Moissan, C. R. 102, 1245); by gently heating an intimate mixture of 2 pts. finely-powdered cryolite with 3 pts. P.O. in a brass tube, and collecting over Hg as soon by NaOHAq (Thorpe, l.c.). Moissan (l.c.) prepares POF, by heating ZnF, with POCl, in a brass tube, fitted with a leaden delivery tube: he allows the gas to pass through a brass tube cooled to - 20°, and then over ZnF, to remove traces of POCI.

PÖF, liquefies at 16° under a pressure of 15 atmos., or at the ordinary pressure by cooling to -50° (M., C. R. 102, 1245). When compressed under 50 atmos. and the pressure then suddenly released, it solidifies to a snow-like mass. When quite dry it is without action on glass or Hg; heated in a glass tube SiF, and an alkaline phosphate are formed.

Phosphorus, oxyiodide of, P.I.O. (Am. 3, 280) obtained a red crystalline compound, to which he gave this composition, as a by-product in preparing C2H.I. M.P. c. 140°; sublimable, with partial decomposition; e. sol. water, alcohol, and ether.

Phosphorus, oxynitride of PON (Phosphoryl nitride. Phosphoryl nitride. Formerly called Phosphomonamide). Mol. w. uncertain. A white powder, which melts at red heat to black glass-like mass. Obtained by heating PO(NH.). or PONHNH,, the former of which is formed by the reaction of POCl₃ with NH₃, and the latter by the reaction of PCl₃ and NH₂ (Schiff, A. 101, 300; of. Phosphamides, p. 105). Gives K₃PO₄ and NH, by action of molten KOH (v. also Gladstone, C. J. [2] 7, 18).

Phosphorus, selenides of. P and Se combine directly to form four compounds: P.Se, P₂Se, P₂Se₃, and P₂Se₅. P2Se, P2Se3, and P₂Se, combine with the selenides of the more positive metals to form compounds R, Se.P, Se, (R,Se), P,Se, and (R,Se), P,Se, The formulæ are not necessarily molecular.

PHOSPHORUS SUBSELENIDE P.Se (Phosphorus hemiselenide). Prepared by melting together Se and ordinary P in the ratio Se: 4P(1:1-57) in an atmosphere free from O, and separating from amorphous P by distillation in absence of O. A dark yellow, oily, fetid-smelling liquid, which solidifies at -12°; e. sol. in CS, insol. alcohol and ether; takes fire in air; decomposed by water containing air, with formation of H, PO, Aq and Se compounds; not acted on by cold alkali solutions, but with boiling alkali solutions gives alkali phosphate and selenite, metallic selenide and P hydride; in solutions of metallic salts becomes covered with a crust of metallic phosphide and selenide (Hahn, J. pr. 93, 430).

DIPHOSPHORUS SELENIDE P.Se. (Phosphorus Prepared by protoselenide or monoselenide). Prepared by melting together, in absence of O, P, and Se in ratio 2P: Se(1:128). A red solid; unchanged in dry air, in moist air gives off H2Se; insoluble alcohol and ether; P is withdrawn by CS2; boiling alkali solutions produce H. Se and a red sub-stance containing Se and P. By heating, in absence of O, with equivalent weights of metallic selenides, compounds R' Se.P Se and R' Se.P Se are formed; R=Ba, Cu, Fe, Mn, K, Ag, Na. The alkali compounds are decomposed by water; the compounds containing heavy metals decompost only at high temperatures, but they generally take fire when rubbed in a mortar; they are slowly decomposed by hot alkali solutions (Hahn, L.). From their empirical composition, R¹PSe, these compounds might be called seleno-meta-kypophosphites.

PROSERIOROUS SELENDE P.Se. (Phosphorus assistational or trisclevide). Prepared by heating together P and Se in ratio 2P:3Se(1:3-82) in absence of O. A dark ruby-red solid; sublimes to yellow vapours when heated out of O; burns when ignited in air. Oxidised slowly in moist air; evolves H₂Se when boiled with water. Insoluble alcohol, ether, and CS₂; easily soluble in potash, less soluble in alkali carbonate solutions. Forms compounds with metallic sclenides (R', Se)_P, Se, and 2R', Se, P, Se, (Hahn, Lc.); R = Ba, Cu, Pb, Mn, K, Ag, Na. From their empirical composition, R', P, Se, these compounds might be called selenopyrophosphites.

Phosphorus SELENDE P. Se. (Phosphorus

PHOSPHOROU SELENINE P₂Se₃ (Phosphorus pentaselenide). Prepared by heating together amorphous P and Se in ratio 2P:5Se (1:6:37) in a stream of CO_x. A dark-red, nearly black, glasslike solid; insoluble in CS₂; crystallises from CCl₄ in black needles. In moist air, or water, decomposes slowly to H₂Se and H₂PO₄Aq; in cone. KOHAq quickly forms K₂Se and K₂PO₄Aq; alcohol forms H₂Se and Et₃PO₂Se₂ and also Et₄HPO₂Se₂. Very unstable compounds probably of the forms (R¹₂Se), P₂Se₃ and 2R¹¹Se, P₂Se₃, are obtained by heating P₂Se₃ with metallic selenides; R - Ba, Cu, Pb, Mn, K, Ag, Na. The empirical composition of these compounds would lead to the name selenopyrophosyhales (Bogen, A. 124, 57; Rathke, A. 152, 200). Rathke (l.c.) supposed that the K salt of a selenophosphoric acid is formed by the reaction of P.Se, with KOHAq.

Phosphorus, selenion acids of, salts of; D. Diphosphorus selenide, Phosphorus selenide, and Phosphorus, sulphides of. P and S combine,

Phosphorus, sulphides of. P and S combine, when heated together, with production of much heat and light; the action is often violently explosive. Four definite compounds seem to exist; the simplest formulæ are P₄S₃, P₂S₂, PS₂, and P₂S.

P₂S.

Two compounds containing less S than P₄S₃, viz. P₂S and P₄S, are often described, and substances said to be compounds of P and S in the ratio P:3S and P:6S have been mentioned by Dupré and Berzelius.

The substance to which the formula P.S was given was obtained by heating P and S in the proper proportions (Berzelius, A. 46, 129, 255), or by digesting P with an alcoholic solution of K.S. (Böttger, J. pr. 12, 357), or according to Wicke (A. 86, 115) by contact of P and S at ordinary temperatures; it was described as a colourless, oily liquid. A solid red form of P.S was said to be formed by heating liquid P.S with Na.CO. (Berzelius, L.). The formula P.S was given to a substance of which two forms were described: a yellow liquid obtained by carefully heating together P and S in the proper ratio, and a dark-red powder obtained by beating the liquid form with dry MnS in JH (Berzelius, L.): Various double compounds of P.S with metallic sulphides, B.S.P.S and R.B.P.S (B = Cu. Fe, Mn, Hg, Ag) were described by Berzelius. The composition of these bodies

would lead to their being called thiometahypophosphites. Isambert (C. R. 96, 1771) has shown that when a solution of P in a large excess of S is distilled in vacuo the whole of the P passes off and leaves S. Schulze (J. pr. [2] 22, 118) found that P separated at 8° from a solution of S in P in the ratio P.S, and that S separated when the elements were present in the ratio P₂S. Schulze also found that a stream of CO₂ removed P from both solutions at 150°; that heating to this temperature generally produced explosions that the so-called liquid P₂S was soluble in CS₂, and that most of the S was removed by shaking this solution with alcohol, ether, or CHCl. Further, Schulze (B. 16, 2066) observed that solutions of S in P, in the ratio P.S and P.S. did not solidify homogeneously. but that P separated from the first, and S from the second, solution. From these facts Isambert and Schulze concluded that the so-called P.S and P.S are merely solutions of S in P. Lemoine (C. R. 96, 1630) maintained that these substances were true compounds. According to Mai (A. 265, 192), when 67 parts P and 96 parts S are melted together, and the product is dis-tilled at 10-11 mm. pressure, a distillate is obtained which slowly solidities, and digestion of this solid with CS₂ under pressure gives a solution from which crystals of P₄S, separate, and the mother-liquor deposits what seems to be a mixture of P.S. and P.S. The melting-points of mixtures of P and S are much below those of either constituent (Pelletier, A. Ch. [2] 4, 1; Faraday, A. Ch. [2] 7, 71; Dupré, A. Ch. [2] 78, 435). The experiments of Faraday (l.c.) and Ramme (B. 12, 940, 1350) show that the crystals obtained by dissolving S in liquid P sulphides to which Berzelius gave the composition PS, and Dupré the composition PS, are merely S with more or less adhering P.

TETRAPHOSPHORUS TRISULPHIDE P.S. (Sesquisulphide of phosphorus. Hypophosphorus sulphide). Mol. w. 219-3. Melts at 166° (Ramme B. 12, 1350). Boils at 380° (Isambert, C. R. 96, 1499). S.G. 2-0 at 11°. V.D. 114-3 (Isambert, Lc.; Ramme, lc.). H.F. [P',S'] = 36,800 (L., lc.). Formation.—1. By heating together P and S

Formation.—1. By heating together P and S in the ratio 4P:3S.—2. By heating P₄S₆ with ordinary P to 320° (Ramme, l.c.).

Preparation.—A mixture of 1 part S with 13 parts amorphous P is placed in a flask with a long wide neck connected with a wide tube dipping beneath the surface of Hg; the mixture is heated towards 260°, when the reaction begins, and proceeds with production of much heat; the product is dissolved in CS, and crystallised (Lomoine, BL. [2] 1, 407). Ramme (B. 12, 1360) heats the rod P and S together in a scaled tube at 260° for eight hours. If ordinary P is used, combination occurs at 130°, with violent explosion. The explosion may be prevented by melting the S and P in the water-bath, and adding twice as much sand from which air has been removed by CO₂ (Isambert, C. R. 96, 1499). Ramme (B. 12, 1351) obtained P₂S, by heating P₂S, with ordinary P in a sealed tube, filled with CO₂, to 320°.

CO, to 320°.

Properties.—A yellow crystalline solid, which melts at 167° to a slightly coloured liquid. Boils 230°-240° at 11 mm. pressure, with 'partial decomposition to red P (Mai, A. 265, 192). 'Crys.

tallises from CS₂, PCl₂, or PSCl₃ in rhombic prisms (Lemoine, BL [2] 1, 407); sublimes under 800°, probably in regular crystals (Isambert, C. R. 96, 1499). Very soluble CS₂, PSCl₃, and PCl₄; dissolved and decomposed by alcohol (Lemoine, l.c.). Burns at c. 100° to P₂O₃ and SO₂; scarcely changed in ordinary air.

scarcely changed in ordinary air.

Reactions.—1. Burns when heated in air to c. 100°, forming P₂O₃ and SO₇—2. Not acted on by cold water; hot water slowly produces HS and H₂PO₂Aq.—3. Dissolves in potash solution, forming K phosphite and sulphide, and evolving H and P hydride (Lemoine, l.c.).—4. Hydrated lead oxide reacts at 200° with separation of PbS (L., l.c.).—5. Soluble in potassium sulphide solution, probably with formation of a double compound (L., l.c.).—6. Chilorine, when moist, slowly produces H₂SO₄ and H₂PO₄ (L., l.c.; I., l.c.).—7. Not acted on by cold sulphuric or hydrochloric acid; nitric acid and aqua regia oxidise P₂S₄ slowly and regularly on warming.

P.S. slowly and regularly on warming.

PHOSPHOROUS SULPHIDE P.S. (Trisulphide of phosphorus. Tetraphosphorus hexasulphide. Thiophosphorous anhydride). Mol. w. 315-72.

Melts at c. 200°, and boils at c. 490° V.D. 147-5, to 173-6 at lower temperatures (Isambert,

C. R. 102, 1386).

Formation.—1. By heating red P and S in the ratio 2P:3S in CO₂. Combination occurs without explosion, but so much heat is produced that a part of the product sublimes rapidly (Kekulé, A. 90, 310; Michaelis, A. 164, 22).—2. By the reaction of PCl₃ with H₂S (Serullas, P. 17, 101). Ramme (B. 12, 940) failed to obtain P₄S₆ by heating a solution of P and S in CS. in a sealed tube.

tain P,S₂, by heating a solution of P and S in OS₂ in a sealed tube.

Preparation.—A mixture is made of 1 part red P with 1.55 parts S; a small portion of this mixture is heated in a long-necked flask in a stream of CO₂ until combination occurs; the flame is removed, and the rest of the mixture is introduced into the flask in small portions at a time; the heat produced by the combination of one quantity suffices to cause combination of the next quantity. The P₄S₄ is sublimed into the neck of the flask; or it may be dissolved in CS₂ and crystallised (Michaelis, A. 164, 22).

Properties.—A greyish-yellow, crystalline, solid (Kekulé, A. 90, 310; Isambert, C. R. 102, 1386). Tasteless, inodorous; does not fume in air; melts readily (c. 200°), and sublimes more easily than S. Soluble in CS... The V.D. shows that the molecular formula is P.S., corresponding with the oxide P.Q.. P.S. acts as a thio-anhydride, forming compounds with the sulphides of several metals (v. Reactions, No. 7). As P.S. is acted on by moist air, it must be kept in sealed tubes.

Reactions.—1. Decomposes rapidly in moist air (? to H₂S and H₂PO₂).—2. Decomposed by water to H₂S and H₂PO₂Aq.—3. Burns when heated in air.—4. Dissolves in potash, soda, or ammonia solution, and is reppd. in yellow flocks by addition of soid.—5. Decomposes carbon compounds containing OH, forming corresponding SH compounds and H₂PO₂.—6. With todine in CS, forms PI₂ (Isambert, C. R. 96, 1771).—7. According to Berzelius, P₂S₃ combines with many metallic sulphides forming compounds 2R¹₂S.P₂S₃ and 2R¹S.P₂S₃ the compounds 2R²S.P₂S₃ and 2R¹S.P₂S₃ the compo-

sition of which would lead to their being calle thiopyrophosphites; R=Cu, Fe, Hg, Ag.—8. B dissolving in caustic scda solution cooled to 0° Lemoine (C. R. 93, 489; 98, 45) obtained th compound P.OS., 2NA, 0.5H₂O and the compound P.OS., 2NA, 0.5H₂O and by using ammonium sulphide he obtained P.OS., 2(NH.), 20.8H₂O and P.OS., 2(NH.), 20.6H₂O. These substances evolved H.S by the action of HClAq; heated to 200°. 240° they gave off H.S. but retained S; they may perhaps be called thio-oxypyrophosphites.

Triphosphorus hexasulphide P_9S_6 (Phosphorus disulphide $[PS_2]$). Phosphorus tetra sulphide $[P_2S_1]$). PMol. w. 284*8. Melts at 296°-298° (Ramme, B. 12, 940); at 248°-249° (Seiler Dissertation, Göttingen, 1876). Boils at 335°-340° at pressure of 10-11 mm. (Mai, A. 265. 192). V.D. Ramme (B. 12, 1350) says that V.D. agrees with formula P_2S_6 , but no numbers are given.

Formation.—1. By heating a solution of P and S in CS₂ in sealed tubes to 210°; according to Ramme (B. 12, 940), P₂S₆ is produced with P and S in the following ratios:—P.S, P:2S, 2P:S, 3P:S, 4P:S, 6P:S (v. also Dervin, Bl. [2] 41, 433).—2. By heating together P and S in the ratio P:2S (Seiler, l.c.).

Preparation.—P and S are dissolved in CS₂ in the ratio P: 2S, the solution is heated in a sealed tube to 210° for 8-10 hours, after cooling the liquid is poured off, and the crystals are recrystallised repeatedly from CS₂ in a sealed tube (Ramme, Lc.).

Properties and Reactions.—Long, clear yellow, needle-shaped crystals. Ramme (l.c.) says that V.D. corresponds with formula P₂S₆ but he gives no data; the corresponding oxide is generally written P₂O₆, but its molecular weight has not yet been determined. Heated with water in a sealed tube to 150° for some hours, P₂S₆ gave H₂S, H₂PO₄Aq, and H₂PO₄Aq and an orange-yellow solid insoluble in CS₂ and not melting at 310° (Ramme, B. 12, 1350).

PHOSPHORIO SULPHIDE- P.S. (Phosphorus pentasulphide or persulphide. Thiophosphoric anhydride). Mol. w. 221-8. Melts at 274°-270° (V. a. C. Meyer, B. 12, 610). Boils at 518°, pressure z 730 mm. (Goldschmidt, B. 15, 603); at 520° (Isambert, C. R. 102, 1386); at 530° (Hittorf, P. 126, 196); at 332°-340°, pressure being 11 mm. (Mai, A. 265, 192). V.D. 110-7, at 530° in N (V. a. C. Meyer, B. 12, 610).

Formation.—1. By heating a solution of ordinary P and S, in the proper ratio, in CS₂ to 210° for 8-10 hours, and crystallising from CS₂ (Ramme, B. 12, 940).—2. By melting together red P and S, in ratio 2P:5S, in CO₂ (Kekulé, A. 90, 310); with ordinary P violent explosion occurs.

Preparation.—A mixture of 40 parts S and 18-5 parts red P is melted together, the mass is powdered, placed in a retort filled with CO₂, and distilled to c. \(\frac{1}{2} \) to \(\frac{1}{2} \) (to remove_0 P, S, and more volatile P sulphides); the residue is again powdered and distilled in CO₂; the distillate is pure P,S, (V. a. C. M., l.c.).

P.S. (V. a. C. M., l.c.).

Properties.—Large, clear, pale-yellow crystals. Vapourises in N or CO, without change, to a yellowish gas. Burns when heated in air.

Soluble in OS₂; P₂S₃ seems to react as a thio-anhydride (v. Reactions, No. 7).

Reactions.-1. Decomposes in moist air or by water, to H₂S and H₂PO₄; burns when heated in air to P₂O₂ and SO₂—2. With phosphorus pentachloride forms PSCl₃ (Weber, J. 1859, 80). 8. With carbon tetrachloride at 200° produces CS₂ and PSCl₃ (Rathke, Z. 1870, 57).—4. With ferric chloride gives FeS₂ and PSCl₃ (Glatzel, B. 23, 37).—5. With sulphonyl chloride, PSCl₃, SO₂, and S are formed (Prinz. J. Z. 13. Supplbd. 1. 90).-6. With many carbon compounds containing O and also with many inorganic oxides, P.S. form S compounds, exchanging S for O (Kekulé, A. 90, 310; Carius, A. 106, 331; 112, 180; v. also Prinz, l.c.).—7. According to Berzelius (A. 46, 129, 255), P.S. combines directly with several metallic sulphides, forming compounds $2R_{12}S_{1}P_{2}S_{3}$ and $2R_{11}S_{11}P_{2}S_{3}$ (R = Cu, Fe, Mn, Hg, Zn): these compounds may be called thiopyrophosphates.

THIO-OXYORTHOPHOSPHATES. Salts of the hypothetical acids II PSO, (monothio-oxyorthophos-phoric acid) and H.PSO, (dithio-oxyorthophosphoric acid) have been obtained by the action of alkali solution on P.S., or on PSCI. Salts of trithio-oxyphosphoric acid (H,PS,O) have not

been isolated.

Monothio-oxyphosphates. The Na salt, Na PSO .. 12II O was obtained by Wurtz by warming PSCI, with fairly conc. NaOHAq (A. Ch. [3] 20, 472), and by Thorpe a. Rodger by the ac-16) 20, 412, and by Interpe a. Rodger by the action of NaOHAq on PSF₃ (C. J. 55, 318). Kubierschi (J. pr. [2] 31, 93) obtained the salt by adding powdered P.S. to NaOHAq, in ratio P.S. 6NaOH, cooling, adding absolute alcohol which ppd. a mixture of Na, PSO, and Na, PSO, (leaving Na polysulphides in solution)-dissolving the pp. in water, warming to 90° till H S ceased to come off, evaporating, and crystallising. Thin ax-sided prisms, melting at 60°. The Mg salt (with 20H,O), and the Mg-NH, salt (with 9H2O) were also obtained.

Dithio-oxyphosphates. The Na salt, Na,PS,O,11H,O was obtained (K., l.c.) by dissolving in water the pp. obtained as above by alcohol, warming to 50°-55°, ppg. by alcohol, and crystallising from water at 40°. Colourless, lustrous, needles, melting at 45°-46°. The NH salt (with 2H₂O), Ba salt (with 8H₂O), and Mg-NH, salt (with 6H₂O) were also obtained in

crystalline form.

For reactions of these thio-oxyorthophosphates v. Kubierschi, l.c. (cf. Michaelis, B. 5, 5). Phosphorus, sulphobromides of. Two compounds, corresponding with the two oxychlorides, have been prepared.

THIOTHOSPHORUL BROMIDE PSBr. (Sulphophosphoryl bromide. Phosphorus sulphobromide). Formula probably molecular, from analogy of

POCI,

Formation .- 1. By reaction of H.S with PBr. (Gladstone, P. M. 35, 345; Baudrimont, A. Ch. [4] 2, 58).—2. By distilling PBr, with S, or Br with P₂S₂.—3. By the action of Br on a solution

of P and S in CS.

Preparation.—Equal parts of P and Seare adissolved in CS, the solution is well cooled, and 8 parts Br are allowed to drop in slowly from a funnel with a stopcock; the CS, is removed by warming in a water-bath, and the liquid is then

distilled quickly over a large flame. Part of the PSBr, solidifies in the neck of the retort, and part passes over and remains liquid in the receiver; the contents of the receiver are shaken with fresh quantities of water until the oily liquid solidifies to a yellow crystalline mass which is PSBr, H,O; this hydrate is dissolved in CS, water is removed by contact with CaCl, is distilled off in a stream of CO, and CS PSBr, remains as a yellow oil, which solidifies on touching it with a glass rod. The solid may be recrystallised from PBr_s (Michaelis, A. 164, 36).

Properties .- Yellow octahedral crystals, with an aromatic but unpleasant odour; vapour attacks the eyes. Melts at 38°, when molten remains for a long time without solidifying unless touched by a solid (Michaelis, B. 4, 777). Easily soluble in ether, CS₂, PBr₃, or PCl₄. Cannot be distilled without decomposition.

Reactions .- 1. Decomposed by heat to S and a yellow liquid, PSBr, PBr, which is resolved by repeated distillation into S and PBr, and by repeated washing with water yields PSBr. H.O peated washing with waters yields PSBr_s,H₂O (Michaelis, A. 164, 36).—2. Decomposed by water, slowly when cold, rather more rapidly when boiling, forming H₂S, S, H₂PO₂Aq and H₂PO₄Aq (v. Michaelis, B. 5, 4).—3. With alcohol forms PS(OEt)₃.—4. Decomposed by ammonia solution, slowly when cold, more rapidly when hot, giving NH₄ phosphite and phosphate, H₂S, S, and NH₄ sulphide (M., Le.).

Beacts with hypotherus poutachleride to 5. Reacts with phosphorus pentachloride to form PSCl₂ and PBr₃ (M., l.c.).

Combinations. — 1. With water to form

PSBr₃.H₄O (v. Preparation). A yellow crystal-line solid; melts at 35°, being resolved into H₄O and PSBr_s; S.G. 2.7937 at 18°; gradually decomposes in air, giving off HBr (Michaelis, A. 164, 36).—2. With phosphorus bromide to form PSBr, PBr,; obtained by heating PSBr, (v.

Reactions, No. 1).

Pyrophosphonyl bromide P2S3Br4 (Phosphorus trisulphotetrabromide). A light-yellow oil, with aromatic and pungent odour; S.G. 2.2621 at 17°; fumes in air, with separation of S. Decomposed by distillation into S, P,S, and Decomposed by distillation into S, P.B., and PSBr., PBr.; decomposed by water, giving S, PSBr., H₂S, P, and a substance probably P.S.₁(OH)₄; alkalis act similarly to, but more violently than, water, but neither S nor PSBr, is formed; with absolute alcohol yields P₂S.₁(OEt)₄Br, P₂S.₂(OEt)₄, P₂S.₃(OEt)₄(SEt)₅; bromine reacts, when heated, forming PBr, and PSBr. (Michaelis A 16A 29). Prepared by PSBr. (Michaelis, A. 164, 22). Prepared by moistening 100 g. finely powdered P.S. with CS. and adding 200 g. Br diluted with an equal volume of CS2, shaking thoroughly, distilling off CS2 in water-bath not above 80°, removing last traces of CS, in stream of CO, dissolving residue in six times its volume of dry ether, and removing ether

by a stream of CO₂ (M., l.c.).

Phosphorus, sulphobromochloride of, PSBrCi. (Thiophosphoryl bromochloride). probably molecular, from analogy of POBrCl. (Michaelis, B. 5, 6). A slightly yellow liquid, with aromatic odour; boils c. 150°, but boilingpoint soon rises and S separates. Decomposed slowly by water, more completely when heated in a sealed tube to 150° for some hours, giving S, H₂S, HClAq, HBrAq, H₂PO₂Aq, and H₂PO₄Aq. Prepared by adding 80 parts Br

drop by drop to 168 parts PCL.SEt [obtained by action of EtSH on PCl,; for details v. Michaelis, etc.]; much heat is produced; the liquid is distilled, the distillate from 150°-180° is shaken with water so long as any action takes place; water is removed by a separating funnel; the liquid is dried by CaCl, and HCl and HBr are removed by warming gently (M., l.c.).

Phosphorus, sulphochlorides of. But one compound, PSCl, is known with certainty. It is doubtful whether the substance obtained by Gladstone (C. J. 8, 5) by the reaction of S with PCl, is a definite compound PS,Cl,, or a double

compound PSCl. SCl.

THIOPHOSPHORYL CHLORIDE PSCI₂ (Phosphorus sulphochloride), Mol. w. 169 05. Boils at 125·12° (Thorpe, C. J. 37, 341). S.G. 40 1·6682 (T., l.c.). V.D. 85 at 160°-300° (Cahours, A. Ch. [3] 20, 869; Chevrier, C. R. 68, 1174). For thermal expansion v. Thorpe (l.c.). S.Y. 116·1.
 Formation.—1. By the reaction of H₂S with

PCI, (Serullas, A. Ch. [2] 42, 25).—2. By heating S with PCl₂ to 130° (Henry, B. 2, 638).—3. By heating P with S_cCl₂ (Wöhler a. Hiller, A. 698, 274).—4. By heating together P_cS_c and PCl₃ (Weber a. Thorpe, Z. 1871, 467).—5. By the re-(Weber a. Inorpe, Z. 1871, 407).—5. By the reaction of PCl, with SO, SO,Cl., or S,Cl.; and by the reaction of PCl, with CS, or with Sb,S, (Michaelis; Cairns, A. 112, 190; 119, 291; Rathks, Z. 1870, 57; Baudrimont, J. pr. 87,

801).

Preparation.—An intimate mixture of P.S.

Preparation.—An intimate mixture of P.S.

1.2 B.S. APCL (= 1:2 82), is and PCla, in the ratio P2Sa: 3PCla(=1:2.82), is heated in a sealed tube to c. 120°; after a short time the liquid which has formed is distilled. Should the product have a yellowish colour, it is shaken with a little water, dried by CaCl, and distilled. The equation P.S. + 3PCl, = 5PSCl. is realised (Thorpe, C. J. 37, 341).

Properties. - A colourless, highly refractive liquid; with an aromatic, somewhat pungent, and very peculiar odour, which becomes very marked on warming. Slowly decomposed by water.

Reactions. -1. Very slowly acted on by water, with formation of H₂PO₁Aq, HClAq, and H₂S. When distilled in steam the greater part of the PSCl, passes over unchanged.—2. Heated with alcohol under pressure, PS(OEt), is formed.—3. Passed through a hot tube, with excess of hydrogen sulphide, P.S. and HCl are formed (Baudrimont, J. pr. 87, 301).—4. Decomposed by chlorine with formation of S.Cl. and PCl. Silver nitrate reacts rapidly, producing Ag.PO., AgCl, SO., NOCl, and NO. (the SO. and NO. then reacting to form S.O.(NO.);; Thorpe B. Dyson, C. J. 41, 297).—6. Alkali solutions form salts of H.PSO. and H.PS.O. (v. Thio-OXYORTHOPHOSPHATES, p. 147) .- 7. The prolonged action of ammonia—continued until 60 p.c. of the PSCI, has reacted with the NH,—produces thiophosphamids PS(NH2):(?); this compound remains as an amorphous, yellow-white solid on washing the product of the action of NH on PSCl₂; B.G. 1.7 at 13°; decomposed at 200°, gives (?)PS(ONH₄), with hot water (Chevrier, C. R. 66, 748; Sohiff, A. 101, 292). Accordring to Gladstone a. Holmes (C. J. 18, 5), thio-phosphamic acid PS(NH₂)(OH), and thio-phosphodiamic acid PS(NH₂)₂OH, are pro-

duced by the action of ammonia on PSCI,; the former by using fairly dilute NH,Aq, and the latter by using NH, gas—which probably forms P(NH₂),ClS—and then washing with water. The work of Chevrier (l.c.) and Schiff (l.c.) makes the isolation of these acids doubtful.

Phosphorus, sulphochlorobromide of; Риовриовия вигриовкомоситовите, р. 147.

Phosphorus, sulphocyanide of, P(SCN), (Phosphorus thiocyanate. Phosphorus rhodan-Mol. w. not determined; formula probably molecular. Prepared by mixing 5 parts Pb(SCN), with an equal weight of dry sand, gradually adding 1 part PCl₃, digesting for some time on a water-bath, and then distilling very carefully from a hard glass tube. A liquid which does not solidify at -- 20°, begins to boil 260°-270°, and decomposes at a higher temperature, giving off CS,; vapour is spontaneously inflammable; S.G. 1.625 at 18'. Soluble in alcohol, ether, CHCl₃, CS₂, and C₆H₆. Slowly decomposed by cold water to H₂PO₃Aq and HSCNAq (Miguel, A. Ch. [5] 11, 349).

Phosphorus, sulphofluoride of, PSF, (Thiophosphoryl fluoride). This compound was prepared and fully described by Thorpe a. Rodgers in 1888 (preliminary notice in C. J. 53, 760; fuller account in C. J. 55, 306). Mol. w. 119.9.

V.D. 59 6 at ordinary temperature.

Formation.—1. By heating a mixture of AsF₃ and PSCl₃, in ratio AsF₃: 4PSCl₃, in a sealed tube at 150°.—2. By heating PbF₂ mixed with P₂S₃ to c. 120°-150°; or by using BiF₃ in place of PbF, and heating to a higher temperature. A mixture of red P, S, and a large excess of PbF, may also be used $(P_aS_a + 3PbF_a = 3PbS + 2PSF_g)$. 3. By heating S with PF_aCl_a to 115° (Poulenc, C.R. 113, 75).

Preparation.-A quantity of P.S. (freshly prepared from well-washed and perfectly dry amorphous P and roll S) is quickly mixted with c. 33 parts of pure freshly fused PbF2, and the mixture is placed in a thin equal layer in a dry tube of lead or 'composition,' one end of which is fitted with a caoutchouc oork carrying a glass delivery tube dipping under dry Hg, and the other end is connected with an apparatus for supplying pure dry N. A rapid stream of N is passed through till the air is driven out, the tube being gently heated to get rid of traces of H.S (produced by moisture on P.S.); the N is stopped, and the tube is heated from behind forwards by a small flame; reaction begins c. 170°; the temperature should be kept as low as possible, it must not exceed 250°. The gas is collected in a dry glass gas-holder containing a few small pieces of quicklime, the gas being allowed to pass into the holder as soon as a sample is wholly absorbed by dilute potash or ammonia. Before collecting the gas, small quantities of dry N should be passed into the gasholder and repeatedly exhausted by the Sprengel pump (this removes air from the pores of the lime), and when 2 or 3 c.c. of the PSCl, have passed into the holder the gas should be sucked out by the Sprengel, and this repeated twice or thrice (the traces of N are thus removed). After standing a few days over the lime, which removes PF. and any traces of SiF, the gas is pure PSF,

Properties,—A transparent, colouriess gas; liquefied at 7.6 atmos. at 3.8°, 9.4 atmos. at 10°,

10.3 atmos. at 18.6°, and 18 atmos. at 20.3°. PSF, is spontaneously inflammable in air or O it is decomposed easily by heat or electric sparks to S, P, and fluorides of P. Somewhat soluble in ether. Not easily dissolved by H₂O, or by solutions of alkalis. No action on Hg, H₂SO, CS₂, or C₆H₆. Neither gaseous nor liquid PSF, acts appreciably on glass at ordinary temperatures.

Reactions. -1. A small stream of PSF, issuing from a Pt jet into air at once takes fire; when mixed with a large volume of air, explosion occurs.-2. Oxidised rapidly and explosively by oxygen; probably with formation of PF, and SO, the PF, and O then producing P₂O, and also POF₃. The ignition-temperature of PSF₃ is very low, and the flame is a very cold (Full details are given by T. a. R., I.c., pp. 312-317.)—3. Slowly decomposed by water, thus: $PSF_3 + 4H_2O + Aq = H_2S + H_3PO_1Aq + 3HI_1Aq.$ 4. Solution of potash or soda slowly reacts, forming Na₂PSO₃ and NaF.—4. With ammonia gas produces a white, deliquescent solid, probably a mixture of NH₁F and P(NH₂)₂SF. For action of water on this substance-perhaps resulting in formation of PS(NII2)2OH-v.T.a.R., l.c., p. 319.—5. Heated in a glass tube, PSF, gives SiF, P, and S.—6. PSF, is decomposed by electric sparks passed from Pt terminals, with separation of S and P, and a gas which is probably PF..

Phosphorus, sulphoselenide of. All attempts to prepare this compound have led to negative results. Michaelis heated PCl, with Se; Bandrimont (A. Ch. [4] 2, 5) tried the reaction of PCl, with SeCl, PCl, with P.Se, Sh.Se, and PbSe, and the action of P on SeCl, and SeCl,

Phosphorus, sulphoxide of, $P_iO_aS_i$. Mol. w. 34752. Melts at 102°, and boils at 295°. V.D. 171:3 at 350°-400°. Formed by heating small quantities P_4O_a with S in an atmosphere of CO_2 or N at c. 160° (Thorpe a. Tutton, G. J. 59, 1022).

Preparation .- A strong glass tube is closed at one end, and filled with dry CO, or N; from 3 to 5 g. freshly-distilled PAO, is placed in the bottom of the tube, and 1.74 g. S, best in small crystals, are added for every 3 g. P.O. used (ratio P.O.: 48). The tube is sealed, and the lower half is immersed in a glycerin-bath, which is gradually heated. At c. 154°-165° the melted S is suddenly projected to the top of the tube, and in a few seconds the action is complete. The product is transferred to a similar tube, which is exhausted by a Sprengel pump, sealed, and warmed at its lower portion; sublimation begins at c. 90°, and proceeds best at 140°-150°, with formation of long feathery needles; part of the P.O.S. remains as a vitreous or crystalline mass.

Properties and Reactions.—A white solid, occurring in feathery aggregations or a vitreous mass, or as colourless, isolated, tetragonal prisms; melts 102°, and boils 295° (cor.). Very deliquescent, smelling in air of H₂S; quickly dissolved by water, forming H₂S and HPO₂Aq, which soon changes to H₂PO₄Aq. Easily sol. in 2 vols. CS₂ from which it crystallises unchanged. Also sol. benzene, but with decomposition.

Phosphorus, sulphur acids of, salts of; v. beginding of article Phosphorus sulphides

(p. 145); Phosphorous sulphide, Reactions 7 and 8 (p. 146); Phosphoric sulphide, Reaction 7 (p. 147); and Thio-oxygethophosphares (p. 147).

Phosphorus, telluride of. Oppenheim (J. 1857, 214) obtained a black amorphous solid, giving off fumes of P₂O₂ in air by heating P with powdered Te.

Phosphorus, thio-acids of, salts of; v. beginning of article Phosphorus suppurpus (p. 145); Phosphorus sulphide, Reaction 7 (p. 140); Phosphorus sulphide, Reaction 7 (p. 147); and Theo-exvormorhosphares (p. 147).

SULPHOCYANIDE, p. 148. • Phosphorus, thioselenide of; v. Phosphorus Sulphoselenide, ante.

M. M. P. M.
PHOSPHORUS, OXYACIDS OF, AND THEIR
The three phosphoric saids H PO

SALTS. The three phosphoric acids, H₂PO₄, H₄P₂O₇, and HPO₄, are described under Phosphono acids (p. 124); the salts of these acids are described under Phosphates (p. 108); the other oxyacids of P₄ and their salts, are described in this article.

Besides the phosphoric acids, three oxyacids of P, and some salts of a fourth acid, have been isolated; the acids in question are H₂PO₂, H₂PO₃, H₂PO₃ or H₁P₂O₄; and salts of H₂PO₃. No anhydride of H₂PO₄ is known; the hypothetical anhydride would be P₂O (P₂O + 8H₂O - 2H₂PO₃); P₂O₄ is the anhydride of the acid H₂PO₄(P₂O₃ + 3H₂O - 2H₂PO₃), and also the hypothetical anhydride of H₂PO₄(P₂O₄ + 2H₂O - H₂PO₄O₃); P₂O₄ is the hypothetical anhydride of H₂PO₄(P₂O₄ + 2H₂O - H₂PO₄O₃), but this oxide gives H₂PO₃Aq and H₂PO₄Aq with wates (a. Phosphorus Tetroxide, p. 141). The oxyacids of P do not correspond in composition with those of N (v. Table in Nitrocen group of Elements, vol. iii. p. 575).

HYPOPHOSPHOROUS ACID AND SALTS II, PO,; MIL, PO, and MI(H, PO),. Hypophosphites are formed by decomposing phosphide of Ba, Ca, or Sr by water (Dulong, A. Ch. [2] 2, 141); by heating P with potash, milk of lime, or BaOAq (II. Rose, P. 9, 226, 361; 12, 77, 288); by passing PH, into solution of alkalis or alkaline hydrates (Wingkler, P. 11, 443); and by heating P with syrupy H, PO, Aq to 200° (Oppenheim, Bl. [2] 1, 163). The acid is monohasic; it may be regarded as derived from the hypothetical anhydride P₂O. There is no acid, nor are there salts, corresponding with hyponitrous acid II NO, but some salts are known of the form MPS; v. Thiometahypophosphites, at beginning of Phosphorus, sulphides of (p. 146). Sclenometahypophosphites MPSe have also been isolated (v. Diphosphorus sellenide, p. 144).

HYPOPHOSPHORUS ACID H.PO. Melts at 17.4° (Thomsen, B. 7, 994; ? specimen pure). H.F. [H²,P,O²]=139,970 (production of crystallised

said); 187,660 (production of said in liquid state); [H²,P,O²,Aq]=189,800 (Th. 2, 225).

Preparation.—Ba(H,PO₂),H₂O is prepared by warming water with BaO and P (in small state).

pieces) in a basin till inflammable P hydride cesses to come off, filtering, removing excess of BaO by passing in CO₂, filtering again, and crystallising. 285 g. pure Ba(H₂PO₂).H₂O are dissolved in c. 5 litres water, 98 g. H₂SO₄ (c. 1015 g. ordinary conc. acid), diluted with 3 to 4 times its weight of water, are added; after shaking for some time the pp. of BaSO, is allowed to settle, and the clear liquid is syphoned off, and evaporated in a porcelain dish, by boiling, till it is c. 10 of the original volume, when it is placed in a Pt dish; a thermometer is immersed in the liquid, evaporation is continued, the temperature being allowed to rise gradually to 110°; any solid which separates is filtered off while the liquid is hot, and the filtrate is evaporated, without being allowed to boil, at c. 110°. Thom-sen (B. 7, 994) finally heats for 10 mins. to 130° or 138°, filters into r. stoppered bottle, and cools below 0°; Geuther a. Ponndorff (J. Z. 10, Supplbd. 2, 45, 49) say that heating above 110° decomposes H,PO, and that Thomsen's preparation therefore contained HaPOs.

Properties .- Large, white, crystalline tablets; melting at 17.4°; remains liquid considerably above m.p. (Thomsen, l.c.). Decomposed by heat to PH, and H,PO. H,PO.Aq is a very energetic reducing agent. The acid is monobasic, forming

Reactions.—1. Decomposed by heat, giving P hydride and H₂PO₄ (H. Rose, l.c.).—2. H₂PO₂Aq is readily changed to H₃PO₃Aq or H₂PO₄Aq by oxidisers; Cl. Br. HNO₃Aq. KMnO₄Aq. and several metallicoxides produce H₃PO₄Aq (Dulong, Lc.; Rose, Lc.; P. de St. Gilles, A. Ch. [3] 55,374); PbO₂ forms PbHPO₄ (Wurtz, C. R. 18, 702); SO₂ forms H₄PO₄Aq and S (Geuther a. Ponndorff, l.c.). According to Engel (C. R. 110, 786) Pd charged with H oxidises H₄PO₄Aq to H₃PO₃Aq with evolution of H .- 3. HaPO Aq reduces solutions of salts of gold, silver, and mercury, ppg. the metals; of gold, sever, and mercury, ppg. the retais; from copper sulphate solution, Cu,H, is ppd. at 55°-60° (Wurtz, l.c.; Rammelsberg, l.c.).—4. Reduced by nascent hydrogen to PH, (Dusart, C. R. 43, 1126; Blondlot, C. R. 52, 1197).—5. With hydrodic acid forms PH, I (G. a. P., 120). l.c.) .- 6. Heated with conc. sulphuric acid, H.PO., SO., and S are produced (Wurtz, l.c.). 7. Heated with phosphorus pentachloride, POCl, PCl, and HCl are formed; phosphorus trichloride produces P, H,PO, and HCl; with phosphoryl chloride, P, PCl, HPO, and HCl are the products (Geuther, $J_{\bullet}pr$. [2] 8, 359).

HYPOPHOSPHITES M'H,PO, and M"(H,PO,), These salts are formed in several reactions (v. beginning of this article); the greater number are prepared by reacting on the salt of Ba with the sulphates of other metals; the salts of Ba, Ca, and Sr are generally prepared by heating BaOAq, CaOAq, and SrOAq with P. The hypo-phosphites of Cd, Ca, Pb, and Tl crystallise without water; those of Ba, Li, Mn, Na, Sr, and U with one H.O; those of Co, Mg, Ni, and Zn with 6H,O (Rammelsberg, C. J. [2] 11, 12). They are decomposed by heat, evolving P hydride and H, and generally leaving pyro- and meta- phosphate, the Co and Ni salts leave metaphosphate

and phosphide, and the U salt leaves pyro- and meta- phosphate and phosphide (R., l.c.). The hypophosphites are easily oxidised to phosphites and phosphates, hence they react as reducing agents. Heated in solution with alkalis they agents. Heated in solution with Birkhils Lieg give phosphites, and then phosphates, and evolve H (Wurtz; H. Rose, l.c.). The chief memoirs on hypophosphites are by H. Rose (P. 9, 225, 361; 12, 77, 288); Wurtz (A. Ch. [3] 7, 193; 16, 196); and Rammelsberg (C. J. [2] 11, 1, 13).

Ammonium hypophosphite NH, H, PO2. Hexagonal tablets; by decomposing the Ba salt by (NH₄), SO, Aq; easily sol, absolute alcohol (Wurtz.

Rose).

Barium hypophosphite Ba(H2PO2), H2O. Lustrous monoclinic needles (Rammelsberg; Topsöe, W. A. B. 69 [2] 19). By heating BaOAq with P till gas ceases to come off, filtering, removing BaO from the filtrate by CO, filtering, and crystallising. Loses HO at 100°. Soluble in 31 parts cold, and 3 parts boiling, water; insol. alcohol. Heated out of air leaves pyro- and meta- phosphate (Wurtz, Rose, Rammelsberg).

Calcium hypophosphite Ca(H₂PO₂). Prepared like the Ba salt. Berlandt (Ar. Ph. [2] 122, 237) recommends 29 parts P, 47 parts CaO,H, and 24 parts water. Bachmann and Martenson (J. 1864. 191) decompose Ca phosphide by boiling water. Thin, monoclinic tablets (Rammelsberg; Schabus, J. 1854. 325). Very bitter taste; unchanged in air; does not give off H₂O at 300°; heated to redness gives off H, PH₃, and H₂O, and leaves pyro- and meta- phosphate (Rammelsberg; Michaelis, J. 1872. 210). Sol. 6 parts cold water, not much more sol. hot water; insol. strong alcohol (Rose).

Cobalt hypophosphite Co(H.PO2)2.6H2O. Red octahedral crystals, isomorphous with Mg salt (Rose); by decomposing Ba salt by CoSO,Aq, filtering, and evaporating in vacuo (Wurtz). Forms a double salt with Ca(H,PO2)2 (Rose).

Comer himonhosphite Cu(H,PO2)2. Obtained

Copper hypophosphite Cu(H_PO₃). Obtained with difficulty from Ba salt and CuSO, Aq; solution easily decomposes, giving Cu_H₂ (Wurtz).

Lead hypophosphite Pb(H₂PO₃). By adding PbO or PbCO₄ to H₂PO₂Aq (Rose, Wurtz).

Manganese hypophosphite Mn(H,PO,), H,O Small, rose-red crystals; from Ba salt and MnSO Aq (Wurtz, Rammelsberg); or by boiling

Ca salt with Mn oxalate (Rose).

Potassium hypophosphite KH,PO, Prepared by decomposing the Ba or Ca salt by K,CO,Aq, filtering, evaporating to dryness, treating the residue with alcohol, and crystallising the alcoholic solution in vacuo; or by dissolving P in boiling KOHAq, evaporating, and dissolving out from the residue by alcohol; also by decomposing the Basalt by K.SO.Aq (Rose, Wurtz). A white, semi-crystalline mass. Easily sol. water and alcohol; very hygroscopic (Dulong, A. Ch. [2] 2, 141). Burns when heated in air; oxidised violently by evaporation with HNO.Aq. Heated out of air evolves inflammable P hydride, and leaves pyro- and meta- phosphate (Rammelsberg).

Sodium hypophosphite NaH_PO_.H_O. Pre-pared like the K salt. Small, rectangular tablets, easily sol. water and absolute alcohol. Evaporation of the solution is attended with explosions (Marquart, Ar. Ph. [2] 95, 284; Trommsdorff,

ibid. 99, 888).

The salts LiH.PO.H.O. Ni(H.PO.M6H.O.

Sr(H₂PO₂)₂, and Zn(H₂PO₂), are also described; and salts of Al, Be, Cd, Or, and Fe have been obtained, but their compositions are somewhat doubtful.

PHOSPHOROUS ACID AND SALTS H.PO,; M'H.PO, M',HPO, M',HPO, M''HPO,, M''HPO,, M''',(HPO,), P₂O, is the anhydride of H,PO,; the acid is produced by dissolving the oxide in cold water, but the oxide is not obtained by removing H.O from the acid. H.PO, is dibasic; the salt Na,PO, said to be formed by adding a large excess of NaOH to H,PO, (Zimmermann), has been shown by Amat (C. R. 108, 403) not to exist. The acid is formed by oxidising P slowly in moist air; the salts are obtained by reactions between the acid and metallic hydroxides, or by double decomposition from the alkali salts. Neither the acid nor salts of the acid corresponding with nitrous acid, HNO₂, are known, nor have thio-salts of this form been isolated.

PHOSPHOROUS ACID H₃PO₃. Melts at 74° (Geuther a. Hurtzig, A. 111, 159); at 70·1° (Thomsen, J. pr. [2] 8, 359). H.F. [H³,P,O³] = 227,700 (crystallised acid); 224,630 (acid in liquid state); 227,570 (acid in aqueous solution) (Th. 2, 225). Heat of fusion = -3070; one gram-molecule of the liquid acid occupies 49.66 c.c. (Th. 2, 224).

Formation. -1. Along with H, PO, and H, PO, by the long-continued oxidation of P in moist air (v. J. Corne, J. Ph. [5] 6, 123).—2. By dissolving P in dilute HNO₃Aq and allowing to oxidise in air.—3. By the oxidation of H₂PO₂Aq by weak oxidisers.—4. By dissolving P₂O₂ in cold water (Thorpe a. Tutton, C. J. 57, 567).—5. By decomposing PCl, by ILO, or by warming with H.C.O. (Hurtzig a. Gouther, A. 111, 159); or by leading Cl into warm water in presence of an excess of molten P (Droquet, P. 12, 628).

Preparation .- 1. A small quantity of PCl, is shaken with cold water, the reaction is moderated by plunging the beaker into cold water; when the PCl, is all decomposed, a little more is added, and so on (PCl₂ + 3H₂O + Aq = 3HClAq + H₃PO₃Aq). The solution is evaporated, the temperature being raised to 180° near the end of the process; the syrupy liquid thus obtained is placed over H₂SO₄, in vacuo, till it crystallises; addition of a crystal of H₂PO₄ causes rapid crystallisation (Thomson, B. 7, 996). 2. A stream of dry air is passed through PCl, at 60°, and then into two flasks, each containing c. 100 g. water at 0°; after c. 4 hours the first flask is filled with crystals, which are drained under a pump, washed with small quantities of ice cold water, and dried in vacuo (Grosheintz, Bl. [2] 27, 433).—3. A mixture of 1 part PCl, and 2 parts dry H₂C₂O₄ is heated in a flask with a reversed condenser until a clear liquid is obtained; the liquid is evaporated in a stream of CO., and the crystals are washed and dried as in 2 (Hurtzig a. Geuther, A. 111, 159: PCl₂+3H₂C₂O₄ = H₂PO₂+3CO+3CO₂+3HCl).

Properties. A colourless, crystalline mass; obtained in transparent crystals by evaporating H,PO,Aq in vacuo over H,SO, Melts at 74° (H. a. G., l.c.); at 701° (Thomsen, l.c.). Heated above its m.p. decomposes to H.PO, and PH₁. H₂PO, is very deliquescent, and oxidises very slowly in air; it acts as an energetic reducing

agent. H,PO, is dibasic, forming salts M'H,PO, and M, HPO.

Reactions .- 1. Heated above its m.p., H.PO. decomposes to H.PO, and inflammable P hydride (Vigier, Bl. [2] 11, 125; Rose, Davy, Gm. K. 2, 115); according to Hurtzig a. Geuther (A. 111, 159) Palso separates. -2. Slowly oxidised in air to H.PO.; dilute solutions of H.PO. are more rapidly oxidised; according to Salzer (A. 232, 114), H,PO,Aq does not oxidise in air at ordinary temperatures. - 8. Converted into H.PO, by many oxidisers, e.g. HNO, Aq, OlAq, BrAq, KMnO, Aq, hypochlorites; with SO, Aq, H.PO, Aq and H.S are formed along with S (Gm.-K. 2, 116).-4. Reduces many metallic salts in solution; e.g. AgNO₃Aq to Aq, HgClAq to HgCl and then to Hg, CuClAq to Cu,O₃ and then to Cu (Rammelsberg, C. J. [2] 11, 13).—5. Nasto de (Raininesberg, C. 2, 12) 11, 15, 35, 35, 36, 48, 1126). 6. When crystalline H₂PO₄ is heated with bromine to 100° in a sealed tube, H₂PO₄ is former along with HBr and PBr_B, or the products are HPO, and HBr, according to the relative quantity of Br used (Gustavson, J. 1867, 139). According to Ordinaire (C. R. 64, 863), a crystalline compound is obtained -perhaps bromo-phosphorous acid—by heating H,PO, and Br in the ratio H.PO.: 4Br.—7. By heating H.PO. with iodine Gustavson (l.c.) obtained H.PO., HI, PI., and PII, I.—8. Heated with phosphorus trichloride to 170°, P. HCl, and H.PO, or H.P.O, are formed (Geuther, J. pr. [2] 8, 859; Kraut, A. 158, 882; Gautier, C. R. 76, 49). At 70° HCl, H.P.O, and a compound PHO are formed, according to Gautier (l.c.) (v. Phosphorus, compounds of, with HYDROGEN AND OXYGEN, p. 134).—9. With phosphorus pentachloride, POCla HCl, and PCl are produced; and the products of the reaction with phosphoryl chloride are POl, HPO, and HOI (Geuther, J. pr. [2] 8, 359).—10. By neutralisation with alkalis or alkaline carbonates salts of the form M.HPO, are produced.

Qualitative distinction between phosphorous and hypophosphorous acids. H₂PO₂Aq reduces

CuSO, Aq to Cu, while the reduction product with H,PO,Aq is Cu,H,.
PHOSPHITES M'H,PO,, M'2HPO,, M"HPO,,
M"12(HPO,), These salts are generally obtained by neutralising H, PO, Aq by metallic hydroxides or carbonates, or by double decomposition from the alkali salts. They are also formed by the slow oxidation of hypophosphites. Zimmermann's assertion that Na, PO, exists (A. 175, 1) has been disproved by Amat (C. R. 106, 1851), who has shown that the normal Na salt is Na_HPO_s. The alkali phosphites are soluble water; most of the others are insoluble. Phosphites are decomposed by heat, generally giving off H or PH,, and leaving pyrophosphate and phosphide. Solutions of phosphites are scarcely changed in air, but they are readily oxidised to phosphates by energetic oxidisers. The chief memoirs on phosphites are those of H. Rose (P 9, 26, 224; 12, 77, 258), Rammelsberg (P. 181, 263, 359; 132, 481; B. 9, 1577), Kraut (A. 177 274), Wurtz (A. 58, 65).

Ammonium phosphites (NH.)H.PO, and (NH.).HPO, 2H.O. The former is obtained by adding NH, Aq to H, PO, Aq till neutral to methyl orange, concentrating, and drying the crystals over H₂SO₄; melts 128°; above 150° gives off

NH, and PH,, and leaves H,PO,; absorbs NH, at 80°-100°, forming (NH,),HPO, (Amat, C. R. 105, 80°). The salt (NH,),HPO,2H,O was obtained by Rose by adding slight excess NH,Aq then at 150° (A., La.). The acid salt to the acid and crystallising; in vacuo at ordinary temperature, or at 100° in air, loses NH, and gives NH, H,PO, (Amat, l.c.).

and gives NH₂H₂PO₅ (Amat, l.c.).

Barium phosphites. The normal salt
BaHPO₅ is obtained by adding BaCl₂Aq to
(NH₃).HPO₅Aq (Berzelius, Gm. K. 2, 270), also
by boiling BaHPO₅Aq with KOHAq. A crystalline powder; strongly heated gives Ba₂P₂O₅, H,
and Ba phosphide (v. Hamfinelsberg, B. 9,
1577); very slightly sol. water; on boiling
with water gives a basic and an acid salt
(Dulong, Gm.-K. 2. 270). The acid salts
(Dulong, All₂PO₅, 2H₂O are said to be formed by
the action of H₂PO₅Aq on the normal salt the action of H_aPO_aAq on the normal salt (Rammelsberg, Rose, Wurtz).

Calcium phosphites. CaHPO₃,xH₆O; from CaCl₂Aq and (NH₃,HFO₂Aq (Wurtz, Rose, Rammelsberg). The acid sait CaH₂(HPO₃)₂,H₆O is obtained by dissolving marble in H₂PO₃Aq,

and evaporating in vacuo (Wurtz).

Cobalt phosphite CoHPO, 2H.O. powder, obtained by CoCl,Aq+(NH,),HPO,Aq, or by dissolving freshly ppd. CoCO, in H,PO,Aq; goes blue at 250° (Rose, Rammelsberg).

Copper phosphite CuHPO3.2H2O. By double decomposition from (NH₄), HPO₃ (Rose); also by acting on Cu acetate by H₃PO₃Aq (Wurtz). Un-

acting on Cu acetate by H₂PO₂Aq (Wurtz). Unchanged by boiling water (Rammelsberg), but reduced to Cu by boiling with H₂PO₂Aq (Rose). Lead phosphiles. The normal salt PbHPO₃ is obtained by ppg. Pb acetate by (NH₄)₂HPO₂Aq (Rose). A white powder; heated gives off H and PH₃, leaving Pb₂PO₃ and Pb phosphide. Insol water (Amat, C. E. 110, 901). By adding NaH₂PO₃Aq to excess of Pb2NO₃Aq, the compound PbHPO₃Pb(NO₃), is obtained (Amat, l.c.). The acid salt PbH₂(HPO₃)₂ is formed by dissolving the normal salt in very cone. H₂PO₂Aq, and drying the crystals at 100°; with water gives PbHPO₃ and H₃PO₃Aq (Amat, with water gives PbHPO₃ and H₃PO₃Aq (Amat) with water gives PbHPO, and H,PO,Aq (Amat,

Le.).

Magnesium phosphite MgHPO,xH.O. By
DDR. boiling MgSO,Aq by Na.HPO,Aq

MgSO,Aq by Na.HPO,Aq

Agailla salt (Rammelsberg). Forms a double salt Mgs(NH₄)₂(HPO₃), 16H₂O (Rammelsberg, Rose), Manganese phosphite MnHPO₂, H₂O. A red-

dish, powder; very slightly sol. water, more sol. solutions of Mn salts; loses H₂O at 200°. From NH, salt and a Mn salt; or by dissolving MnCO, in H,PO,Aq, and adding Na,CO, till ppn. begins, but not enough to remove acid reaction (Rose, Rammelsberg).

Potassius phosphites. The normal salt K.HPO, is formed from H.PO, Aq and KOHAq A.H.P. 18 formed from H. P. V. Aq and K. OH. Aq r. K. O. Aq; semi-crystalline, syrup-like mass; very hygroscopic; insol. alcohol (Wurtz, Rose). The acid salt K. H.P. O. 2H. P. O. was obtained by Wurtz (A. 58, 63). Amat (C. R. 106, 1351) obtained the acid salt K. H. P. O. by adding KOHAq ore K. C. O. Aq to H. P. O. Aq till neutral to

methyl orange, concentrating, and cooling.

Sodium phosphites. The normal salt
Na,HPO,-5H,O is obtained by dissolving H,PO, in an excess of NaOHAq, and evaporating in vocuo (Amat, C. R. 108, 403). Zimmermann (4. 175, 1) supposed that Na,PO, is formed

heat of solution at $18.5^{\circ} = -4600$ (Amat, C. R 110, 191). Debydrated by drying in vacuo, and then at 150° (A., l.c.). The acid salt 2NaH,PO,5H,O is produced by making H₃PO₄Aq neutral to methyl orange by NaOHAq The property of the property 106, 1351).

Zinc phosphite 2ZnHPO, 5H,0; from ZnSO,Aq and ammoniacal solution of PCl, (Rose); also from PCl,Aq and ZnO (Rammela-

The following phosphites have also been described:—Di₂(HPO₃)₃ (Frerichs a. Smith, A. 191, 331); Fe₂(HPO₃)₃, 9H₂O (Rose, Rammelsberg); La₂(HPO₃), (F. a. S., L.c.); SnHPO₃ (Rose). Phosphites of Al, Be, Bi, Cd, Cr, ferman rous Fe, Hg, Ni, and Sr have also been prepared, but their compositions are somewhat doubtful (v. especially Rose, l.c.)

(9. cspecially rose, i.e.).

HYPOPHOSPHORIC ACID AND SALTS

H₁P₂O₀, M'H₂P₂O₀, M'₂H₂P₂O₀,

M'₄P₂O₀, M'H₂P₂O₀, M''₂P₂O₀. When sticks of

P are partly covered with water and left for some time in a large vessel, an acid liquid is obtained; this liquid was formerly called Pelletier's phosphatic acid (P., Crell. Ann. 1796 [2] 447). Dulong (A. Ch. [2] 2, 141) found 478 p.c. P and 52-2 p.c. O in this substance, and supposed it to be P₂O₉. In 1856 Pagel (J. pr. 69, 24) showed that the acid liquid contained phosphoric and phosphorous acids; and in 1877 Salzer (A. 187, 322) proved the presence of small quantiities of a new acid to which he gave the composition nH_2PO_1 and the name hypophosphoric acid. The acid has been found to be tetrabasic, hence the formula is written H₄P₂O₆. The hypophosphates are generally formed directly from the acid, or by double decomposition from the alkali salts. The hypophosphates are more stable than the hypophosphites and phosphites; normal salts pass into phosphates by taking up O; they are decomposed by heating strongly giving of PH3 or H, and leaving phosphate and phosphide.

Hypophosphoric acid H,P.O. Melts at c. 55° (Joly, C. R. 102, 110). Heat of solution = 3,850 (J., l.c.).

Formation.—1. Along with H₂PO₃ and H₃PO₄, by the slow oxidation of P in moist air (Salzer, A. 187, 322; 194, 28; 211, 1; 232, 114. 271).-2. The Ag salt is formed by oxidising P by dilute HNO, Aq in presence of AgNO, (Philipp. B. 18, 749); also by reacting on H₃PO₃Aq with AgNO₃Aq (Sänger, A. 232, 1); and the Cu salt by reacting on P with Cu(NO3)2Aq (Corne, J. Ph. [5] 6, 123).

Preparation .- Sticks of P are placed in glass tubes narrowed at the lower end; these are arranged inside a funnel, which is placed in the mouth of a bottle containing a little water; the bottle is set in a basin, and the whole is covered with a large bell-jar open at the top. The apparatus is placed in a cool place (best in In a apparatus is piaced in a cool piace (local in a cellar) for some weeks or months; according to Joly (C. R. 101, 1958), from $\frac{1}{2}$ to $\frac{1}{2}$ of the P is oxidised to $H_1P_2O_8$ if the process is conducted in winter, and not more than $\frac{1}{10}$ in sammer.

The sold liquid is mixed with a cold cone. solution of Na scetate, the ppd. Na,H,P,O,.6H,O is collected, washed with a very little cold water, then dissolved in water (sol. in c. 45 parts cold water), and ppd. by Pb acetate; the Pb,P,O, is collected, washed with cold water, suspended in water, and decomposed by H,S; the filtrate is evaporated at a low temperature-not exceeding -or in vacuo over H.SO, until crystals of H,P2O4 are deposited. Joly (C. R. 101, 1058, 1148) heats to boiling the acid liquid obtained by oxidising P, as described above, adds Na CO, till nearly neutral to methyl orange, and crystallises by concentration; he washes the crystals of Na₂H₂P₂O₈.6H₂O with cold water, and recrystallises from hot water, dissolves in hot water, adds an equivalent of BaCl, in hot water, washes the ppd. BaH₂P₂O₆, decomposes it by an equivalent of H₂SO₁ diluted with its own weight of water, filters after two or three days, and evaporates in vacuo over H.SO. Drawe (B. 21, 3401) carries out the oxidation of P in presence of Na acetate solution.

Properties .- Small colourless crystals, which melt at c. 55° (Joly, C. R. 102, 110); very hygroscopic; solution is unchanged in air at ordinary temperatures. Heated to c. 70° suddenly decomposes to H₃PO₃ and HPO₃ (J., l.c.); at c. 120° gives H₄P₂O₇ and P hydride (J., C. R. 102, 760).

Reactions and Combination .- 1. Heat decomposes H₄P₂O₆ (v. supra).—2. Not oxidised by such oxidisers as H₂O₂Aq, ClAq, CrO₃Aq, HgCl₂Aq, &c .- 3. Not reduced by such reducers as SO, Aq. H2S, or Zn and H2SO, Aq. -4. Potassium per manganate is slowly reduced in the cold, quickly on heating, by H₁P₂O₂Aq to which H₂SO₄Aq has been added.—5. Heated with nitric acid, HaPO, Aq is formed .- 6. Heated with dilute sulphuric acid, H,PO,Aq and H,PO,Ag are produced.—7. Silver nitrate solution gives a white pp., which does not blacken in light and is soluble in warm HNO Aq (1:1). 8. By evaporating H.P.O. Aq till the liquid had the composition P.O. ill.O, and then placing over H.SO. in wacuo, Joly (C. R. 101, 1058; 102, 110) obtained crystals of the hydrate H,P,O,2H,O, melting at 62°-62.5°.

salts have been examined chiefly by Salzer (A. 187, 322; 194, 28; 211,1; 232, 114, 271), and crystallographically by Haushofer a. Fresenius (Z. K. 1, 257, 620; 3, 605; 6, 113; 9, 254). The hypophosphates are much more stable towards oxidisers than the hypophosphites or phosphites. They reduce KMnO, Aq very slowly in the cold after addition of H.SO Ag, and give white pp. with AgNO, Aq unchanged in light.

Ammonium hypophosphates. The normal salt (NH₁), P.O., xH₂O is obtained by adding excess of NH₃Aq to the acid; on drying, loses NH₃ and effloresces. The acid salts NH, and efforesces. The acid salts (NH,)₂H₂P₂O₄ and (NH₄)₃HP₄O₅ are formed, the former by boiling a solution of the normal salt, the latter by adding the proper quantity of H.P.O. to the former salt.

Barium hypophosphates. The normal salt Ba,P,O is obtained from BaCl,Aq and Na,P,O,Aq; the acid salt BnH,P,O,2H,O is formed from NaH,P,O,Aq and BaCl,Aq (v. Joly, C. R. 101, 1058).

Cadmium hypophosphate Cd.P.O. 2H.O; and the double salt CdNa.P.O. 6H.O (Drawe, B. 21, 3401).

hypophosphates Ca2P.O. Calcium CaH.P.O. 6H.O.

Cobalt hypophosphate Co.P.O.8H.O; and the double salt 2CoNa.P.O.3H.O (Drawe, l.c.). Copper hypophosphate Cu,P2O.6H2O (Drawe,

Lead hypophosphate Pb_P_O. Magnesium hipophosphates Mg_P_O.12H_O and MgH_P_O.4H_O; and the double salt

Mg(NI₁),P₂O₆OI₂O.

Nickel hypophosphate Ni,P₂O₆12H₂O; and the double salt NiNa, P.O., 12H,O (Drawe,

Potassium hypophosphates K₄P₂O₆.8H₂O, K₂HP₂O₆.3H₂O, K₂H₂P₃O₆, and KH₃P₂O₆.

Silver hypophosphate Ag.P.O. (v. Philipp, B. 14, 749).

Sodium hypophosphates. The acid salt Na₂H₂P₂O₃.6H₂O is obtained by slowly oxidising P in moist air, and adding Na acctate solution as described under Preparation of hypophosphoric acid (p. 154); sol. 45 parts cold, or 5 parts boiling, water; insol. alcohol; on strongly heating gives off H and P hydride and leaves NaPO₃. The normal salt Na,P₂O₆:10H₂O is obtained by adding an equivalent of Na_CO₃ to Na_H_P_O₄Aq; sol. c. 30 parts cold water, much more sol. hot water; solution reacts alkaline, and gives a mixture of salts on evaporation. The acid salt Na, HP, O, 9H, O is formed by mixing the Na, and Na, salts in the ratio Na, H.P.O. : Na, P.O. The acid salt NaH.P.O. : 2H.O is formed by adding the proper quantity of H₁P₂O₆Aq to Na₂H₂P₂O₆. For reaction of the Na salts with different indicators v. Joly, C. R. 101, 1058.

Another acid salt Na, H, (P,O,). 20H,O is said to be formed by adding rather more than one molecular weight NaOH to 4Na₂H₂P₂O₆.6Π₂O.

Zinc hypophosphate Zn.P.O. 2II.O (Drawe,

PYROPHOSPHITES. In 1887 Amat (C. R. 106, 1400) showed that when 2NaH2PO35H2O is heated to 160° it loses 6H O and gives the salt Na₂H₂P₂O₃. A few other salts of the form M.H.P.O. have been obtained, but the acid has not been isolated. When the Ba salt is decomposed by an equivalent of H.SO.Aq, the solution shows the reactions of pyrophosphites, but the pyrophosphite gradually changes to phosphite (Amat, C. R. 108, 1056). The pyrophosphites in solution slowly change to phosphites, the more rapidly the more cone. the solution and the higher the temperature; the presence of an acid, e.g. H.SO, greatly quickens the rate of change (A., l.c.). Addition of NaOHAq to a boiling solution of the Na salt produces Na₂HPO₂ (A., C. R. 106, 1400). Pyrophosphites in very dilute solutions give no pp. with Ph(NO₃)2Aq until boiled; phosphites give an immediate white pp.; this reaction serves as a qualitative test for the two classes of salts (A., C. R. 110, 901).

Lead pyrophosphite PbH.P.O. is obtained by heating PbH (HPO), in a lry vacuum to c. 140

It is insol. water, but is gradually changed by water to H₂PO₂Aq and PbHPO₂ (A., C. R. 110, 901).

Sodium pyrophosphits Na,H,P,O, is formed by heating 2NaH,PO,.5H,O, which has been partially dehydrated in vacuo, to c. 160°. V. sol. water; solution changes to NaH,PO,Aq, but by careful evaporation in vacuo over H,SO, crystals of Na,H,P,O, can be again obtained (A., C. R. 108, 1056). Presence of acid hastens the change to NaH,PO,Aq; this change is also effected by adding NaOHAq to boiling Na,H,P,O,Aq. Heat of solution of Na,H,P,O,3 = 300 (A., C. R. 110, 191).

For thiopyrophosphites M,P,S, and thio-oxypyrophosphites M,P,O,S, and M,P,O,S v. Phosphosous sulphide, Reactions 7 and 8, p. 146; and for selenopyrophosphites M,P,Se, v. Phosphosous selenide, p. 145). M. M. P. M.

PHOSPHORYL COMPOUNDS. Compounds of the radicle PO are generally called hosphoryl compounds; and compounds of the radicle PS are often called this phosphoryl compounds. These compounds are described in this Dictionary as phosphorus caychloride, oxylfuoride, sulphochloride, &c. The phosphoryl compounds are PO(NH₂), POCl, POBr, POBrCl, and POBr,Cl, POF, FO.NH.NH., PON. The thiophosphoryl compounds are PS(NH₂), PSCl, PSBr, PSBrCl, PSF, The compounds P,O,Cl, and P,S,Br₂, are sometimes called pyrophosphoryl chloride and pyrothiophosphoryl bromide, respectively.

(a)-PHOSPHOTOLUIC ACID M. M. P. M.

C_sH_sMe(PO_sH_s).CO_sH [3:4:1]. Toluphosphinic acid. [262⁵]. Formed by oxidising m-xyleno phosphonic acid with hot alkaline KMnO_s (Weller, B. 20, 1723; 21, 1492). Prisms, v. sol. hot water, v. e. sol. alcohol. Yields HPO_s and m-toluic acid when heated.—PCl, yields oily C_sH_sMe(POCl_s).COCl.—PbHA''' aq: needles (from dilute HOAc).—Ag_sA'''.

(β)-Phosphotoluic acid

C₄H,Me(PO,H₂).CO₂H [5:3:1]. [220°]. Formed by oxidising s-m-xylene phosphonic acid (Weller). Yields HPO, and m-toluic acid on heating.—Ag₂A": amorphous pp.

PHOTO-CHEMISTRY v. Influence of light on chemical change, under Chemical Change, vol. i. p. 748; also next article (Photographic Chemistry); also Optical methods, a section of Physical methods, in this volume, p. 221.

PHOTOGRAPHIC OHEMISTRY. The photographic processes at present in use depend primarily upon the photo-chemical decomposition of certain metallic compounds in the presence of suitable oxidisable substances known as sensitisers. Broadly speaking, the photodecomposable compound may be regarded from a chemical point of view as an oxidising agent, of which the oxidising power is only brought

into action under the stimulus of light, the associated compound or sensitiser being at the same time oxidised by the oxygen or haloger thus liberated. Very many metallic compounds are thus susceptible to the influence of light although only a few of these have up to the present time found practical application. The nature of the chemical change undergone in such cases may be well illustrated by the action of light upon ferric salts. An aqueous solution of ferric chloride, for example, is not acted upon by light because the associated substance (water) is not capable of reacting with the liberated chlorine with sufficient rapidity; in other words, water is incapable of acting as a sensitiser towards ferric chloride. But if some oxidisable organic compound is present, light then reduces the ferric to the ferrous salt. Thus an alcoholic solution of ferric chloride exposed for a few minutes to sunlight gives a blue colouration with potassium ferricyanide, indicating the presence of a ferrous salt, rockelly formed according to the equation probably formed according to the equation Fe, Cl_s + C, H_oO = Fe, Cl_s + C, H_oO + 2HCl. In a similar way paper coated with a solution of ferric chloride can be used to obtain prints, because the paper (or the size contained in it) plays the part of a sensitiser, and the exposed portions of the surface thus become covered with a ferrous instead of a ferric compound, and on brushing over with a solution of ferricyanide the print is developed in blue. In practice ferric oxalate is found to be the most sensitive ferric compound. the organic acid being the sensitiser : Fe2(C2O4)3

= Fc₂(C₂O₄)₂ + 2CO₂.

Although the chemical action of light upon metallic compounds generally is of the nature of reduction, and is accompanied by the simultane, ous oxidation of the compound which plays the part of a sensitiser, there are many instances in which light promotes the action of atmospheric oxygen or other oxidising agent. Thus potassium iodide may be kept in a dry atmosphere in the dark for any length of time without undergoing change, but in the presence of light and moisture photo-chemical oxidation takes place,

and the salt becomes alkaline:

 $4KI + 2H_2O + O_2 = 4KOH + 2I_{2*}$ Action of light upon silver salts. Of all known metallic compounds the salts of silver are the most sensitive to the action of light, and these salts accordingly form the basis of all existing photographic processes. The most familiar instance of the photo-decomposition of a silver salt is the well-known change in colour experienced by silver chloride on exposure to light, a phenomenon which has been familiar since the sixteenth century. The other silver haloids, viz. the bromide and iodide, are also decomposed by light, the latter only in the presence of some sensitiser capable of rapidly absorbing iodine. The absolute sensitiveness of the silver haloids cannot be estimated by the degree of darkening on exposure, because the product of photo-decomposition is of a darker colour in the case of the chleride than in the case of the bromide, and the product is darker in the case of the bromide than in that of the iodide. The sensitiveness is actually determined by two conditions, viz. the nature of the sensitiser and the state of molecular aggregation of the silver haloid. In most of the negative processes

ow in use, the bromide or iodide, or a mixture t the two, forms the sensitive surface.

The nature of the chemical change undergone n exposure to light has not yet been completely lucidated for all the silver haloids. It is known hat the chloride loses chlorine on exposure, and hat the darkened product contains less chlorine han the unaltered haloid. It is as yet uncerain whether the halogen which is given off is lways evolved in the free state or not; it has been hown, however, that silver chloride on exposure o light gives off a gas which rapidly turns potasium iodide and starch paper bine (Meldola, hemistry of Photography, p. 66). It is stated y many writers that the darkened product is a whehloride formed according to the equation:
AgCl = 2Ag₂Cl + Cl₂. There is, however, no satisactory evidence of the existence of such a subalt, and it seems more probable that the dark roduct consists of an oxychloride, in combinaion, or admixture, with unaltered chloride. Acording to some analyses by Hodgkinson, the xychloride has the formula Ag OCl2. In support if this conclusion it is found that the chloride loes not darken in absolutely dry air, unless apour of mercury is present (Abney), thus naking it appear that moisture is essential for he decomposition. The latest investigation of he action of light on AgCl by Baker (C. J. 61, '28) confirms the view that the darkened product ontains an oxychloride; Baker gives the formula lg₂ClO. A second, white, oxychloride also robably exists (Richardson, C. J. 59, 536). Silver chloride is thus analogous to cuprous or hallous chloride, which also darken under the nfluence of light, with the formation of what are believed to be oxychlorides. Whatever may se the chemical composition of the darkened product, it is probable that the bromide and iodide rive rise to the formation of analogous com-ounds, and that the invisible picture in the older processes is formed of these products on The unbackground of unaltered haloid. leveloped image on modern dry plates, coated with gelatin emulsion, may, however, have a diferent composition, owing to the presence of the organic sensitiser.

Photosalts of silver. These are coloured forms of the silver haloids prepared by the action of certain reducing agents upon silver compounds, and the subsequent conversion of the partially reduced products into the haloids by treatment with the necessary acids. These compounds are of a red or purple colour, and have been shown to contain less halogen than the unaltered haloids. It is probable that they consist of physical combinations of the oxyhaloid or hydrated oxyhaloid with the unaltered haloid; their discoverer (Carey Lea) has shown that they closely resemble, if they are not actually identical with, the products of the photo-chemisal reduction of the sliver haloids. If this be admitted, it follows that the product which forms the photographic image can be prepared

by purely chemical methods (Am. S. 1887). Photographic processes. In all photographic processes the first operation is the exposure of a surface coated with a uniform film of the silver haloid to the image formed by a lens in a camera. The image thus depicted on the film

slight difference in colour between the product of photo-reduction and the unaltered haloid, and in the next place because the short period of exposure does not produce a sufficient quantity of the product of reduction to render the latter visible. The invisible image thus consists of a layer of reduction-product of infinitesimal thinness, and the picture is afterwards made visible by the deposition of metallic silver on this reduction-product by the application of certain solutions known as 'developers,' the chemical

action of which will be described subsequently.

Daguerreotype. This process is historically interesting as having been the first method of photography with a silver salt successfully applied to the production of a picture from the image formed in a camera. It takes its name from Daguerre, who announced the discovery in 1839. The process is no longer used; it has been superseded by more rapid methods. order to prepare a Daguerreotype plate, a plate of copper is silvered, and the polished surface is exposed to the vapour of iodine and bromine alternately. The sensitive film is therefore a mixture of silver iodide and bromide. Silver iodide can act to some extent as its own sensitiser, but the substratum of metallic silver is chiefly effective in this capacity as it is capable of rapidly absorbing the halogen liberated by the action of light upon the sensitive surface. The invisible image is developed by exposure to the vapour of mercury, which condenses on the product of reduction but not on the unaltered haloid.

Collodion processes. In these processes the sensitive film consists of a silver haloid formed by double decomposition in collodion as a vehicle. Collodion is a solution of the tri- and tetranitrate of cellulose (collodion pyroxyline) in alco-hol and ether (v. vol. i. p. 716), and on coating a glass plate with this solution the solvents evaporate and leave a uniform layer of the pyroxyline attached to the plate. Some soluble iodide, NH₄I or CdI₂, sometimes mixed with a small quantity of a bromide, is first dissolved in the collodion, the plate is coated with this salted collodion, and when dry is sensitised by immersion in a silver nitrate solution. The sensitive surface in this process is therefore a silver haloid wetted with a film of silver nitrate solution, the latter playing the part of a sensitiser by absorbing the liberated halogen: 31, + 6AgNO, + 3H,O = 5AgI + AgIO, + 6HNO, By washing out the soluble salts after the plate has been removed from the silver solution the sensitiveness is practically destroyed, because the pyroxyline by itself has no halogen-absorbing power. On drying such a washed plate, and then coating it with a solution of tannin or some organic sensitiser, the sensitiveness is partially restored. Plates thus treated can be used in the dry state, and dry-plate photography by this method was made practically successful in 1861 by Colonel Russell.

Emulsion processes. All the photographic methods at present in vogue are comprised in this group. The silver haloid is precipitated in a finely divided state in some vehicle, usually gelatin, and the plates coated with this emul-sion are allowed to dry and are then ready for use. A brief description of a method for preis invisible, in the first place because of the very paring a gelatin emulsion will suffice to make

clear the general mode of procedure. The soluble bromide (potassium or ammonium), sometimes mixed with a little iodide, is dissolved in water, together with a certain quantity of the gelatin, and to this solution the calculated quantity of silver nitrate (previously dissolved in water) is added little by little with constant agitation. The quantities are so adjusted as to leave no excess of silver nitrate. The silver haloid is by this means precipitated in an extremely fine state of division in the viscid gelatin solution, with which it forms an emulsion. A stronger solution of gelatin is then mixed intimately with the first dilute emulsion, and the whole is heated on a water-bath for about an hour to become 'ripened.' cold, the semi-solid emulsion is washed by immersion in a fine state of division in cold water, so as to remove all soluble salts (nitrates formed by double decomposition, excess of soluble haloids, &c.). The washed emusion is then mixed with the necessary quantity of strong gelatin solution to reduce it to the required consistency, and the plates are coated and allowed to dry. Many variations in the details of mixing have been introduced, but these involve no change in principle. Ripening can also be effected at ordinary temperatures by the action of ammonia.

Ripening of emulsions. The process of ripening above referred to is necessary in order to increase the sensitiveness of the silver haloid. since the latter when first precipitated is comparatively insensitive. The increase of sensitiveness is no doubt due, partially if not wholly, to a physical change in the state of molecular aggregation of the silver haloid, as it is accompanied by a growth in the size of the particles and by a change in the absorption spectrum, the unripened emulsion transmitting more of the red rays, and, therefore, absorbing less of this part of the spectrum, than the ripened emulsion. The extreme sensitiveness of the emulsions at-present in use is thus due in great measure to the circumstance that the haloid is rendered sensitive to a much wider range of spectral colours than is the case with ordinary silver bromide precipitated in a non-emulsifying medium. The increased sensitiveness of a ripened emulsion may also be ascribed, in part, to the formation of an actual compound of the silver haloid with the gelatin or some constituent thereof (Meldola, Cantor Lectures on Photographic Chemistry, 1891. 20.

21).

Development of the photographic image. Acid development. In the wet collodion process the image is developed by the application of a solution of ferrous sulphate mixed with acetic acid and alcohol (to insure uniformity of flow). The film being already wet with silver nitrate solution, the action of the developer is simply to reduce this salt according to the reaction: 6AgNO₃ + 6FeSO₄ = 2Fe_c(SO₄)₂ + Fe_c(NO₃)₆ + 6Ag. Metallic silver is thus contained as a potential deposit in the mixed solutions, but its precipitation is retarded by the acetic acid, which plays the part of what is technically called a 'restrainer.' The finely-divided metal is deposited only on the product of photo-decomposition (the invisible picture), the density of the deposit being proportional to the amount of decompo-

sition on each portion of the sensitive surface. The image thus continues to gain in density as long as there is silver to feed it, so that the picture is built up by accretion and is raised in relief on the surface of the film. If the film is treated with dilute nitric acid after development, the picture is dissolved off, leaving the film in the same condition as before exposure, thus proving that the image is purely superficial. The ferrors sulphate developer, which acts in the manner described, is a type of the class of acid developers.

Alkaline levelopment. Gelatin emulsions contain no excess of silver nitrate, so that the foregoing process of development is inapplicable. The gelatin itself, being a bromine absorbent, is in this case the sensitiser. Development is effected in modern processes by means of an alkaline or neutral solution of some reducing agent, usually an easily oxidisable organic compound, such as ammonium pyrogallate, first introduced hy Colonel Russell in 1862. In this method the developer acts directly as a reducing agent upon the product of photo-reduction, replacing the latter by its equivalent of metallic silver. image at the same time gains in density by the further reduction of those portions of the unaltered silver haloid which are in immediate contact with the nascent silver being generated by the developer; the action is probably electrolytic, since the image goes on increasing in density as long as the developer can exert a reducing action. A very small amount of the silver deposit may also be due to the reduction of the minute quantity of silver actually dissolved out of the film by the ammonia or other solvent in the developer. In alkaline development the main portion of the silver image is therefore built up by growth from the silver haloid in the film, and after development the image can be dissolved out by dilute nitric acid, leaving its impression sunk in the gelatin, instead of leaving a plane surface, as in the case of a collodion picture similarly treated.1 The developers belonging to this class are all strong reducing agents capable of directly reducing the silver haloids, so that the action has to be moderated by means of restrainers, potassium bromide being generally employed for this purpose. The restraining action of this salt is probably due to its tendency to form a double potassio-silver bromide, which is more stable than the silver bromide itself. In addition to ammonium pyrogallate several other developers acting in a similar manner have come into use, Of these may be mentioned potassio-ferrous

to the equation: $3Br_z + 6FeC_zO_1 + 3K_1O_zO_4$ = $3Fe_z(C_zO_3)_z + 6KBr$. The bromine in this case is derived primarily from the reduction-product. Other developers coming under this category are an alkaline solution of hydroquinone (quinol), hydroxylamine, phenylhydrazine, and an alkaline salt of amido- β -naphthol-monosulphonic acid (Meldola, C. J. 39, 47), introduced by Andresen (Etkonogen). Among the most recently introduced developers are certain amido-phenols,

oxalate (Carey Lea, 1877), which acts according

¹ An able investigation of the connection between the density of the deposit of reduced silver and the period of exposure, &c., is published by Harter a. Driffield &C. f. v, 455; 10, 100; v. also other papers in same volume; also Armstrong, Conjerence No. of Journ. of the Camera Club, 1892, and discussion in same journal, July 1892).

amide-phenolic and carboxylic acids, and their alkyl derivatives, known as 'amidol,' 'metol,' &c. Those which contain the basic and hydroxyl substituents in the para-position seem to be the most effective (Hauff, Engl. Patents [1891] 15, 431; 20, 690).

In the processes of alkaline development the gelatin itself also acts the part of a restrainer by preventing too intimate a contact between the reducing solution and the silver haloid. Any viscous substance exerts this protecting influence (sugar, glycerin, &c.), and such compounds are sometimes called physical restrainers, to distinguish them from chemical restrainers, such as the acid in the ferrous sulphate developer or the potassium bromide in alkaline developers. A developer of very great reducing power is for this reason available in dry plate photography, and upon this fact largely depends the extreme sensitiveness of modern processes.

Development by vapour. The Daguerreotype picture was developed by exposure to mercury vapour, this metal having the property of condensing on the product of photo-reduction (the invisible image) but not on the unaltered silver haloid. It is not known whether the combination of the mercury with the reduction-product is of a chemical or physical nature. method of development is at present the sole

representative of its class.

Fixing the picture. The image developed by the foregoing methods is always on a back ground of unchanged silver haloid, which must obviously be removed before the picture can be exposed to white light. In the early days of photography strong solutions of potassium, solium, or ammonium chloride were used as fixing agents, these salts having the property of forming soluble double salts with the silver haloids. The action of these salts was, however, very imperfect, and a certain amount of undissolved silver haloid was always left in the film, which led on exposure to the gradual darkening and obliteration of the whole picture. Potassium cyanide has since been employed, this salt forming with the silver haloid an extremely soluble double cyanide: AgBr+2KCN =AgK(CN)2+KBr. The fixing agent now generally preferred is sodium thiosulphate (Sir J. Herschel, 1839); this salt, if used in excess, forming the extremely soluble sodio-silver thiosulphate Ag₂Na₄(S₂O₃)₃, 2aq: 2AgBr + 3Na₂S₂O₃ = Ag₂Na₄(S₂O₄)₂ + 2NaBr. If the fixing solution is dilute, the insoluble NaAgS₂O₃ is formed, which remains in the film and spoils the picture: AgBr + Na₂S₁O₃ = AgNaS₂O₃ + NaBr. After immersion in the fixing bath, the soluble salts are removed by thorough washing in a stream

Intensification, and reduction, of density. In cases where the image is wanting in density through under-exposure, bad light, insufficient development, &c., a process of intensification is resorted to. The process as applied to modern dry plates consists in substituting for the silver, of which the image is composed, some denser of which the image is composed, some denosit. Thus, by immersing a negative in as solution of mercuric chloride, the image is bleached by conversion into a mixture of mercurous and silver chlorides: 2Ag+2HgCl₂=2AgCl+Hg,Cl₂. By treating this mixture

with a solution of potassic-ferrous exalate the image is restored in silver and mer-cury, and thus in a condition of increased density: $2AgCl + Hg_{\circ}Cl_{2} + 4I^{\circ}eC_{\circ}O_{4} + 2K_{\circ}C_{\bullet}O_{4}$ = $2Ag + 2Hg + 2Fe_{\circ}(C_{\circ}O_{4})_{3} + 4KCl$. Many other density: intensifiers are known, some acting by simple substitution, such as auric or platinic chloride: 4Ag + PtCl, $6Ag + 2AuCl_{s} = 2Au + 6AgCl_{s}$ or = Pt + 4AgCl; others giving rise to a mixture of products together denser than the original deprosit, e.g. lead or uranium ferricyanide: $4Ag + 2Pb_xFe_y(CN)_{xy}^{-2}Ag_xFe_y(CN)_{xy}^{-2}Ag_xFe_y(CN)_{xy}$. In cases where too dense an image has been obtained, and it is desired to thin it down, a reducing solution is applied; the chemical principle may be described as a conversion of the metallic silver into some compound which can be simultaneously removed by a solvent such as sodium thiosulphate. Thus a mixture of potassium ferricyanide with thiosulphate is often used for gelatino-bromide plates: $4Ag + 2K_cFe_c(CN)_{12} = Ag_iFe_i(CN)_a + 3K_cFe_i(CN)_a$. The silver ferro-cyanide is dissolved off by the thiosulphate, as fast as formed: Ag, Fe(CN), + 6Na, S,O, = $2\Lambda g_2 Na_1(S_2O_3)_3 + Na_1 Fe(CN)_6$. When the necessary reduction of density has been attained, the action of the solution is stopped by washing the film with water.

Reversal of the photographic image and allied phenomena. Any influence which affects a sensitive film in a way similar to the action of light gives rise to a developable image. Thus mechanical pressure-marks produced by rubbing a film with a glass rod can be developed by ferrous oxalate &c., so as to show a corresponding set of dark streaks. It is probable that the friction in this case induces a minute amount of chemical change between the sensitive haloid and its associated sensitiser (gelatin, &c.), this small quantity of reduction-product being afterwards exaggerated by the cumulative action of the developer. Whether the compound resulting from this mechanical action is identical with that produced by the action of light is at pre-ent uncertain, but the associated sensitiser appears to be as essential to the success of the phenomenon in this case as in the ordinary formation of the invisible picture by the action of light. The sensitiser, as has already been explained, is an essential part of any photographic system, and this is best shown by the so-called 'reversal' of the photographic image by over exposure or other means. It has been found that a very strong light allowed to act on a sensitive film for too long a period gives a weaker image on development than is produced with a shorter exposure, and that under some circumstances the image is even 'reversed,' i.c. the high lights come out lighter, on development, than the shadows. The explanation of this phenomenon is probably to be found in the circumstance that while the silver haloid is losing halogen under the influence of light, the sensitiser is simultaneously becoming halogenised, so that when the charge of halogen in the latter exceeds a certain amount the chemical chaffge sets in in a reversed direction, i.e. the halogenised sensitiser begins to re-halogenise the product of photo-decomposition and thus to destroy the invisible image. That this explanation is, in the main, correct in principle, is shown by the fact that the most sensitive processes are just those which

are most prone to give rise to reversal, because it is in such films that the sensitiser becomes most rapidly halogenised. A preliminary exposure to diffused light also promotes reversal, because this imparts a certain initial charge of halogen to the sensitiser. Then, again, oxidising agents favour reversal, because these lessen the halogen-absorbing power of the sensitiser: on the other hand, reducing agents prevent reversal, because they retard or prevent the halogenation of the sensitiser. Thus plates exposed in ozone or in solutions of K₂Cr₂O, and K₂Mn₂O₈ are easily reversed, while nitrites, sulphites, &c., prevent reversal (Abney). Atmospheric oxygen in many cases probably plays a part in the process by assisting in the liberation of halogen from the sensitiser. Thus, by way of illustration, if a plate be given a preliminary exposure to diffused light, and be then coated with a solution of potassium iodide, a completely reversed image can be obtained on exposure in the camera and development. The chemical reaction is in this case: $4KI + 2H_2O + O_2 = 2I_2 + 4KOH$. The iodine is here absorbed by the reduction-product, and thus reverses the picture; the surface of the film is in fact the sensitiser in this case, and the potassium iodide is the photo-sensitive compound.

Waterhouse has recently found that a small quantity of a thio-carbamide added to the developer produces a 'reversed' image (Photo. News, 1890. 727, 743, 804; v. also Journ. of Camera Club, July 1892; also Rawlins, S. C. I. 10, 18).

Printing processes. It is obvious that the photographic image, after normal development, represents the object with its lights and shadows reversed, i.e. the picture is a negative one. A positive print is obtained by exposing suitable sensitive surfaces under such a negative.

Silver prints. A very general method of obtaining silver prints depends upon the use of a sensitive surface (usually paper) consisting of a mixture of silver chloride and an organic compound of silver with albumen, this surface being obtained by first coating the substratum with a solution of albumen containing ammonium chloride, and then (when dry) floating on a solu-tion of silver nitrate. The printing is carried on to the required depth of colour, and the visible print consists of the reduction-products of silver chloride, and of the organic silver compound. which is also susceptible of photo-reduction. To correct the reddish colour of these mixed reduction-products the print is 'toned' by immersion in a solution of auric chloride, kept neutral by the addition of sodium carbonate, acetate, or phosphate, chalk, borax, &c. The function of these salts is to neutralise the hydrogen chloride liberated by the reduction of the auric chloride by the reducing compounds which constitute the picture. The gold is thus precipitated in a state of fine division only on the products of photodecomposition (the picture), and imparts the desired tone. The accumulation of acid in the toning bath retards the precipitation of gold, and

¹ Potassium bromido similarly acts as a reversing agont though to a less extent. It is for this reason that every trace of this sath has to be washed out of a gelatino-bromido emulsion after the process of ripening, since the presence of the soluble bromide materially diminishes the sensitireness of the smulsion. the deposit is not of a good tone; hence the necessity for the presence of one of the salts referred to. The unaltered silver chloride &c. is removed by fixing with thiosulphate, and washing. In some recent processes the albumenised silver paper is replaced by paper coated with gelatino-bromide or chloride emulsion, a short exposure being given, and the invisible (positive) picture being developed in the usual manner.

Printing with iron and uranium salts. Ferric and uranic salts in the presence of organic sensitisers become reduced on exposure to light, and the ferrous or uranous compounds thus formed can be developed by treatment with potassium ferricyanide or other salts which give coloured products with the ferrous or uranous, but not with the unreduced, salts. Thus paper coated with ferric oxalate gives a faint image of the ferrous salt, which comes out as a deepblue print on development with ferricyanide: 6FeC₂O₄+2K₄Fo₂Cy₁₂=2Fo₃(Fe₂Oy₁₂)+6K₂Cy₀Many printing processes depending upon the foregoing principles have come into use, and will be found described in works on practical photography.

Platinotype. Prints in finely-divided platinum can be obtained by exposing a surface coated with a mixture of ferric oxalate and potassium chloroplatinite under a negative. The ferrous salt thus produced does not react with the chloroplatinite till the picture is developed by immersion in a solution of potassium oxalate, which dissolves the ferrous oxalate, with the formation of a double salt, which simultaneously reduces the chloroplatinite:

3K.PtCl. + 6FeC.O.

3K,PtCl₁+6FeC₂O₄
= 3Pt+2Fe₂(C₂O₃+Fe₂Cl₄+6KCl. The soluble salts are then removed by washing with dilute hydrochloric acid, and finally with water.

Pigment printing. A mixture of gelatin with potassium dichroniate undergoes a chemical change on exposure to light, in the course of which the dichromate is reduced and the gelatin at the same time becomes insoluble in water. The chemical composition of this insoluble gelatin is unknown, but it appears to contain an oxide of chromium as an essential constituent (Eder). Many printing processes are based upon this property of gelatin, such, for example, as the so-called carbon and pigment prints, in which the finely divided carbon or pigment is intimately mixed with the gelatin solution and the mixture sensitised by the addition of dichromate. After exposure under a negative the picture is developed by warm water, which dissolves away those portions of the tissue unacted upon by light. Many of the photo-mechanical printing processes de-

pend also on this property of gelatin.

Photo-etching processes. When a layer of asphalt or bitumen is spread over a surface and exposed under a design, those portions of the film which are acted on by light become insoluble in hydrocarbon oils, so that the design can be developed by such solvents, and the surface, if of metal, can be converted into a printing block by etching with acid. The change experienced by the bitumen is probably the result of photo-chemical oxidation. The processes based on this property are much in vogue at the present time under various modifications. This action of

light upon bitumen furnished the earliest successful permanent reproduction of the camera sisture (Joseph Nicephore Niepoe, 1824).

Bibliography.-It has not been considered advisable in the present article to give the authority for every statement, as most of the results achieved by photographers are to be found in publications rarely consulted by chemists. The following general works contain practically all that is known of photographic chemistry at the present time : - Robert Hunt, Researches on Light, 2nd edit., 1854; E. Becquerel, La Lumière, Paris, 1867; J. W. Draper, Scient fic Memoirs, a collection of reprints, 1878; J. M. Eder, Ueber die Reactionen der Chromsäure u. der Chromate auf Gelatine, Gummi, Zucker, &c. Wien, 1878; J. M. Eder, Ausführliches Handbuch der Photographie, Halle, 1884 9; H. W. Vogel, La Photographie des Objets Colores avec leurs Valeurs Reelles, Paris, 1887; Pizzighelli and Hübl, La Platinotypie, Paris, 1887; W. de W. Abney, Treatise on Photography, 5th edit., 1888; by the same author, Instructions in Photography, and Photography with Emulsions; Chapman Jones, Introduction to the Science and Practice of Photography, 1888; R. Meldola, The Chemistry of Photography, 1889; H. W. Vogel, Handbuch
der Photographie, Berlin, 1890. 1.

PHOTOSANTONIN v. SANTONIN.

PHRENOSIN C4H,NO. A substance oc-

curring, according to Thudichum (J. pr. [2] 25,

19), in the brain.

PHTHALACENE C₂₁H₁₆. [173°]. Formed by reduction of phthalacone carboxylic ether with HI and P at 170° (Gabriel, B. 17, 1390). Crystals (from HOAc). Yields O₂₁H₁₈Br [184°], which is oxidised by K,Cr₂O, and HOAc to C₂₁H₁₈BrO [c. 200°]. Fuming HNO₂ and HOAc vield di-nitro-phthalacenc, which separates from hot nitro-benzene in yellow needles. K₂Cr₂O, and HOAc oxidise phthalacene to 'phthalacene oxide' C₂H₁O [211°-214°], which yields an oxim C₂H₁(NOH) [205°]. PHTHALACENIC ACID C₂H₁, CO₂H. [247°].

Formed by heating phthalacene-oxide with soda-lime (Gabriel, B. 17, 1399). Crysta's.—A'Ag. PHTHALACONE CARBOXYLIC ACID

C₁₁H₁₁O₂(CO₂H). [281°]. Formed by dissolving its ether in conc. H₂SO₂ and pouring into water (Gabriel, B. 17, 1389). Minute yellow needles, sol. hot alcohol. The acid yields a dioxim $C_{s_1}H_{11}(NOH)_2CO_2H$ [273°] and the salts KA'aq and NaA'aq. Zinc-dust and NaOHAq yield a tetrahydride C₂₂H_{1c}O₄, melting above 280°, which

gives AgA', crystallising in needles.

Ethyl ether EtA'. [211°]. A product of the action of phthalic anhydride and NaOAc on acetoacetic ether at 140°. Yellow needles, sol. hot HCAc. Yields a di-nitro- derivative [above 280°] and a dioxim C₂₁H₁₁(NOH) CO₂Et [264°]. 2807 and a dioxim Caldinition 1.00 p. 100 p.

CHO.C.H.CO.H.[1:2]. [97°]. Formed, together with C.H.Co. (221°), by heating a bromophthalide with water (Racine, B, 19, 778; A. 239, 78; C. R. 106, 947). Formed also by boiling a brown of the control o ing penta-w-chloro-o-xylene with water (Colson a. Gautier, Bl. [2] 45, 509). V. sol. water, alcohol, and ether. Reduces ammoniscal AgNO₄.

Phenyl-hydrazine yields C₁,H₁₈N,O [103°]. Alcoholic NH₅ forms C_{...}H₁₈N,O₆ [187°], while an alcoholic solution of aniline gives C_{1,H1}NO₂ [174°]. Ac,O at 200° forms CHO.C.H.,CO.Ac [60°-63°]. Ures forms NH₂,CO.N:CH.C.H.,CO.H. [240°].—CaA', 2sq.—AgA': slendor needles.

Ethers MeA'. [44°].—EtA'. [66°].

Anhydrids C₁₆H₁₀O₃. [221°]. Got by heating the acid with bromo-phthalide.

Oxim CH(NOH).C.H.,CO.H. [120°].

Oxim CH(NOH).C,H,.CO,H. Formed by adding hydroxylamine hydrochloride to a cold aqueous solution of the acid. In an alcoholic solution the product is C.H. CO.O [120°], which is converted by heat first into CN.C.H. CO.H and then into phthalimide (Allendorff, B. 24, 2346, 3264).

Isomeride v. p-Aldehydo-Benzoic acid.
Diphthalaldehydic acid v. Di-Phthalyl-Lag-TONIC ACID

PHTHABAMIC ACID v. PHTHALIC ACID. PUTHALAMIDE v. PHTHALIG ACID.

ISOPHTHALAMIDINE C.H., N. i.e.
C.H., (C(NH).NH.), [1:3]. Formed from
C.H., (C(NH).OEt), and alcoholic NH, (Luckenbach, B. 17, 1432). Small needles, insol. benzene and ether, v. sol. alcohol and water. Its aqueous solution soon decomposes, giving off NH, - B"H,Cl2: needles, v. sol. water.—B"H,PtCl4.—

B''H_SO, -B''2HNO, -B''HNO,: needles (Grabowski, A. 205, 168).—CH_(NAg,NH_),

ISOPHTHALAMIDOXIM C,H₁₀N₁O, i.e.
C,H₁(C(NOH),NH_), [193°]. Formed from C.H.Cy. [1:3] and hydroxylamine (Goldberg, B. 22, 2976). Prisms (from alcohol) containing aq?, v. sol. hot water.

Phthalanil v. Phenylimide of PHTHALIC ACID. PHTHALBENZO-TÖLUIDE v. Phthalyl-

AMIDO-TOLYL PHENYL KETONE. PHTHAL-o-CYANO-BENZYL-IMIDE

O-CYANO-BENZYL-PHTHALIMIDE. PHTHALEÏNS. Colouring-matters obtained by condensation of phthalic anhydride with phenois (e.g. Phenoi. Phithalein and Fluon-escein). They may be reduced to colourless 'phthalins,' which are re-oxidised by air to phthaleins.

PHTHALIC ACID C,H,O, i.e. [1:2] C.H. (CO.H)... Mol. w. 166. [184°] (Lossen, A. 144, 76); [203°] (Ador, A. 164, 230; Baeyer, A. 269, 184). S. 54 at 14°; 18 at 99° (Graebe, H. 230, 331; S. (alcohol) 10 at 15° (Bourgoin, Bl. [2] 29, 247); S. (ether) 684 at 15°. H.C. 771,600. H.F. 187,400 (Stohmann, J. pr. [2] 48, 540); 153,000 (von Rechenberg). S.H. (175° to 119°) 256 (Hess, A. Ch. [2] 35, 410). S.H. (from

Formation .- 1. By the action of nitric scid on naphthalene, naphthalene dichloride, alizarin, purpurin, munjistin, naphthoquinone, o-toluic acid (Laurent, A. Ch. [2] 61, 113; Marignac, A. 42, 215; Schunck, A. 66, 197; Wolff a. Strecker, A. 75, 12, 25; Stenhouse, A. 130, 334; Liebermann a. Dittler, B. 6, 94°; Piccard, B. 12, 579; Beilstein a. Kurbatoff, A. 202, 215).—2. By the action of various oxidising agents on naphthalene (Lossen, A. 144, 71; Hermann, Z. [2] 4, 551; Depouilly, C. R. 56, 82; Häussermann, D. P. J. 223, 310).—3. A product of the action of MnO, and H₄SO, on benzene (Carius, Z. [2] 4, 705; A. 148, 60).—4. By oxidising o-toluic acid with KMnO₄ (Weith, B. 7, 1057).—5. By

oxidising isoquinoline with alkaline KMnO₄ [Hoogewerff a. Van Dorp, R. T. C. 4, 285].—6. By heating salicylic acid with H₂SO₂ and K₄FeO₇ (Guyard, Bl. [2] 29, 247).—7. By heating resorcin or salicylic acid with formic acid and H₂SO₄ (G.).—8. By the action of a hot solution of accompany paragraphs are suppression as a superposition of a solution tion of cuprous potassium cyanide upon o-diazo benzoic chloride (from anthranilic acid), and subsequent saponification of the product (Sandmeyer, B. 18, 1499).

Properties .- Trimetric plates. Yields an anhydride when heated. Insolachlorotorm.

Reactions .- 1. Distillation with lime yields benzoic acid and benzene. - 2. Sodium-amalgam reduces it to a dihydride .- 3. Chromic acid mixture oxidises it to CO₂ (Fittig, A. 156, 242).— 4. The soid aniline salt A"H(NH₂Ph) of orthophthalic acid loses H2O when its aqueous solution is boiled, phenyl-phthalimide crystallising out. The para- and meta- phthalic acids do not react in this way; the reaction therefore serves as a means of separating ordinary phthalia acid from its isomers (Michael a. Palmer, B. 19, 1376; Am. 9, 202).

Salts.-(NH.)HA": prisms, v. sol. water. BaA": v. 8l. sol. water (Carius, A. 148, 04).—
 Ba₄A"₂O: monoclinic prisms.—CuA"aq.—PbA".
 —Ag₂A": crystalline pp.—A niline salt: needles [146°] (Clarke, B. 12, 1066).
 Di-methyl ether Mc₂A" (280° i.V.) at 734 mm. (Graebe, B. 16, 860). H.F. 164,600 (Stohman) (Graebe, B. 16, 860).

mann, J. pr. [2] 40, 353).

Mono-ethyl ether EtHA". Formed by heating phthalic anhydride with absolute alcohol at 100° (Michael, Am. 1, 413). Liquid, m. sol. water. Decomposed by heat into phthalic

anhydride and alcohol.—Ba(EtA"),.—AgEtA". Di-ethyl ether Et,A". (295° cor.). Got by passing HCl into an alcoholic solution of phthalic acid (Graebe a. Born, J. 1866, 411). Formed also from phthalyl chloride and alcohol. Liquid. Not attacked by hydroxylamine (Jeau-renaud, B. 22, 1273). When warmed with When warmed with NaOEt and EtOAc it yields the compound C_eH₄<CO>CH.CO₂Et [75°..78°] (Wislicenus, A. 246, 349). PCl, followed by sodium malonic ether forms the acid C21H16O10 [c. 180°] (Zelinsky, B. 20, 1010).

Phenyl ether Ph.A". [70°]. Formed by heating phthalyl chloride with phenol (Schreder, B. 7, 704; von Gerichten, B. 13, 419). Colourless crystals.

Anhydride C.H.O. i.e. C.H. COOO. Mol. w. 148. V.D. 5·26 (calc. 5·13) (Troost, C. R. 89, 851). [128]. (284·5' i.V.). H.C.p. 784,000. H.F. 106,000 (Stohmann, J. pr. [2] 40, 139). Formed by heating phthalic acid alone or with AcCl (Laurent; Anschütz, B. 10, 326). Formed also by the action of lead nitrate on phthalyl v. sol. alcohol and ether, sl. sol. cold water.

Reactions.—1. When heated with phenols it yields phthaleins, with elimination of water (Baeyer, B. 7, 968).—2. Heated with NaOAc and HOAc it yields phthalyl-acetic acid C10HaOa, while phenyl-acetic acid gives benzylidene-

phthalide. Phenyl-acetonitrile gives rise to C.H. COO, [165°], and isobutyric acid and ZnOl, at 250° give a ketone C₁₁H₁₀O₂ [96°]. 3. Boiling with NaOAo and phenoxyacetic acid yields C₂H₄:C₂O₂:CH.OPh [143°] while p-totyloxy-acetic acid and sodium acetate give rise to C,H,:C,O2:CH.OC,H,Me [174°] (Gabriel, B. 14, 922) .- 4. Acetoacetic ether gives C, H, Bz, and phthalacone carboxylic ether .- 5. On heating with succinic acid and sodium succinate it yields CO₂ and C₁₈H₁₀O₄ [above 300°].—6. Di methyl-quinolme and zine chloride at 200° give C.H.;C.O.;C.,H.,N [238°] (Beyer, J. pr. [2] 33, 407).—7. Ethenyl-amido-phenyl-mercaptan and ZnCl₂ at 200° give C₈H₄C_S C.CHC_{CO}C₈H₄ crystallising in yellow needles [above 320°] (Jacobson, B. 21, 2630).—8. Cyanethine forms, on heating, C_bH₁₃N_{...}N:C₂O₂:C_cH₁ [128°] (E. von Meyer, J. pr. [2] 30, 262).—9. Coal-tar picoline and zinc chloride at 200° form pyrophthalone C_bH₁O₂:Cli.C,H₁N [above 260°] (Jacobsen a. Reimer, B. 16, 2604) crystallising from alcohol in yellow plates.—10. Benzente and AlOl, yield a hearzoth-honyoic soid and other aromatic by o-benzoyl-benzoic acid, and other aromatic hydrocarbons act in like manner (Friedel a. Crafts, C. R. 92, 833) .- 11. Benzyl chloride and zincdust at 75° yield C_{so}H_{sc} (?) [73°] (Wislicenus, A. 248, 68).—12. On heating with amines and amides, phthalic anhydride yields derivatives of the imide and amide of phthalic acid; thus acetamide yields phthalimide and HOAc, while ethylamine yields ethyl-phthalimide. Secondary amines form derivatives of the amic acid and of the amide (Piutti, A. 227, 181; G. 16, 1, 251) .-13. Amido-acids are converted by phthalic an-hydride into their phthalyl derivatives (Reese, A. 242, 1).-14. On fusion with sinc-dust phthalio anhydride gives diphthalyl. Zinc-dust and HOAc yield a mixture of phthalide, diphthalyl

dihydride C_eH, CO.00.CO C_eH₄, [229°] and CH, [199°], which is reсо,н.с.н,.сп..сп/

CO₂H₂CH₂CH₂CC₂H₃CC₂H₁CC₂H₂(Wislicenus, B. 17, 2178).—15. Tri-anido-phenol (picranic acid) forms (C₂H₂C;N₂C;H₂C) Habove 300°] converted by potash into the compound (CO₂H₂C;H₂CONH)₂C;H₂OH [above 300°], from which nitric acid produces the quinone (C,H,O,:N),C,H,O, [277°] reduced by SO, to (C,H,O,:N),C,H,(OH), [above \$10°] (Piutti, G. 16, 254).

10, 209).

Chloride C₆H₁ CCl₂ O. Phthalyl chloride. [0°] (Wisehin, A. 143, 259). (275°) at 726 mm. S.G. ²⁰ 1.4089. $\mu_{\rm s} = 1.569$ (Brithl, A. 235, 14). Formed by heating phthalic acid with PCl, for 2 hours at 190 (H. Müller, Z. 1863, 257; Graebe, A. 238, 320). Oil, absorbs moisture from the air, forming phthalic anhydride. Slowly onverted into phthalic acid by water or Na₂CO₂Aq. Reduced by zinc and HClAq to phthalide. Sodium-amalgam and HOAc form C₂H₄(CH₂OH)₂. PCl₃ forms two isomeric chlorides C₃H₄ CCl₂ O and C₄H₄ CCl₃, one melting the control of ing at 88° and boiling at 275°, the other melting

at 47° and boiling at 262°; both are converted by aniline into C_eH₄ C(NPh) NPh [153°] (von Gerichten, B. 13, 417; Claus, B. 19, 1188). Excess of PCl, yields chloro-benzoic acid, CCl,, and other products (Claus). Aqueous NH, forms C₈H₁O₂(NH₂)₂ [90°] not identical with phthalamide, but converted by HClAq into C,H,O,(NH) [145°] which is changed by fusion into the isomeric phthalimide [228°] (Auger, A. Ch. [6] 22, 303; cf. Kuhara, Am. 3, 26). Dry NH, acting on the benzene solution behaves in like manner. Hydroxylamine yields C₂H₄:C₂O₂:NOII [230°] (v. vol. ii. p. 738). o-Amido-phenyl mercaptan hydrochloride forms $C_{20}H_{12}N_{23}$ [112°] (Hofmann, B. 13, 1233). $Z_{11}M_{12}$ (Forms $C_{10}H_{12}N_{23}$ [112°] (Bosantzeff, Bl. [3] 1, 166). Zniči, followed by water gives, in like manner, C12H14O2 [54°] (250°).

Semi-nitrile v. o-CYANO-BENZOIC ACID.

Amic acid C, II (CO.NH.) CO, II. Phthalamic acid. [c. 140°] (Auger); [149°] (Aschan, B. 19, 1401). Formed by heating phthalic anhydride with alcoholic NH, or phthalimide with baryta-water. Prepared by evaporating phthalic anhydride with NH, Aq, and decomposing the resulting ammonium salt by HCl (Auger, Bl. [2] 49. 349). Prisms, sl. sol. water, v. sol. alcohol. Converted by heat into phthalimide, and by hot water into hydrogen ammonium phthalate. cess of HClAq forms phthalic acid.—NH,A'.—KA'.—BaA'.,—BaA'., aq.—AgA': needles, v. sl. sol. water (Landsberg, A. 215, 197).

Isoamyl-amic acid 180amyt-amic acia C₄H₁(CO₂H),CO.NHC₂H₁₁. Isoamyl-phthalamic acid. [115°]. Formed by warming isoamyl-phthalimide with KOHAq (Neumann, B. 23, 998). Crystalline pp.—AgA'.

Phonyl-amic acid C.H.(CO.H).CO.NHPh. Phenyl-phthalamic acid. Phthalanilic acid. [192°]. Got by boiling phenyl-phthalimide with NH,Aq and some alcohol (Laurent a. Gerhardt, A. Ch. [3] 24, 188). Plates, sl. sol. cold water, v. sol. alcohol.

Phenyl-ethyl-amic acid C₁₆H₁₅NO₃ i.e. C₄H₄(CO₂H).CONPhEt. Phenyl-ethyl-phthal. Phenyl-cthyl-phthal. amic acid. Got by dissolving phthalic anhydride in ethyl-aniline (Piutti, G. 13, 545; A. 227, 185). Heavy oil, v. sl. sol. water.

Di-phenyl-amic acid C₂H₄(CO₂H).CONPh₂. Di-phenyl-phthalamic acid. [148°]. Made from diphenylamine and phthalic anhydride (P.). Hard prisms, sl. sol. ether, v. sol. alcohol. AgA'.

o-Tolyl-amic acid
C.H.(CO.H).CONHC.H.Me. Got by boiling
o-toly-phthalimide with NH.Aq (Kuhara, An.

9,51). Needles.—Ag₂C₁,H₁₁NO₃: pp.
m. Methyl-benzyl-amic acid
C₆H₄(CO₂H).CO.NHCH₂C₆H₄Me. [13 [131°]. from m-xylyl-phthalimide and caustic soda (Brömme, B. 21, 2700). Needles, sol. alcohol.— AgA': white pp.

ψ-Cumyl-amic acid C₂H₄(CO₂H).CO.NHC₂H₄Me₂. Phthal-ψ-cumidic acid. [179°]. Needles, v. sol. alcohol, sl. sol. ether (Fröhlich, B. 17, 1808).

Naphthyl-amic acids
C.H.(CO.H).CO.NHC.H., The (a)-acid [185°]
is got from (a)-paphthyl-phthalimide. The (β)-

acid crystallises from alcohol in tables (Piutti. G. 15, 480).

Phenyl-oxy-ethyl-amic acid C₄H₄(CO,H).CO.NH.C₂H₄.OPh. [125°] Formed by warming phenyl-oxyethyl-phthalimide with KOHAq (Schmidt, B. 22, 3255).

p-Tolyl-oxy-ethyl-amio acid C.H. (CO.H).CO.NH.CH,.CH,.O.C,H,Me. [137°]. Formed from the corresponding imide which is

got by heating potassium phthalimide with C₆H,Mc,QC,H,Br (Schreiber, B. 24, 191).

Phenyl-andido-phenyl-amic acid
C₅H₁(CO.II).CO.NH.C₆H,NIIPh. [120°-130°].

Powder (Gabriel, B. 22, 2223).

Benzoylethyl-amic acid C.H.(CO.H).CO.NH.CH. CH.Bz. Propiophenone. phthalamic acid. [140°]. Made from the imide (Schmidt, B. 22, 3251). Needles.—AgA': pp. Di-sulphido-di-ethyl-amic acid

(C.H.(CO.H).CO.NH.CH.,CH.),S., [130°]. Formed from stllphocyano-ethyl-phthalimide

rotined from supprocyano-ethyl-pathalimide and (10 p.c.) KOHAq (Coblega, B. 24, 2131). Scales. HClAq at 180° forms S₂(C₂H₁NH₂)... Uramic acid C₃H₁(CO₂H).CONH.CO.NH... Phthaluric acid. S. 3°5 at 99°. Formed by leating phthalic anhydride with urea at 115° control of the control (Piutti, A. 214, 19; G. 12, 173). Silvery scales, sol. alcohol. May be converted by POCl, into C₆H₄ CO.NH CO, which yields AgC₆H₅N₂O₆.

Salts.-NaA' 2aq.-BaA'2.-AgA': needles. Thio-uramic acid

C₆H₄(CO₂H).CO.NII.CSNH₂. [172°]. Got by heating phthalic anhydride with thio-ures (P.).

Silvery needles (from alcohol).—BaA'₄7a₄7a₄.

s-Amide C₁H₁(CO.NH₂)₂. Phihalamide.
[220°] (Bülow, A. 236, 188 Formed from phthalimide and cold NH₃Aq (Aschan, B. 19, 1399). Minute crystals, insol. cold water, alcohol, and ether. Boiling water converts it into phthalimide. Alkaline KOBr at 80° forms C₂H₄CO.NH (Hoogewerf a. Van Dorp, R. T. C.

10, 9).

 $C_4H_4 < CO \longrightarrow 0$. u-Amide[c. 90]. Formed from phthalyl chloride and NH,Aq (Auger, A. Ch. [6] 22, 304). Long transparent prisms, v. sol. water, sol. hot alcohol. AgNO. ppts. C,H,O,NAg in white lustrous scales. NH. being eliminated.

Phenyl-ethyl-amide C₂H₄CO(NPhEt)₂>0. [141°]. Formed by heating the ethyl-aniline salt of phenyl-ethyl-phthalamic acid above 200° (Piutti, G. 13, 547; A. 227, 187). Prisms, insol. water, sol. alcohol and ether. Not attacked by KOHAq, but split up by potash-fusion into phthalic acid and ethyl-aniline.

Di-phenyl-amide C.H.; C.O., (NPh.), Di-phenylamine-phthalein. [238]. Formed from phthalyl chloride and diphenylamine (Lellmann, B. 15, 830). Formed also by boiling, phthalic anhydride with diphenylamine (P.). Needles (from alcohol). H₂SO, containing HNO, forms an intense violet solution.

m-Phenylene-diamids C.H.O.:N.H.;C.H., [179]. Formed, together with (C.H.O.:N.J.C.H., [252°]), by fusing m-phenylene-diamine with phthalic anhydride (Bieder mann, B. 10, 1160). Nodules.

p-Phenylens-diamids $C_0H_1:C_2O_2:N_2H_2:C_0H_4$. [182°]. Converted by warming with dilute HClAq into a base $C_3:H_2:N_0O_4$ and $(C_0H_1:C_2O_2:N)_2C_0H_4$ [295°] (Biedermann, B. 10, 1163).

u-Imide $C_{\bullet}H_{\bullet} < C(NH) > 0$. u-Phthal-

imide. [c. 145°]. Formed by the action of HClAq on the *u*-amide (Auger). Slender needles, exactly resembling the s-imide, into which it changes when heated. Differs from the s-imide by decomposing moist BaCO, in the cold, hence it may possibly be o-cyano-benzoic

s.Imids C.H. CONH. Phthalimide.

[228°]. Formed by heating C_sH₄(CO₂H)(CO₂NH₄) or C₄H₄(CO₂H).CONH₂ (Laurent, A. 41, 110; A. Ch. [2] 61, 121; [3] 23, 119; Lansberg, A. 215, 181). Got also by heating the u-gnide, and by the action of CuCy₂ and KCy on o-diazo-benzoic acid (Sandmeyer, B. 18, 1499). Sixsided prisms (from ether). May be sublimed. Reduced by tin and HCl to phthalidine C, H, O(NH) (Graebe, B. 17, 2598). When distilled with steam (Graebe, B. 17, 2098). When distrible with steam over heated zine-dust it yields $C_{15}H_{11}N$ [100°] (Gabriel, B. 13, 1684). Boiling Ac₂O forms $C_{8}H_{1}$: $C_{2}O_{2}$:NAc [132°-135°] (Aschan, B. 19, 1398). Amyl alcohol and Na reduce phthalimide to o-methyl-benzyl-amine (Bamberger, B. 21, 1888). Yields benzonitrile when distilled with lime (Reese, A. 242, 5). Alkaline KOBr at 80° forms o-amido-benzoic acid (Hoogewerff a. Van Dorp, R. T. C. 10, 8) C, II, O, NK. Formed from phthalimide and alcoholic potash (Cohn, A. 205, 301; Gabriel, B. 20, 2225). Plates, converted into potassium phthalamate by boiling water. Converted by alkyl iodides into alkylwater. Converted by alkyl iodides into alkylphthalimides. [1:2]C,H₄(CH,Br)₂ gives rise to C₂H₄(CH,N:C₃H,O₂)₂[253], while the m-isomeride melts at 237°. Reacts with epichlorhydrin, forming C,H,O,N.C,H,O [201*] (Goedeckemeyer, B. 21, 2689) with (a) - diehlorhydrin, forming (O,H,O,N.CH₂),CHO.OII (201*), and with \(\gamma\)-bromobutyronitrile, forming C,H,O,N.CH.,CH.,CH.,CN. [81*5*] (Gabriel, B. 22, 224, 3337; 23, 1771).

C,H,O,NAa. — (C,H,O,N),Mg; white pp.— (C,H,O,N),Cu aq. — (C,H,O,N),Cu daq. — (C,H,O,N),C

Imidoxim $C_sH_sN_2O_2$ i.e. $C_oH_4 < {CO \choose CO} > O$.

[250°]. Formed by heating o-cyano-benzoic ether with an alcoholic solution of hydroxylamine at 90° for a long time (Müller, B. 19, 1498). Needles (from dilute alcohol), insol. bonzene. Boiling with HClAq and FeCl, converts it into phthalimide.

Methyl · imide C,H,O,:NMe. [132°]. (286°). Formed from potassium-phthalimide and MeI at 150° (Gracho, B. 17, 1174; A. 247, 302). Needles, reduced by tin and HCl to C.H.,NO [120°] (300°), which yields a gold salt [196°].

Ethyl imide C.H.:C.O.NEt. Ethyl-phthalimide. [79°]. (282°) at 720 mm. Formed by distilling a solution of phthalic anhydride in aqueous ethylamine; and formed also from potassium phthalimide and EtI (Michael, B. 10, 1645; Graebe, A. 247, 302; Wallach a. Kamenski, B. 14, 171). Needles. Br at 140° forms C₁₀H₆Br₃NO₂ [c. 189°]. Bromo - ethyl - imide

C,H,O,:N.CH,,CH,Br. [83°]. Formed from C_aH₁O_c:N.CH_.CH_aBr. [83°]. Formed from potassium phthalimide and C_aH_aBr_c (Gabriel, B. 20, 2225; 21, 566; 22, 1137). Needles. Converted by aniline into phenyl-amido-ethyl-phthalimide [10°], and by p-toluidine into both (C_aH₁O_c:N.C_aH₁),NC_aH_aMe [200°] and C_aH₁O_c:N.C_aH_a,NHC_aH_aMe [96°]. \(\psi - \text{Cumidine} \) form (C_aH₁O_c:N.C_aH_a,NHC_aH_aMe, [146°], while (a)- and (β)-naphthylamines form compounds C,H₁O₂:N.C.H₁.WHC₁₀H₁ [158°] and [141°] respectively (Newman, B. 24, 2196). Potassium sulphocyanide forms C,H,O,:N.C,H,SCy [108°] (Coblenz, B. 24, 2131).

Sulphydro-ethyl-imide C_aH₁O₂:N.C.H.SH. [77°]. Formed from the bromo-ethyl-imide and KSH at 100°. Converted bromo-ethyl-imide and RSH at 100°. Converted by NaOEt and glycollic chlorhydrin into syrupy C_nH₁O₂:N.C₂H₁,S.C₂H₁OH, whence POCl₃ forms C₂H₁O₂:N.C₃H₂,S.C₄H₄DI [70°], while POBr₄ forms C₃H₄O₂:N.C₄H₃S,C₄H₄Br [90°]. Reacts with C₃H₄O₂:N.C₄H₄Dr and NaOEt, forming (C₄H₄O₂:N.C₄H₄Dr [129°], which is oxidised by braining water, to the corresponding subsocial bromine water to the corresponding sulphoxide [191°], and by chromic acid to the sulphone [256]. Iodine in alcoholic solution forms (C₈H₁O₂:N.C₂H₁)₂S₂ [139°], whence B"H₂Cl₂ [203°] (Gabriel, B. 24, 1122, 3098).

n - Propyl - imide C₈H₁O₂:NPr. (283°). Crystals (Gabriel, B. 24, 3105).

Isopropyl · imide [85°]. (273°).

B · Bromo · propyl · imide

C_sH₁O₂:N.CH₂:CHBr.CH₃. [105°]. Formed from the allylimide and HBr (Seitz, B. 24, 2627). Converted by KSH into C,H,O,:N.CH,CHMe,SH [88°], which is oxidised in alcoholic solution by I to (C₈H₄O₂:N.CH₂.Cl1Me)₂S [161°]. Potassium sulphocyanide forms C,H,O,:N.CH,CHMe.SCy

γ · Bromo · propyl · imide C₈H₁O₂:N.CH₂CH₂CH₂Br. [73°]. Got from trimethylene bromide and potassium phthalimide methylene bromide and potassimi primarimae (Gabriel, B. 21, 2671; 23, 90). Needles (from ligroin). Converted by sodium ethyl-malonic ether into C₈H₁O₂:N.C₃H_a·CEt(CO₂Et)₂ [62°], and by sodium benzyl-malonic ether into C₈H₁O₂:N.C₄H_a·C(CH₁Ph)(CO₂Et)₂ [c. 110°] (Aschan, B. 23, 3692). Potassium sulphocyanide forms C₈H₄O₂:NC₃H₆SC₃ [98°].

Ethylene - di - imide $(C_8H_4O_2.N)_2C_9H_4.$ [232°]. Formed by heating potassium phthalimide with ethylene bromide at 200° (G.).

Butyl · imide C,H4O2:NC4H9. Formed by distilling cupric phthalyl-amido-hexoate (Reese, A. 242, 16). Tables (from dilute alcohol).

Isobutyl - imide C.H.O.: N.CH.Pr. [939]. Formed from isobutyl bromide and potassium phthalimide (Neumann, B. 23, 999). Plates.

Isoamyl · imide C,H,O,:N.C,H,11. (308°). Solidifies when strongly cooled (N.).

Allyl-imide C₄H₁O₄:NC₃H₂, Allyl-phthal-imide. [71^o]. (295^o). Tables. Yields a dichloride C₄H₁O₂:NC₄H₂Cl₄ [93^o], and a dibromide [114^o]. When nitrous acid is passed into its solution in cold benzene, and the product heated to 145°, there is formed C.H.O.NC.H.NO, crystallising in plates [178°] (Neumann, B. 28, 1000).

Acetonyl - imide C,H,O,:N.CH,Ac. [117°] Made by heating potassium phthalimide with enhoro-acetone at 120° (Goedeckemeyer, B. 21, 2684). Plates and needles. Gives rise to an oxim [172°] and also to a phenyl-hydrazide CH,C(N,HPh).CH,N:C,H,O, [152°].

Desyl - imide C,H,O,:N.CHP)Bz. [158°].

Desyl-inide C,H,O,N,CHPhBz. [158°]. Formed from phenyl bromo-benzyl ketone and potassium phthalimide (Neumann, B. 23, 994). Yellowish crystals, v. sl. sol. alcohol.

Phenyl-imide C₆H₁<CO>NPh. Phthalanil. [205°]. Formed by distilling phthalic acid (1 mol.) with aniline (1 mol.), and by heating phthalimide with aniline (Laurent; Doebner, 4. 210, 267; Pintti, B. 16, 1322); Michael a. Palmer, Am. 9, 202). Needles (from alcohol), insol. water. Converted by heating with BzCl and ZnCl₂, into C, H₂O₂N.C, H₃Bz [183°] (Deebner, A. 210, 267). The p-chloro, p-bromo, p-iqdo, and m-nitro-phenyl-imides of phthalic acid melt at 195°, 201°, 228°, and 243° respectively (Gabriel, B. 11, 2260).

Ben'zyl-imide C.H.O.:NCH.Ph. [116°]. Formed from potassium-phthalimide and benzyl chloride (Gabriel, B. 20, 2227). Needles (from alcohol). The o- and m-nitro-benzylimides melt at 219° and 155° respectively.

o-Cy ino-benzyl-imide C.H., C.O.; NCH., C., H., CN. [182°]. Prisms (from HOAc) (G.). The p-isomeride [184°] is converted into CO.H.C., H., CO.NH.CH., C., H., CO.H. [255°] by NaOHAq (Günther, B. 23, 1059).

Tolyl'-imides C_aH_cCO_aNC_aH₄Me. The o-, m-, and p-compounds melt at 182², 153², and 204² respectively (Michael, B. 10, 579; Piutti, A. 227, 205; Fröhlich, B. 17, 2679; Kuhara, Am. 9, 52).

m-Methyl-benzyl-imide C.H.:C.Q.:N.CH.C.H.Me. [118]

Formed by heating potassium phthalicaide with C.H.Me.CH.Br at 200° (Brömme, B. 21, 2700). White needles, v. sol. alcohol. The compound (C.H.;C.O.;N.CH.), C.H., [237°] is formed by using [1:3] C.H., (CH.Br),

ψ-Cumyl-imide C₁, H₁, NO₂ i.e. C₈H₄:C.O.:NC₈H₄Me₂. [148³]. (above 360°). Formed by heating phthalic anhydride with e-cumidine (Fröhlich, B. 17, 1802). Trimetric crystals. Converted by ammonia into the compound C₈H₄(CONH₂).CONHC₈H₂Me₈ [218°], crystallising in needles, while methylamine and allyl-anine yield the corresponding compounds C₈H₄(CONHMe).CONHC₈H₂Me₃ [215°] and

s.Tri.methyl-phenyl-imide C₅H₄:C₂O₂:NC₄H₂Me₃. Phthalmesidil. [171]. Got by boiling mesidine with phthalic anhydride (Eisenberg, B. 15, 1017). Silky needles (from alcohol), insol. water. Yields, on nitration, the compounds C₂H₁O₂:NC₂HMe₃(NO₂) [210²] and C₃H₁O₂:NC₆Me₃(NO₂)₂ [242²].

C.H. (CONHC, H.). CONHC, H. Me. [179°].

Isocymyl-imide C.H.O.;NC₁₀H₁,. [145°]. Formed by heating the anhydride with m-isocymidine (Kelbe a. Warth, A. 221, 169). Yields C.H.O.;NC.H.₁₂NO. [167°] on nitration.

Naphthyl-imides C.H.;O.O.;NO.H., The

Naphthyl-imides C₂H, C₂O₂:NO₃H, The (a)- compound [166°] (P.); [182°] (M.) and its (β)- isomeride [216°] are got by heating the corresponding naphthylamines with phthalic an-

hydride (Piutti, G. 15, 479; Maschke, C. C. 1886, 824).

Tri-nitro-phenyl-imide C₂H₄O₂N.C₄H₄(NO₂)₂. [259°]. From potassium phthalimide and pieryl chloride (Schmidt, B. 22,

3257). Stair-like groups of crystals.

o - 0.xy - phen yl - imide
C.H.; C.O.; NC, H., OH. Oxpphthalantl. [220°].
Formed by heating phthalic anhydride with
o-amido-phenol (Ladenburg, B. 9, 1528). Converted by sodium carbonate solution into
CO.H.C., H., CO.N.H.C.H., OH [223°].

p · Oxy · phenyl · imide. [288]. Got in like manner from p-amido-phenol (Piutti, G. 16, 252). Yields C,H.;CO.;N.C,H.;OAc [239] and CO.H.C,H.;CO.;NI.C,H.;OH [289]. HNO, forms C,H.;C.O.;NC,H(NO),OH [210], which yields an acetyl derivative [177].

m-Nitro-phenacyl-imide

C.H.O.:N.CH.CO.C.H.NO. [204]. Formed from the brome of the control of the control

Phenyl hydrazide C.H.;C.O.;N.HPh. [1782]. Formed from phthalyl chloride and phenyl-hydrazine in ethercal solution (Piakel, A. 232, 233). Yellow needles, insol. water, sol. hot alcohol and chloroform.

Hydrides of phthalic acid. When reduced by sodium-amalgam in a solution kept acid by HOAc phthalic acid yields trans (1, 2)-dihydride. Neutral sodium phthalate reduced by sodiumamalgam without addition of acid yields the stable (4,5)-dihydride (Baeyer, A. 269, 154; cf. Graebe a. Born, A. 142, 330). Phthalic acid, suspended in water, is reduced by sodium-ancalgam to a lactonic acid which yields a crystalline lactone [255°]; phthalide, and the (1,2)-dihydride are also formed. Both the (1,2)-dihydrides reduce aqueous AgNO₄ (sic) on warning, forming at once a black pp. Boiling aqueous cupric accetate gives off CO. and forms a white pp. which on addition of HOAc deposits Cu₂O. The which on addition of HOAc deposits Cu.O. The liquid contains benzoic acid (Baeyer, A. 269, 151). None of the other dihydrides of phthalic acid are attacked by cupric acetate. ammoniacal AgNO3 gives with: the (1,2)-dihydride a black pp.; the (4,5)- and (1,6)- dihydrides a brown pp.; the (3,6)-dihydride a white pp. not turning frown. The (1,2)-(1,6)- and (4,6)dihydrides give benzoic acid and CO₂ when feebly oxidised. The (3,6)-dihydride gives phthalic acid (Baeyer, A, 269, 179). The hoxahydrides are most stable, the tetra-hydrides next, and the dihydrides least stable (Baeyer, A. 269, 169). The cis anhydrides are more stable than the trans anhydrides. The trans acids are more stable than the cis acids. The anhydrides of the dihydrides are well crystallised, and yield the corresponding acids when boiled with water. The anhydrides are got by means of AcCl or Ac.O. The (1,2) dihydride will not stand AcCl. The (4,5)-dihydride needs long boiling with AcCl. Boiling Az₂O often changes the trans to the cis var ety. The anhydrides of the cis melt at lower temperatures than their trans isomerides (Baeyer, A. 269,

In the following hydrides the two carboxyls are in the positions 1 and 2. The small numbers following Δ indicate the position of \mathbb{Q}

atoms supposed doubly united to the adjacent | C atoms.

Trans. A^{8,5} or (1,2). di-hydrids. CH:CH.CO.H. [210°]. S. 16 at 10°; 6 at CH:CH.CH.CO.H. [210°]. S. 16 at 10°; 6 at 10°. Formed by reducing phthalic acid (20 g.) dissolved in NaOAc (32°8 g.) and water 200 c.c. at 0° by adding successive quantities of 3 p.c. sodium-amalgam (40 g.) and 50 p.c. acetic acid (6 c.c.), and finally adding H.SO. (Baeyer, A. 269, 189). Prisms (from hot water). Not reduced by sodium-amalgam in the cold. Lead acetate gives a flocculent pp., sol. HOAc.

Reactions.—1. Boiling NaOHAq changes it

entirely to the (4,5)-isomeride. Nine hours boiling with water does the same. - 2. KMnO. hot ammoniacal AgNO, and aqueous AgNO, at 100° are at once reduced .- 3. Aqueous cupric acetate forms a green pp., which gives off CO₂. On adding HOAc the liquid becomes clear and contains benzoic acid, Cu₂O being ppd.—4. Oxidised by boiling CuSO, to benzoic acid (Baever, A. 269, 191) .- 5. The acid takes up Br (4 at.) and the product is reduced by zinc-dust and HOAc to the original dihydride.-6. Combines with HCl, hence cannot be etherified by alcohol and HCl. -7. Combines with HBr (2 mols.) in aqueous solution at 100°. The product could not be crystallised, is reduced by sodium-amalgam to a hexahydride, while zinc and HOAc do not form an unsaturated acid.

Cis (1,2)-dihydride. [175°]. S. 18 at 10°. Does not accompany the trans form in the product of reduction of phthalic acid (Baeyer, A. 269, 192). The trans acid boiled with Ac₂O (but not AcCl) for 7 minutes is changed to the anhydride of the cis isomeride. The lead salt of the cis acid is insol. HOAc, while that of the trans acid is soluble therein. Large colourless many-faced prisms. Readily converted into anhydride by warming with Ac₂O. The anhydride [100°] crystallises from ether in colourless needles, and is re-converted into the acid by boiling water. The cis acid is converted into the (4,5)-dihydride by boiling NaOHAq, by 9 hours' boiling with water, and even (unlike the trans isomeride) by standing for 2 days with 15 p.c. NaOHAq. Reacts with silver and copper salts like the trans acid.

Δ^{2,6} or (4,5) - Dihydride. CH_CH:C.CO,H [215°]. S. ·8 at 25°; ·2 at 10°. Got by reducing phthalic acid (60 g.) with sodium-amalgam (1200 g.) (Baeyer, A. 269, 195; c. Astié, A. 258, 187). Lustrous triclinic crystals.

Reactions.—1. Not affected by evaporating with boiling NaOHAq, but by long warming with very cone. aqueous or alcoholic KOH it is partially changed to the A^{2,4} or (1,6)- dihydride.—2. Reduced by sodium-amalgam in a current of CO₂ at 100° to A' or (1,4,5,6)- and cis and trans A' or (1,2,3,6)-tetrahydrides.—3. KMnO₄ oxidises it to oxalic and phthalic acids (no succinic acid).—4. Alkaline K,FeOy, on boiling forms benzoic acid. Cold dilute H,SO₄ and MnO₂ also form benzoic acid.—5. PCl₃ gives phthalic anhydride.—6. Br in the dark forms C,H₂Br₂O₄ [185°].—7. With HBr (2 mols.) it combines forming crystalline di-bromo-phthalic acid bexahydride (Baeyer, A. 269, 198), which is re-

duced by sodium amalgam to phthalic acid trans-hexallydride. AcCl converts the acid into an anhydride [157°]. The silver salt boiled with water is reconverted into the (4,5)-dihydride. Alcoholic potash converts dibromophthalic acid hexallydride into the $\Delta^{2,4}$ or (1,6)-dihydride.

Methyl ether MeA'. (250°).

Anhydride [84°]. Got by boiling the (4,5) acid with AcCl (Baeyer, A. 269, 196). The product is evaporated over soda-lime and H₂SO₄ in vacuo, when the anhydride separates in large tables or prisms, sl. sol. ether, v. sol. chloroform. Hot water readily dissolves the anhydride, converting it into the parent acid. Na₂CO₂Aq forms an orange-red solution, which bleaches litmus as long as any anhydride is undissolved, the blue colour afterwards returning when all is dissolved. On adding H₂SO₄ to the solution a resin is ppd. Heating on the water-bath resinifies the anhydride, forming some phthalic anhydride,

Δ²⁴ or (1,6)-dihydride. CH CH_xCH.CO_xH [180°]. Formed by boiling the di-hydro-dibromide of the (4,5)- dihydride of phthalic acid CH_xCHBr.CH.CO_xH with a solution of KOH (1 pt.) in MeOH (2 pts.) for 1½ hours (Baeyer, A. 269, 199). Formed also in small quantity by heating the (4,5)- acid with conc. aqueous or alcoholic KOH or NaOH. Rosettes of prisms (from water). More soluble in water than the (4,5)-dihydride. Hot cupric acctate forms a white pp. which dissolves on cooling.

Reactions.—1. KMnO₄ and Na₂CO₂Aq form oxalic acid in the cold, and some phthalic acid. 2. Ammoniacal AgNO₃ forms a white pp. turning brown on warming.—3. Cold dilute H₂SO₄ and MnO₂ form benzoic acid and CO₂—4. Boiling alkaline K₄FeCy₈ also forms benzoic acid.—5. Converted by Ac₂O in the cold into the anhydride which crystallises from chloroform in cubes [104°] and is reconverted into the acid by warm water. The anhydride dissolves in Na₂CO₃Aq and bleaches litmus meanwhile. The anhydride is converted by heat into the anhydride of the (3,6)- dihydride.—6. Sodiumanalgam reduces it in the cold (difference from isomerides) to the cis-(1,2,3,6)- tetrahydride.—7. Combines with HBr (2 mols.) when heated at 100° with a solution of HBr in HOAc (Baeyer, A. 269, 200). The product [190°] crystallises from ether in plates, and is reduced by sodiumanalgam to the trans hexahydride.

Reactions.—1. When heated at 100° for a long time it is partially converted into anhydride. Evaporation of its aqueous solution also partially converts it into anhydride. The anhydride [185°] is also got by heating the acid with Ac.O. It crystallises in plates.

Readily sublimes in feathery plates. Does not bleach litmus .- 2. Sodium-amalgam does not reduce it even when gently warmed (Baeyer, A. 269, 205).—3. Dilute H.SO, and MnO. oxidise it to phthalic acid. Boiling alkaline K.FeCy, also forms phthalic acid.—4. KMnO, is at once depolarized.—5. Relians (10 no.) No.OMA (2000). colourised.-5. Boiling (10 p.c.) NaOHAq forms (4,5) and (1,6) isomerides.

A' or (3,4,5,6) - Tetrahydride CH₂CH₂CCO₂H [120°]. Formed by dissolving its anhydride in boiling water (Baeyer a. Astie, A. 258, 203; 269, 176). Got also by distilling the tetrahydride of pyromellitic acid (Baeyer, A. 166, 346). Monoclinic leaflets (containing aq). When heated at 100° for some time it melts, forming the anhydride. KMnO, oxidises it to adipic acid. Boiling conc. KOHAq changes it to the A' acid. Oxidised by Br and alkalis to di-oxy-phthalic acid hexahydride (tartrophthalic acid).-BaA" aq: crystalline pp.

Methyl ether Me,A". Combines with Br, forming two dibromides [84] and [124].

Anhydride C,H,O₃. [749]. Formed by heat-

ing the A2 acid or its anhydride at 215° for some time. Plates (from ether), v. sol. ether.

Δ² or (1,4,5,6). Tetrahydride CH₂CH₂CH₂CO₂H. (215°). S. 88 at 10° H.C.p. 881,600. H.F. 215,400 (Stohmann, J. pr. [2] 43, 540). Got by reducing a boiling solution of sodium phthalate with sodium-amalgam (Baeyer, A. 258, 175). Formed also, together with the trans A' isomeride, by reducing the (4,5)-dihydride in the same way. Prisms (from water). Bromine vapour yields a dibromide [225°]. MeOH and HCl form an oily methyl ether, which KMnO, yields a crystalline dibromide [74°]. oxidises it to oxalic and succinic acids

Anhydride CaH,O,. [79°]. Formed from the acid and AcCl. Prisms. Changed by heat into the anhydride of the A' acid.

Trans-A' or (1,2,3,6) - Tetrahydride сн.сн.сн.со.н сн.сн.сн.со.н [218°]. S. .145 at 6°. Formed, together with the (1,4,5,6)-tetrahydride, by reducing the (4,5)-dihydride in boiling solution by sodium-amalgam (Baeyer, A. 258, 210; 269, 161). Leaflets (from water). De-colourises KMnO, at once. Yields a methyl ether Me, A" [40°], which forms a dibromide [117°]. Anhydride C.H.O. [140]. Got from the acid and Accl. Needles (from ether). Changed by heat into the cis- isomeride.

Cis-A' or (1,2,3,6) · Tetrahydride
[174°]. S. 9 at 6°. Formed by adding sodiumamalgam at 0° to a solution of the Na salt of the (1,6)-dihydride in a current of CO₂ (Baeyer, A. 269, 202). Formed also by boiling the trans Δ^4 tetrahydride with Ac.O for 15 minutes. Large prisms. Boiling Ac.O forms the anhydride, which crystallises from ether in tables [59°].

Trans (or fumatoid) hexahydride C.H. (CO.H). [221°]. S. 23 at 20°. Formed by reducing the hydrobromides of the di- and tetra- hydrides with sodium-amalgam or with seine-dust and HOAc (Baeyer, A. 166, 350; 258, 214; 269, 161; cf. Mizerski, B. 4, 558). By reducing the (3,4,5,6)-tetrahydride in a hot solution a mixture of trans- and cis- hexahydrides is obtained. Leaflets (from water). May be

distilled unchanged if quickly heated, but yields the cis- anhydride when slowly heated. Not oxidised by cold squeous KMnO. Yields a dimethyl ether [83°], m. sol. ligroin.—PbA" aq:

Anhydride. [140°]. Formed from the acid and AcCl. Long needles (from ether). Changes when heated into the cis-isomeride.

Cis- (or maleoid) hexahydride. [c. 1920]. Got from its anhydride, which is formed by heating the anhydride of the trans- isomeride at 220° for eight hours. Short four-sided prisms, more soluble than the trans- isomeride. Not attacked by cold aqueous KMnO, Conc. HClAq at 180° changes it to the trans variety. The Ba and Zn salts are less sol. hot than cold water.

Anhydride. [32°].

Isophthalic acid [1:3] C_oH₁(CO₂H)₂. [c. 300°]. S. 013 at 25°; '22 at 100°. H.C.v. 769,100. H.C.p. 768,800. 11.F. 190,200 (Stoh-

mann, J. pr. [2] 40, 138).

Formation.—1. By exidising m-xylene with K.Cr.O, and H.SO, (Fittig a. Velguth, Z. [2] 8, 526; A. 148, 11; 153, 268).—2. By fusing sedium formate with potassium m-sulpho-benzoate (V. Meyer, A. 156, 265; 159, 1).-3. The ether is formed by the action of ClCO, Et and sodiumamalgam on m-di-bromo-benzene (Wurster, A. 176, 149) .- 4. By fusing potassium formate with potassium benzoate (Richter, B. 6, 876), mbromo benzoate (Ador a. Meyer, A. 159, 16), or di-sulpho-benzoate (Barth a. Senhofer, A. 159, 228). -5. By oxidation of m-toluic acid (Weith a. Landolt, B. 8, 715) .-- 6. By saponification of its nitrile .- 7. By heating the hydrides of prehnitic and pyromellitic acids with H,SO, (Baeyer, A. 166, 334; Suppl. 7, 4).-8. By strongly heating NaOBz (Conrad, B. 6, 1395) .- 9. By oxidation of colophony with dilute nitric soid (Schreder, A. 172, 93).-10. By the action of a hot aqueous solution of cuprous potassium cyanide upon m-diazo-benzoic chloride, and saponification of the resulting nitrile (Sandmeyer, B. 18, 1498).

Preparation.-m-Xylene is converted, by heating with bromine at 125°, into C_aH₄(CH₄Br)₄, which is boiled with alcoholic potash, and the resulting C.H. (CH.OEt), oxidised with chromic acid mixture (Kipping, B. 21, 46).

Properties.—Long slender needles (from water), m. sol. alcohol. May be sublimed.

Salts.—K₂A".—BaA" 6aq. Triclinic crystals (by spontaneous evaporation) (Lossen, A. 266, V. sol. water. BaA" 4aq? Needles (by cooling hot saturated solutions). - CaA" 2 aq:

needles.—Ag,h": amorphous pp.

Methyl cther Me,A". [65°]. Needles
(from dilute alcohol). H.F. 173,300 (Stohmann,

J. pr. [2] 40, 353).

J. pr. [2] 40, 533).

Diethylether Et, A". [0°]. (285°).

Diephenylether Ph, A". [120°]. Got by boiling the chloride with phenol. Long needles.

Chloride C, H. (COCl). [41°]. (276°).

Formed by heating the acid with PCl, at 200°

(Schreder, B. 7 708; Münchmeyer, B. 19, 1849).

Amide C.H.(CO.NH₂). [265°] (B. Beyer, J. pr. [2] 22, 351); [above 270°] (Luckenbach, B. 17, 1431). Got from the chloride and NH₂. Plates, al. sol. water and alcohol.

Nitrils C.H.Cy. [158°]. Formed by distilling potassium cyanide with potassium bens-

ene m-disulphonate (Barth a. Senhofer, A. 174, 236; Meyer a. Michler, B. 8, 672; Nölting, B.8, 1112; Luckenbach, B. 17, 1428), or with potassium m-chloro- or bromo- benzene sulphonate (Meyer a. Stüber, A. 165, 165; Limpricht, A. 180, 92). Formed also by heating the oxim of isophthalic aldehyde C.H.(CH:NOH), with excess of AcCl at 100° for a long time (Münchmeyer, B. 20, 508), by the dry distillation of calcium m-cyano-benzoate (Brömme, B. 20, 521). and by boiling an alcoholic solution of C, H, (CS.NH,), with an aqueous solution of lead acetate (Luckenbach). Small needles (from alcohol), insol. water, m. sol. ether. Converted by alcohol and dry HCl into phthalimido-ethyl ether C. H. (C(NH).OEt), [66°]. MeOH and HCl yield C. H. (C(NH).OMe), [c. 62°]; while mercaptan and HCl form C. H. (C(NH).SEt), which, like the two preceding bodies, forms a crystalline hydrochloride (Luckenbach).

Semi-nitrile v. m-CYANO-BENZOIC ACID. Tetrahydride of Isophthalic acid

C₆H_g(CO₂H)₂. [199°]. Formed by reduction of isophthalic acid by boiling its alkaline solution with sodium-annalgam (Baeyer, B. 19, 1806). Needles, v. sol. hot water.—Ag.A": white pp. Methyl ether Me.A". Oil.

Isomeride v. TEREPHTHALIC ACID.

References .- AMIDO-, BROMO-, BROMO-NITRO-, CHLORO-, IODO-, NITRO-, OXY-, and OXY-AMIDO-PHTHALIC ACIDS.

Homo-phthalic acid v. CARBOXY-PHENYL-ACETIC ACID.

Diphthalic acid v. DIPHTHALYLIC ACID.

PHTHALIC ALCOHOL v. DI-OXY-XYLENE.

PHTHALIC ALDEHYDE C₈H₆O₂ ie. **C.H.**(CHO), [1:2]. Mol. w. 134. [52²]. Formed by boiling C_aH₁(CHCl₂, (1 mol.) with NaOHΛq (4 mols.) (Colson a. Gautier, Bl. [2] 45, 509; A. Ch. [6] 11, 29). Formed also by oxidising C.H. (CH2.OH) (Hijelt, B. 19, 411). Solid, v. sl. sol, water. Coloured blue by NH Aq. Slowly oxidised by air.

Oxim C_dH₄(CH:NOH)₂. [2 needles (Münchmeyer, B. 20, 509). [215°]. Small

Isophthalic aldehyde C.H. (CHO). [1:3]. [90°]. Formed by boiling C₆H₄(CHCl₂)₂[1:3] with water (Colson a. Gautier, Bl. [2] 45, 509; V. Meyer, B. 20, 2005). Needles. Reduces silver solution with difficulty. Gives a violet-red tint with rosaniline reduced by SO₂. Oxidised by KMnO₄ to isophthalic acid.

Oxim C₆H₁(CH:NOII)₂. [212°] (Münchmeyer); [180°] (Meyer). Plates (from hot alcohol). Converted by AcCl at 100° into C₆H₄Cy₂. Yields the ethers C₂H₄(CH:NOMe)₂ [77°] and C.H. (CH:NOEt), [165°].

Reference. -OXY-ISOPHTHALIC ALDERYDE.

Isomerides. TEREPHTHALIC ALDEHYDE and PHTHALIDE

PHTHALIC ALDEHYDE ACID v. ALDEHYDO-BENZOIC ACID and PHTHALALDEHYDIC ACID.

PHTHALIDE C₈H₉O₂ i.e. C₆H₄< CH₂>O. Lactone of w-Oxy-o-toluic acid. [73°]. (290°

Formation. -1. By reducing phthalyl chlor-ide with zine and HClAq (Kolbe a. Wischin, C. J. 19, 339), or with Mg and HOAc (Baeyer, Z. [2] 5,399; 10,123,1445; 11,637). -2. Occurs among the products of reduction of phthalic an-

hydride by zinc-dust and HOAc (Wislicenus, B. 17, 2178). - 3. By passing bromine-vapour over o-toluic acid at 140° (Hjelt, B. 19, 412).

Preparation .-- Phthalimide (1 pt.) is reduced to phthalidene by means of tin (13 pts.) and HCl. The tin is ppd. by zinc, and sodium nitrate added to the filtrate. The yellow pp. of the nitrosamine of phthalidine is filtered off, washed, and heated with dilute NaOH. The phthalide is ppd. by HCl and distilled. Yield on the phthalic anhydride -70 p.c. of the theoretical

(Graebe, B. 17, 2599).

Properties. Needles (from hot water), sl. sol. cold water, v. sol. alcohol and ether. Does not combine with NaHSO, (Hessert, B. 11, 238), or reduce ammoniacal AgNO. Does not react with

hydroxylamine.

Reactions.-1. Oxidised by alkaline KMnO to phthalic acid. -- 2. Alkalis and alkaline carbonates form w-oxy-o-toluic acid, v. vol. iii. 781. - 3. Sodium-amalgam forms hydrophthalide C.H.O., a viscid mass, v. sol. alcohol and other, and also 'phthalylpinacone' CusHisO. [197°] .- 4. Ammonia on heating forms phthalimidine .- 5. Aniline at 210' forms phenylphthalimidine .- 6. Phthalic anhydride on heating forms diphthalyl.—7. KCy at 185° forms $C_aH_1(CH_a,CN),CO_2H_1$ [116°], which forms CaA'_2 2aq, and yields carboxy-phenyl-acctic acid ORA 2.201, and remarks on saponification (Wislicenus, B. 18, 172; 233, 112). KCy at 200° yields C₁₈H₁₁N₁O₃ (?) [240°-245°].—8. Boiling IIIAq forms o-toluic acid. 9. Br at 140° forms exo-bromo-phthalide. at 160° yields phthalyl chloride (Racine, A. 239, 79) .- 10. NaOEt acting on an ethereal solution of oxalic ether and phthalide forms an ether C12H10O5 [122°] crystallising from alcohol in needles, and forming with phenyl-hydrazine the compound $C_{18}H_{18}N.O.$ [1595] (Wislicenus, B. 20, 2062; A. 246, 342).

Phenyl-hydrazine compound C₁,H₁,N₂O₂i.e.CH₂(OH).C₄H₃,CO.N₂H₂Ph. [174°]. Readily formed by warming phthalide with phenyl-hydrazine for a few hours (Meyer a. Münchmeyer, B. 19, 1707, 2132; Wislicenus, B. 20, 401). Sol. hot water and alcohol, sl. sol. ether. Silvery needles. Partially resolved into the parent substances by fusion. Very unstable towards acids and alkalis. H.SO forms a colourless solution, turned raddish-violet by FeCl,

References. -- AMIDO-, BROMO-, CHLORO-, NITRO-, and OXY-PHTHALIDE.

PHTHALIDE CARBOXYLIC ACID v. Oxy-CARBOXYL-PHENYL-ACETIC ACID

PHTHALIDE SULPHONIC ACID

 $SO_3H.C_bH_4 < \stackrel{CH}{CO} > O$. Formed by warming phthalide with fuming H.SO, (20 p.c. SO, extra) (Hoenig, B. 18, 3453), Needles, v. sol. alcohol, insol. ether. - BaA'2 - CuA'2 2aq: light-blue prisms.

PHTHALIDINE is PHTHALIMIDINE. PHTHALIMIDINE Call, NO i.e.

 $C_{e}H_{i} < \frac{CH_{2}}{CO} > NH$. [150°]. (337°) at 730 mm. Formed by reducing phthalimide with tin and HCl, and by heating phthalide in a current of NH₂ (Gracbe, B. 17, 2598; 18, 1408; A. 247, 290; Barbier, C. R. 107, 918). Needles or prisms, sl. sol. cold water, v. e. sol. alcohol and other. Not volatile with steam. Oxidised by

KMnO₄ to phthalimide. Bromine forms C_{1e}H₂N₂O₂Br₃ [150°]. Distillation over zincdust forms phenyl-isoquinoline. Yields a nitroderivative $C_6H_4 < \frac{CH(NO_4)}{CO} > NH$ [210°], converted by oxidation

a di-nitro- derivative [195].

B'HCl. [150°]. verted by oxidation into phthalide. Yields also

Thin white needles, v. sol. water. $-B'_{*}H_{*}PtCl_{*} - B'_{*}HAuCl_{*}$. [176°]. $-B'C_{*}H_{*}(NO_{*})_{*}OH$. [140°]. $-C_{*}H_{*}AgNO_{*}$. Acetyl derivative C. H. AcNO. [151].

Needles (from dilute HOAc).

Yellow needles (from water or alcohol). Converted by NaOHAO inte verted by NaOHAq into ω-oxy-o-toluic acid, and by NaSH into thio-phthalide C.H.OS [60].

Reference.—DI-CHLORO-PHTHALIMIDINE. pseudo-Phthalimidine C, H, NO probably $C_{\bullet}H_{\bullet} < \stackrel{CH_{\circ}}{<} NH$. This compound is formed, as hydrochloride, by heating w-chloro o-toluylamide C_aH₁(CH₂Cl).CO.NH₂ to 150 160. The picrate B'C_aH₂(NO₂)₃OH forms a crystalline yellow pp.; the salt B'₂H₂Cl_PtCl, 2aq forms flat orange yellow needles (Gabriel, B. 20, 2231).

ISO-PHTHALIMIDO-ETHYL ETHER $[66^{\circ}].$ C,H,(C(NH).OEt), [1:3]. The hydrochloride is got by passing dry HCl into a mix-ture of isophthalic nitrile (1 mol.) and absolute alcohol (2 mols.) dissolved in benzene (Luckenbach, B. 17, 1431). The free base crystallises in small needles, v. sol. alcohol and other. It decomposes on heating into alcohol and isophthalic nitrile.—B"H.Cl., [270°]. Crystalline. PHTHALIMIDYL-BENZYL v. BENZYLIDENE-

PHTHALIMIDYL PROPIONIC ACID

PHTHALIMIDINE.

 $\mathbf{C}_{11}\mathbf{H}_{9}\mathbf{NO}_{3}$ i.s. $\mathbf{C}_{6}\mathbf{H}_{4} < \mathbf{CO.NH}_{2}\mathbf{CO.NH}_{2}$

[2257]. Formed by dissolving the dilactone of thenyl ethyl ketone dicarboxylic acid in NH,Aq (Roser, B. 18, 3119). Long yellowish needles, v.

sol. hot alcohol.—BaA'₂.—CaA'₂ laq.—AgA'.

Lactone C₁₁H₈NO₃. [c. 205°]. Formed by evaporating the dilactone mentioned above with conc. NH₂Aq on the water-bath. Small tables, v. sol. alcohol, sl. sol. cold water. Reconverted by boiling HClAq into the dilactone. Dissolves easily in cold aqueous alkalis, forming salts of a dibasic acid C, H, NO.

PHTHALONITRILE v. Nitrile of PHTHALIC ACID.

PHTHALOPHENONE v. DI-PHENYL-PHTHAL-WE.

o-Phthalophenone C,H,Bz, [1:2]. [146°]. Got by oxidising o-di-benzyl benzene (Zincke, L. 9,

31). Tables (from alcohol).

Sophthalophenone C.H.Bz. [1:3]. Phenylene
di-phenyl diketone. [100]. Formed by the
action of benzene and AlCl, on isophthalyl
chloride (Ador, B. 33, 320). Plates (from alcohol). Yields two dinitro- derivatives [200°] and [100°]?

[100°]?

Mono-oxim C.H., C(NOH), C.H., Bz. [201°]
(Nölting, B. 19, 146). Nodules, v. sol. alcohol.

Di-oxim (C.H., C(NOH)), C.H., [70°-55°]
(Münchmeyer, B. 19, 1849). Small crystals.

p-Phthalophenone C.H., Bz., [1:4]. Tere
**C.H., Bz., [1:4]. Tere
**C.H., Bz., [1:4]. [160]

phthalophenone. (a)-Di-benzoyl-benzene. [160]. Formed by oxidising p-di-benzyl-benzene with CrO₂ and HQAc (Zincke, B. 9, 31; Wehnen, B.

9, 309). Got also from terephthalyl chloride, benzene, and AlCl₁(N.). Plates (from benzene). PCl₃ yields C₂₀H₁₁Cl₄ [92°]. Sodium amalgam forms di-oxy-di-benzyl-benzene [171°].

Mono oxim. [213°]. Nodules. Dioxim. [235°]. Crystal.. PHTHALOXYL-AMIDO-ACETIC ACID

C₁₀H_aNO, i.e. CO₂H.C₆H₄.CO.NH.CH₂CO₂H. Giveocoll-phthaloptic acid. [106°]. Formed by the action of alkalis on phthalyl-amido-acetic acid (Reese, A. 242, 6; Gabriel a. Kroseberg, B. 22, 426). Six-sided plates (containing as).— 22, 420). SIX-Butta praces containing May.
A. A. K.A.: hygroscopic necdles. - BnA...
Ag.A.: plates, sl. sol. hot water.
PHTHALOXYL-AMIDO BENZOIC ACID

CO.H.C.H., CO.NH.C.H., CO.H. [277°]. Formed by exidation of the p-tolylimide of phthalicacid with KMnO, (Michael, B. 10, 576).

PHTHALOXYL AMIDO HEXOIC ACID CO.H.C. H. CO.NH.C. H. Mc.CO.H. Occurs in two varieties, the active [1327] and inactive [103], which are got by boiling the corresponding phthalyl-amido-hexoic acids with NaOHAq (Reese, A. 242, 20). Both acids are decomposed by boiling water into leucine and phthalic acid.

PHTHALURIC ACID v. Uramic acid of Ригиалле асто

DIPHTHALYL C, II,O, i.c.

C, H, CO, O, CO C, H, [335°].

Formation. 1. By heating phthalyl chloride with reduced silver at 150° (Ador, A. 164, 229). 2. By fusing phthalic anhydride with zinedust; and, together with other products, by reducing phthalic anhydride with zine dust and HOAc (Wislicenus, B. 17, 2178). 3. By heating phthalide with NaOAc and phthalic anhydride or thio-phthalic anhydride (Graebe a. Guye, B. 17, 2851; A. 228, 126; 233, 241). - 4. By boiling phthalaldehydic ether with alcoholic KCN (Goldschmidt a. Egger, M. 12, 60).

Properties .-- Needles, insol. water, v. sl. sol. alcohol and ether. May be sublimed in a current of CO... Combines with Br forming C₁₆H₈Br₂O₄ [c. 225]. PCl₃ at 160° forms the chloride C₁₆H₈Cl₂O₄ [245°]. Bromine and water at 100° form bromo-diphthalyl, which crystallises from benzene. Alkalis form diphthalyllactonic acid.

H_y tride C_{1.}H₁₀O₄ i.e.
C₀H₁(C_{0.0}, O.Co) C₀H₁ [229°] (W.); [250°] (Hasselbach, A. 243, 249), a product of the action of zinc dust and HOAc on phthalic anhydride (Wislicenus). Needles (from alcohol), v. sol. HOAc. Potash forms di-oxy-di-phenyl-ethane

dicarboxylic acid. References .- TEFRA-CHLORO-, NITRO-, and Oxy- Diphthalyl.

PHTHALYL-ACETIC ACID C, H,O, i.e.

-Ç:CH.CO.H. [c. 246°] (G.); [above $C^{a}H^{4} < CO^{\circ}Q^{\circ}$ 260°] (Roser, B. 17, 2620). Formed by boiling phthalic anhydride (10 pts.) with Ac O (20 pts.) and NaOAc (2 pts.) (Michael a. Gabriel, B. 10, 391, 1551, 2199). Formed also by dissolving acetophenone ow-dicarboxylic acid in H.SO. (Gabriel, B. 17, 2521). Needles (from nitrobenzene), insol. water, v. sl. sol. hot alcohol.

Reactions .- 1. Aqueous Na()H (1 mol.) forms a solution of its Na salt, but ercess of alkali con-

verts it into acetophenone ow-dicarboxylic acid. 2. Distillation in vacuo splits it up into CO₂.

and methylene-phthalide.—3. Bromine in HOAc
gives CBr₄.CO.C₆H₄.CO₂H [160°]. Dry Br gives
C₂H₄.O₂:CBr.CO₂H [c. 235°].—4. Chlorine acting on the HOAc solution forms CCl, CO.C, H, CO, H [144°].-5. H.SO, at 100° forms tri-benzoylenebenzene (v. vol. i. p. 485).—6. Ammonia gives rise to phthalimidyl-acetic acid C₁₀H,NO₃ i.e. -C:CH.CO₂H (?) which crystallises C'H' CO'NH from water in needles [c. 200°] and yields CaA', 2a, BaA', 4aq, and AgA' (Roser, B. 17, 2623; Gabriel, B. 18, 2451).—7. NMeH, Aq at 0° forms NHMe.CO.C, H, CO.CH, CO.H [145°], which is converted by concentrated H.SO, into C.H. CO.NMe [c. 212°], crystallising from alcohol in silky needles, split up by heat into CO2 and C8H. CO NMQ2, a crystalline mass which is converted by bromine-water into C₁₀H₁₀BrNO₂ [126°] (Gabriel, B. 18, 2453). 8. Cold H.SO. into C.H. CO.H. CO.H. [180] cold H2SO, into C4H4 CONEt -C:CH₂ (Merand by heat into liquid C_sH₄ CO·NEt

tens, B. 19, 2368).—9. Propylanine forms, in the cold, C_{1.1}H_{2.N}O₂ [103°], crystallising in prisms (M.).—10. Aniline at 100° forms C_{1.2}H_{1.2}NO₂ [192°], crystallising from benzene in cubes, converted by cold H.SO, into C_{1.3}H_{1.1}NO [265°] and by heating at 204°–230° into the isomeric C₂H₄ CO·NPh [100°] (Mortens, D. 19, 2371).—11. Secondary and tertiary amines have

2871).—11. Secondary and tertiary amines have no action.—12. Sodium-analgam forms the lactone of oxy-carboxy-phenyl-propionic acid (2. v.).

Salt.—AgC 10H,O.: amorphous pp. PHTHALYL-DIACETIC ACID

C.H. CO.O C(CH₂CO₂H)₂. [158°]. Formed by saponifying phthalyl-di-malonic ether with KOHAq (Wislicenus, A. 242, 80). Prisms.—BaA'2aq: prisms, v. sol. water.—Ag₂A''.

PHTHALYL-ACETOACETIC ETHER C₁₁H₁₂O₃

i.s. C₄H₄CO.0 C:CAc.CO₂Et. [121°]. Formed from sodium acotoacetic ether and phthalyl chlorido (Fischer a. Koch, B. 16, 651; Bülow, A. 236, 185). Prisms (from alcohol). Decomposed by H₂SO₄ at 65° into HOAc and phthalyl-acetic acid. Alcoholic KOH forms deliquescent crystalline K₂O₄H₄O₇. Phenyl-hydrazine acetate forms C₂₀H₄N₄O₄ [238°], which is reduced by zinc-dust and HOAc to carboxy-benzyl-acetoacetic ether [92°].

PHTHALYL ALCOHOL v. DI-w-OXY-O-

PHTHALYL-AMIDO-ACETIC ACID

C₁₀H,NO₄ i.e. C,H.;C₂O₂;N.CH₂CO₂H. Phthalyl glycocoll. [192³]. Formed by heating phthalia anhydride (2 pts.) with glycocoll (1 pt.) (Drechsel, J. pr. [2] 27, 418; Resse, A. 242, 1). Crystals (from water), decomposed by boiling HClAq into phthalic acid and glycocoll. Cold NaOHAq forms phthaloxy-amido-acetic acid (q. v.).—NaA'aq.—NH₂A'. [206³].—CaA',2aq.—CuA',3aq.—AgA'.

-Pt(N₂H₂A')₂. Colourless prisms; got by evaporating a solution of the acid with oxide of plato-diammonium.

Ethyl tther Eth'. [105°] (R.); [113°] (G.). (above 800°). Formed from Ag₂A" and Etl (R.), and also by heating potassium plthalimide with CH₂Cl.CO₂Et (Goedeckemcyer, B. 21, 2688; Gabriel, B. 22, 426). Needles, v. sol. benzene.

PHTHALYL. p. AMIDO. BENZENE SUL-PHONIC ACID C_sH.;C₂O₂:N.C_sH.;SO H. The Na salt, got by heating plthalic anhydride with sodium p-amido benzene sulphonic acid at 250°, crystallises from water in silky needles (Pellizzari, A. 248, 153; G. 18, 314). It is converted by boiling ammonia into phthalimide and sodium p-amido-benzene sulphonate. The Ba and NH₄ salts are also crystalline.

PHTHALYI. o. AMIDO BENZOIC ACID C₀H₁:C₂O₂:NC₆H₄.CO₂H₁ [217°]. Formed by heating anthranilic acid with phthalic anhydrid (Gabriel, B. 11, 2261). Prisms, sol. HOAc. Phthalyl-m-amido-benzoic acid. [276°] (G.);

Phthalyl-m-amido-benzoic acid. [276°] (G.); [282°] (P.). Formed from phthalic anhydride and m-amido-benzoic acid, and also by saponifying its ether [152°], which is formed by heating phthalic ether with m-amido-benzoic acid (Pellizzari, B. 18, 216; A. 232, 147). Needles. The amide is described in vol. i. p. 158.

Anilide. [209°]. Prisms (Piutti, B. 16,

PHTHALYL-AMIDO-ETHANE SULPHONIC ACID C₃H₄O₂:N.C.₂H₃SO₃H. Salt. — KA' ½aq. Formed by heating potassium amido-ethane sulphonate with phthalic anhydride (Pellizzari, G. 18, 324). Monoclinic crystals; aibic = 7:908:1:2·594; β = 60° 42′. Decomposed by alcoholic NH, into phthalinide and taurine.

PHTHALYL - AMIDO - HEXOIC

C₁,II₁,NO₄ i.e. O₈H₄O₂:N.CH(C₄H₉).CO₂H. [116°].

[a]_n = -21 97° in a 5 p.c. alcoholic solution at 22°. Formed by fusing leucine with phthalic anhydride (Recse, A. 242, 9). Needles, v. sl. sol. hot water. Laworotatory. Converted by distillation into an inactive variety [142°], which yields PtN,H₆A'₃A³₃aq. Conc. HClAq at 150° forms leucine and phthalic acid. NaOHAq forms phthaloxy-amido-hexoic acid (q, v.).—NaA'.—NII,A'. *[160°-165°].—PtN,H₆A'₃3aq.

PHTHALYL-AMIDO-NAPHTHALENE SUL-

PHTHALVI.-AMIDO. NAPHTHALENE SUL-PHONIC ACID C₄H₁:C₂O₂:N.C₁₀H₆:SO₃H. The salt KA'3aq is got by heating sodium (a)naphthylamine sulphonate with phthalic anhydride (Pellizzari a. Matteuci, G. 18, 321). It crystallises in needles, sol. water.

PHTHALYL-γ-AMIDO-n-PROPYL-MALONIG ETHER C,H.(C,O,:N.CH,-CH,-CH,-CH,(CO,Et),-(18°). Formed by the action of sodium malonic ether on the γ-bromo-propyl-imide of phthalic acid (Gabriel, B. 23, 1767). Monoclinic plates (from ligroin); α:b:c=3·260 il:1·644; β=81°4′. Converted into δ-amido-valeric acid by heating with HClAq at 190°.

Phthalyl-amido-di-propyl-malonic ether

Phthalyl - amido - di - propyl - malonie ether C_sH₁O_z:N.OH_zCH_zCH_zCPr(CO_zEt)_z. [57°]. Formed in like manner from propyl-malonio ether (Aschan, B. 23, 3698). Prisms, insol.

water, v. sol. alcohol and ether.
DI - PHTHALYL - DI - AMIDO - QUINONE
C.H., N.O., s.c. C.H., O.(N.C.O.; C.H.), Fi.2:46].
[2777]. Prepared by heating tri-amido-pheno

hydrochloride with phthalic anhydride, dissolving the resulting C.H.(OH)(N.C.O.;C.H.), [above 800°] in potash, and treating the product C.H.(OH)(NH.CO.C.H., CO.H.), [above 300°] with intric acid (S.G. 148) (Piutti, G. 16, 254). Yellow needles (from HNO₃). Forms a compound [174°] with phenyl-hydrazine. IL,S passed into its solution in dilute HOAc forms crystalline C.H.,(OH),(N:C.O.;C.H.),, not melted at 310°. PHTHALYL-AMIDO-SUCCINIC ACID

C₁₇H₂NO₄ i.e. C₂H₄O₂:N.CH(CO₂H).CH₂CO₂H. [225°]. Formed by heating aspartic acid with phthalic anhydride for 1 hour at 180° (Piutti, G. 14, 473; 16, 2). Tufts of prisms (from water). Decomposed into phthalic and aspartic acids by heating with HClAq. Boiling aniline forms aspartic acid and the phenylimides of phthalic and phthalyl-amido-succinic acids. Diphenylamine forms three di-phenyl-amic acids C₄H_{O2}:N.C₂H₃(CONPh₂)(CO.H) [180°], [204°], and [194°]; the first and third crystallises with aq, and all three yield a salt AgA' and are decomposed by potash-fusion into aspartic acid, phthalic acid, and diphenylamine.

Salt .- CuA', 4aq : blue prisms.

C.H.O.N:CH CH.CO. Phonylimide [264°]. Formed from the acid and aniline.

Small needles (from HOAc), nearly insol. alcohol.

Tetra-phenyl-diamids
C_hH,O₂:N.C₂H₃:C₂O₂(NPh₂)_x. Two isomerides,
[273°] and [286°], are got by heating the acid with diphenylamine for 5 hours at 1903. Both are split up by HClAq at 200° into phthalic acid, diphenylamine, and aspartic acid.

PHTHALYL CHLORIDE v. Chloride of

PHTHALIC ACID.

PHTHALYL-ETHANE v. Anhudride of PHENYLOETHYL KETONE O-CARBOXYLIC ACID.

Di-phthalyl-ethane C18H10O, i.e.

-С:СП.СН:С— 0.0 О.СО С.Н. C'H' < CO'O Ethine-di-

phthalyl. [above 350°].

Formation.—1. Together with other products by the condensation of phthalic anhydride with succinic acid (Gabriel, B. 10, 1559; 19, 837).-2. By the action of conc. H.SO, upon di-phenyl ethylene diketone di-o carboxylic acid C,H,(CO,H),CO,CH,CH,CO,CH,(CO,H), or its ether .-- 3. By further elimination of H.O from the (a) or (B) anhydrides $C_{18}H_{12}O_{3}$ of the latter acid (Roser, B. 17, 2770; 18, 3115).

Properties. — Yellow needles (from nitro-benzene), insol. water and alcohol. By boiling with alkalis it is converted into di-phenyl ethylene diketone di-o-carboxylic acid. Nitrous acid forms C18H10N2O8 a crystalline body decomposing

at 160°, and converted by boiling HOAc into C₁₁H₂NO₆ [c. 240°].

Isomeride C₁₈H₁₈O₄. Formed as a by-product in preparing the preceding body by heating phthalic anhydride with succinic acid and NaOAc. Red needles with green lustre, not melted at 280°. Insql. water and alcohol, v. sol, hot aniline and nitrobenzene. Weak acid, forming unstable violet salts.

PHTHALYL-ETHYL-HYDROXYLAMINE v. vol. ii. p. 740. PHT#ALYL-HYDROXYLAMINE e. vol. ii.

p. 788.

C_{1e}H_{1e}O_s i.e. Diphthalia DI-PHTHALYLIC ACID CO.H.C.H., CO.Co.C.H., CO.H. (?) Diphthalic acid. [272°]. Formed by oxidation of diphthalyl (Ador, A. 164, 236), of (β)-dinaphthyl-diquinone $C_{20}H_{10}O_4$ (Korn, B. 17, 3021), and of di-phenylethane dicarboxylic acid (Dobreff, A. 239, 68). Formed also by the action of alcoholic potash on diphthalyl dibromide (Graebe, A. 228, 132; 242, 221). Minute tables, almost insol. water, alcohol, and ether. Converted by boiling conc. KOHAq into phthalic acid. Dilute NaOHAq at 110° forms di-phenyl-carbinol tricarboxylic acid. Reduced by HI to (CO.H.C.H.), C.H. Alcoholic hydroxylamine hydrochloride forms, on heating, C₁₈H₁₈NO₅ [152°] and C₁₈H₈N₂O₄ [286°]. Salts: BaA" 2uq: plates.—Ag₂A".

Methyl ether Me, A". [192°]. Formed from Ag, A" and MeI. Lemon-yellow plates. By passing HCl into a hot solution of the acid in McOH there is formed a colourless isomeric body [278°], partially converted into the methyl ether by heating with McOII at 200°, and split up by HClAq at 150" into diphthalylic acid and MeCi.

Ethyl ether Et.A". [155°]. Got from Ag.A" and Etl. Lemon-yellow needles. The colourless is omeride [174°] is formed by ethylation with alcohol and HCl.

Anhydride C₁₆H₈O₅. [165°]. Formed by heating the acid with Ac.O at 200°. Crystals (from HOAc), v. sol, chloroform.

DIPHTHALYLIMIDE C, II, NO, i.e.

 $C_{u}H_{i} < \overline{C(NH),O,O,CO} > C_{u}H_{i}$? [above 360°].

Got by warming di-phthalyl-lactonic acid with NII,Aq and by heating phthalimidine with NaOAc and phthalic anhydride or phthalimide at 220° (Graebe, A. 228, 137; 233, 246). Needles (from HOAc) forming a yellow solution in NaOHAq.

DIPHTHALYL-LACTONIC ACID C, H12O, i.e. -- Ç:C(OII).C₄H₄.CO₂H C'H'< Diphthal-

aldehydic acid. Formed by warming diphthalyl, in an atmosphere of H, with alcoholic potash (Graebe a. Schmülzigang, A. 228, 126; cf. Ador, A. 164, 229). Crystals (from alcohol). When heated for some time at 220° it splits up into water and diphthalyl, which then melts above 300°. When quickly heated it decomposes at 235°-240° with partial fusion. Conc. H₂SO₄ converts it into diphthalyl. Its alkaline solution is yellow, but becomes colourless through absorption of atmospheric oxygen, yielding diphthalic acid.

PHTHALYL-MALONIC ETHER C, H, Ot, i.s. C₀H₄CO.0 S. (ether) 7.1 C:C(CO₂Et)₂. [75°]. S. (ether) 7.1 at 9°; 58.8 at 35°. One of the products of the action of phthalyl chloride on sodium malonic ether (Wislicenus, A. 242, 23). Triclinic prisms (from ether), v. sol. alcohol.

Reactions. -1. Decomposed by long boiling with water into phthalic acid and malonic ether. 2. Hot potasa forms malonic and phthalic acids. A solution of caustic potash at 0° forms

C.H. CO.O. C(OH).CK(CO,Et), whence acids liberate oily 'phthalyloxymalonic' ether, which

malonic ether .- 3. NaOEt forms the compound ! C(OEt).CNa(CO2Et), crystallising in prisms, v. e. sol. water, yielding the cupric salt Cu(C₁,H₁₀O₂)₂2aq and, on adding an acid, oily C₁,H₂₀O₂. The dry salt, NaC₁,H₁₀O₂ is converted by EtI at 100° into oily C₁,H₁₀EtO,, upon which alcoholic potash reacts forming the salt ---C(OK) CEt(CO2K)2 ppd. as very de-

liquescent plates on adding alcohol to its aqueous solution, yielding amorphous, Ag, C, H,O,, and splitting up on acidification into ethyl-malonic acid and phthalic acid.—4. Zinc-dust and HOAc yield o-carboxy-benzyl-malonic ether (v. vol. i. p. 705).-5. Alcoholic NH, forms the diamides of malonic and phthalic acids .- 6. Sodium-malonic ether forms yellow C22H21Na2O101 decomposed by boiling water into phthalyl-dimalonic ether, malonic ether, and phthalic acid.

 $C_{\sigma}H \swarrow^{CO.O} \ ^{\bullet}$ Seminitrile

-- C:CCy.CQ.Et [c. 175°]. Formed from phthalyl chloride and sodium cyano-acetic ether in dry Et O (Muller, C. R. 112, 1140). White substance, sol. benzene.

Phthalyl-di-malonic ether $C_{22}H_{26}O_{10}$, i.e. -C(CH(CO₂Et)₂)₂· [49°]. Formed from

sodium-malonic ether and phthalyl chloride (Wislicenus, A. 242, 23, 80). Prisms (from

containing C22H24K2O10, which separates as orange

needles (containing 2aq) when Et,O is added to

alcohol), insol. water. Reactions .- 1. Potash forms a yellow solution

a solution of the other in alcoholic potash. Boiling aqueous potash forms phthalyl-diacetic acid C12H10Oa [158°] .- 2. Alcoholic NaOH forms. in like manner, lemon-yellow C22H21Na2O10 2aq, decomposed by hot water into malonic and phthalyl-dimalonic ethers and sodium phthalate. EtI at 100° converts the Na derivative into C₂₂H₂₄Et₂O₁₀, which yields ethyl-malonic ether on boiling with water.—3. The di-sodium derivative C₂₂H₂₁Na₂O₁₀ is converted by treatment with Ac₂O, phthalic anhydride, or phthalyl chloride into 'phthaloxy-dimalonic ether' C22H24O, or C₂H₄ CO.C(CO₂Et)₂ (?), S. (alcohol) 57 at 14°, which crystallises from ether in needles melting at 117° when slowly heated and at 106° when quickly heated. 'Phthaloxy-dimalonic ether' is also one of the products of the action of phthalyl chloride on sodium malonic ether (Wislicenus, A. 242, 28, 61). It forms a yellow solution with aqueous K₂CO, and KOH. Alcoholic potash forms C22H25KO10, which is the monopotassium derivative of phthalyl-dimalonic ether. Zinc-dust and HOAc reduce 'phaloxy-dimalonic

ether' to oily C<sub>2.H₂₈O₃.

PHTHALYL-PROPIONIC ACID C₁₁H₈O₄ i.e.</sub> C.H. CO.O. [245°-248°]. Formed by boiling phthalic anhydride (5 pts.) with propionic anhydride (10 pts.) and sodium propionate (1 pt.) for 45 minutes (Gabriel a. Michael, B. 11, 1013, 1679). Slender needles. Converted by boiling KOHAq into phenyl ethyl

ketone o-carboxylic acid. Reduced by sodiumamalgam to C.H. -CH.C,H,.CO,H [140°] which yields BaA', and AgA' and is converted by boiling baryta-water into oxy-carboxy-phenylbutyric acid CO_H.C.H.CH(OH).C.H.CO.H. H,SO, at 100° forms C, H, O, [237°].

Salt .- AgA': white powder. Amide C, H,O,NH, [195°]. Leaflets.

PHYCITE v. ERYTHRITE.

PHYLLIC ACID $C_{:2}H_{6i}O_{16}$ (?). [170]. S.G. 1.014. Extracted by alcohol from the leaves of the cherry-laurel, apple, almond, and elder (Bougarel, Bl. [2] 28, 148). Crystalline granules, decomposing at 180°. The K salt crystallises in needles, sl. sol. water, sol. alcohol.

PHYLLOCYANIN v. CHLOROPHYLL.

PHYSALIN C, H, H, O, Occurs in the leaves of the winter cherry (Physalis Alkekengi), from which it may be extracted by chloroform (Desaignes a. Chautard, J. Ph. [3] 21, 24). Yellowish amorphous powder, with bitter taste, v. sl. sol. cold water and ether, v. sol. alcohol. Softens at 180°, and decomposes at a higher tempera ture. Sl. sol. acids, m. sol. NH₃Aq. Salt.—Pb₄(C₁₁H₁₅O₅)₂O₂: white pp., got by adding Pb(OAc)₂ and NH₃Aq to the alcoholic solution.

PHYSETOLEIC ACID C10 H30O2. [30°]. Occurs in sperm oil, and is perhaps identical with hypogwic a id (Hofstüdter, A. 91, 177). Stellate groups of needles. Not affected by nitrous acid.

BaA'2: crystals, sol. hot alcohol.

PHYSICAL METHODS USED IN CHE-MISTRY. The object of this article is to present a general account of the chief physical methods of inquiry which are made use of in attacking chemical questions. In each section of the article it has been sought to lay down the principles of the method discussed, and to present, in a general way, the more important results that have been obtained. No section claims to give a complete account of the subject with which it deals. The following articles, which are not specially referred to in their alphabetical positions in the present article, should be consulted: Aggregation, States of, vol. i. p. 87; ATOMIC AND MOLECULAR WEIGHTS. vol. i. p. 336; CHEMICAL AND PHYSICAL PRO-PERTIES OF BODIES, CONNECTIONS BETWEEN, vol. i. p. 730; Densities, relative, vol. ii. p. 370; Dissociation, vol. ii. p. 385; Molecular con-STITUTION OF BODIES, vol. iii. p. 410.

I. CAPILLARITY, METHODS BASED ON. The term 'capillarity' is given to that property of bodies which is the cause of the rise of liquids in narrow tubes, the spherical shape of raindrops and soap-bubbles, the spreading of oil on the surface of water, and many other pheno-

The generally accepted theory by which these phenomena are connected and explained is due mainly to Laplace, and rests on the assumption that the parts of a body are held together by attractive forces which are insensible except at very small distances. We have evidence of the existence of these forces in the cohesion of bodies, in the latent heat of evaporation, which is merely the energy that has to be supplied to separate the parts from each other, and in the fact that at high pressures, when the parts of which a gas is composed are so near together that they never get altogether away from each other's influence, the compressibility is found to be greater than is required by Boyle's law. Though Laplace made no reference to molecules it is now usually supposed that the attractions in question are the forces acting between the molecules.

Imagine a molecule of a liquid surrounded by a sphere, whose radius is the distance at which the force ceases to be sensible. If the molecule is so far from the surface of the liquid that this sphere is entirely immersed, it will be on an average equally attracted all round, and no work will have to be expended to move it, but if it be so moved that part of the sphere is outside the surface, there will be a resultant force tending to draw it back again, so that to bring a molecule into the surface requires an expenditure of work. Now if we distort a given volume of liquid so as to increase its surface we bring i more molecules into the surface, and we increase the potential energy of the liquid by an amount proportional to the increase of surface, or the total potential energy arising from this source is proportional to the extent of surface. Hence, since in the position of equilibrium of any system the potential energy is a minimum, the liquid will of itself assume such a shape that the rurface is as small as possible consistently with other conditions, such as the action of gravity.

It is plain that what has been said is not restricted to liquids, but applies equally to solids and to the surface separating two different In the latter case a molecule at the surface of separation is acted on by both media. but unless the attractions are equal there will be a resultant force acting on it, and it will have potential energy by virtue of its position.

Capillary phenomena are often regarded as due to the external film of the substance being in a state of tension. It is not easy to imagine a tension at the surface of a solid, but the conception leads mathematically to the same results as the assumption of the existence of surface energy, and is practically only another way of stating the same thing, for we have seen that on the hypothesis of molecular attractions we arrive at the result that the surface tends to become a minimum, and this is equally well

described by saying that it behaves as though it were in a state of tension. Further, the measure of the tension - that is, the total force acting across a line of unit length-is numerically equal to the potential energy per unit area, which is easily proved as follows. Imagine a rectangular piece of the surface a cm. long and b cm. wide increase it to a rectangle a' cm. long and b cm. wide. Then we have produced (a'-a)b sq. cm. of new surface, and if E is the potential energy per sq. cm. we shall have done E(a'-a)b units of work. On the other hand, if T is the surface tension, the force acting on the side b will be Tb. and we have moved it through a'-a cm., and hence have done Tb(a'-a) units of work. These two measures of the work must be equal, and hence E = T; and since the rectangle can be taken anywhere on the surface and with its sides in any direction, it follows that the surface tension is the same at every point and in any direction.

It is to be observed that this tension differs from that of a stretched piece of indiarubber, for instance, in the fact that it does not depend on the amount of stretching. No matter how much a soap film is extended, the tension remains the same until the film becomes so thin that there are only a few molecules in the thick-

The surface tension, then, is a consequence of the molecular attractions which tend to draw the molecules as close together as possible. In order to balance this tendency and to allow the substance to be in equilibrium, Laplace imagined the existence of an internal hydrostatic pressure. which, from the value of the latent heat, is calculated by Stefan to be about 1300 atmospheres in the case of water. The potential energy due to this pressure is proportional to the volume, which is constant in most capillary phenomena, and hence has no effect on the equilibrium position.

The forms of crystals are probably conditioned to some extent by capillary forces. Most of the properties of crystals being different in different directions, the potential energy of a surface may be expected to depend on its direction, and those faces will be formed which have least energy. Further, as a large crystal has less surface in proportion to its volume than a small one, the familiar phenomenon of the large crystals absorbing the small ones is explained by the loss of potential energy resulting from the operation (v. Liveing, Camb. Phil. Trans. 14, 370).

If two immiscible fluids are in contact with a solid, the surface separating them meets that of the solid at a constant angle, called the angle of contact. The most important case is where one of the fluids is air and the solid is glass. Many experiments have been made to determine this angle, the conclusion being that in most Magie (W. 25, 429), Quincke (W. 27, 219), and Worthington (P. M. [5] 20, 65).

The constant which is most commonly used is the surface tension as defined above, but Quincke and some others use another called the specific cohesion, denoted by a2, which is twice the surface tension divided by the density of the liquid, or the height to which the liquid

would rise in a tube of unit radius.

The following are the principal methods that have been used in determining these constants: 1. By determining the rise of liquids in capillary tubes (Quincke, P. 139, 8; Frankenheim, J. pr. 23, 401).-2. By weighing or measuring the drops from a rod or pipette (Quincke, P. 135, 621; Duclaux, A. Ch. [5] 13,76; Linebarger, Am. S. 44, 83) .- 3. By measurement of large drops or bubbles (Quincke, P. M. [4] 41, 245; Eötvös, W. 27, 448; Worthington, P. M. [5] 20, 51).—4. By determining the force required to detach a disc or ring from the surface of a liquid (Weinberg, Z. P. C. 10, 34).

Mendeleeff states as one of the characteristics of a perfect liquid that its surface tension should be a linear function of its temperature, and Selby (P. M. [5] 81, 430) has given thermodynamical reasons for this relation. The subject has been investigated experimentally by Frankenheim, Weinberg, and others, and it is found that the equation $\gamma = a - bt$ holds approximately, where γ is the surface tension, t the temperature, and a and b are constants; hence by determination of y at two temperatures we can calculate roughly the

temperature $\frac{a}{b}$ at which the surface tension is

zero-that is, the critical temperature. Eötvös extends this result by showing that the rate of change with temperature of γv^{\dagger} , where v is the molecular volume of the liquid (and hence yv) is proportional to the energy of the amount of surface which contains a given number of molecules), has a constant value which is the same for all liquids.

The only measurements of the surface tensions of pure liquids which have been carried out extensively are those of Schiff (A. 223, 47; and G. 14, 368). Schiff determined the surface tensions of a large number of organic substances at their boiling-points, and divided the observed values by the molecular weights, denoting the quotient by N. This quantity was found to be in general unchanged by the substitution of one carbon atom for two hydrogen atoms, of one oxygen for three hydrogens, and similarly for other elements, so that each atom had its hydrogen equivalent, and compounds with the same total of hydrogen equivalents gave the same value for N. Taking N for ordinate, and x, the total hydrogen equivalent, for abscissa, Schiff plotted a curve from which he obtained the rela-

 $\log N = 2.8155 - .00728x - \log x.$ This equation enables us to calculate the surface tension of a liquid compound from its formula.

There are many exceptions to the law that each atom has a fixed hydrogen equivalent. For instance, C must be put equal to 3H in the free fatty acids instead of 2H as in most compounds; Ol generally has the value 7H, but when several chlorine atoms are attached to different carbons in a compound it has the value 6H; Br is usually equivalent to 13H, but sometimes to 11H, and so on.

A few preliminary measurements of the capillary constants of the surface separating water and organic liquids which do not mix with it, have been made by Linebarger (Am. S. 44, 83), by allowing the liquid to drop through the water, upwards or downwards, according to its specific

gravity, and counting the drops from a given volume. The results already published show that the introduction of two methyl groups in the meta- position into a benzene ring does not affect the surface tension, while if they are in the para-position the surface tension is greatly diminished.

· The surface tension of an aqueous solution of a salt is greater than that of water, and increases proportionately to the amount of salt present. Quincke (P. 160, 337, 560) found that for solutions of chlorides of equivalent concentrationsthat is, containing the same amount of chlorine per c.c.—the constant of proportionality is the same; but Volckmann (W. 17, 353), on repeating the work, concluded that the agreement is not within the errors of experiment. Traube (J. pr. [2] 31, 192) showed that the capillary constant of a 10 p.c. solution of water in alcohol is not raised, like that of water, but is lowered, by the presence of a dissolved salt.

Determinations of the surface tensions of solutions of organic substances in water have not hitherto led to any important general laws. Such substances lower the surface tension but not proportionally to the concentration, as appears from the work of Duclaux (A. Ch. [5] 13, 76), and of Traube (B. 17, 2294; J. pr. [2] 31, 177; 34, 292). The former gives the law that if aqueous solutions of two alcohols, or of two acids, have the same surface tension, the percentage compositions of the two solutions will have a constant ratio. Traube's work confirms this result, but leads to nothing farther of interest beyond the fact that solutions of isomerides have not generally the same surface tensions.

J. W. C. rally the same surface tensions.

II. CRYSTALLOGRAPHIC METHODS; v. CRYSTALLISATION, vol. i. p. 278; and Isomorphism,

vol. iii. p. 88.
III. DIALYSIS AND DIFFUSION, ME-THODS BASED ON. When a solid is dissolved in a solvent a movement of the particles occurs from the places where the solution is more concentrated to the places where it is less concentrated, and continues until the concentration is uniform throughout. Similarly when gases which do not react chemically are mixed, movements of the particles take place until the gases are equally distributed throughout the space. The mixing of gases or liquids, by reason of the movements of their particles, is called diffusion. When the diffusion of a liquid is accompanied by a total or partial separation into unlike bodies, the process is generally called dialysis; this process is usually effected by allowing the diffusion to take place through an animal or vegetable membrane. The chemical applications of diffusion are chiefly connected with the diffusion of substances in solution, and generally in solution in water.

Graham (T. 1850. 1, 805; 1851. 483) was the first to measure the rates of diffusion of different compounds, in aqueous solution, without a separating membrane. He nearly filled glass jars with the various solutions, carefully poured water on the top of the solutions, placed the jars 'n glass dishes, and filled these with water until the water extended in the dishes about 3 c. above the tops of the jars. The dishes were set aside for some time; when the process was to be stopped. glass plates were slid over the mouths of the jars,

which were then removed, and the quantities of substance in the liquids outside the jars, called the diffusates by Graham, were determined.

the diffusates by Graham, were determined. Graham found that the quantities which diffused varied much according to the compositions of the diffusing substances. The quantity of a specified substance which diffused in a determinate time was found to be nearly proportional to the concentration of the original solution. Graham also found that diffusion was able to effect a tolerably complete separation of two salts whose rates of diffusion differed considerably. He looked on his results as showing that nearly equal quantities of chemically similar salts diffused in equal times.

A few years after Graham's fundamental experiments, Fick, reasoning from Fourier's theory of the conduction of heat, came to the tentative conclusion that the quantity of a salt which diffuses through a stated area is proportional to the difference between the concentrations of two areas infinitely near one another. Assuming the truth of this statement, a definition was obtained for the diffusion-constant of a salt as the quantity of a salt which diffuses through unit area in unit time, when unit difference of concentration prevails throughout unit distance. A long series of researches by Belstein (A. 99, 165), Simmler a. Wild (P. 100, 217), Stefan (W. A. B. 79, 161), and especially by Weber (W. 7, 469, 536) and Graham (T. 1861, 183), has fully confirmed Fick's law, and has given measurements of the diffusion-constants of many substances. Attention should be drawn, in this connection, especially to Graham's method of allowing salts to diffuse in water gelatinised by starch, gum, &c. (T. 1861. 183; v. also Voigtländer, Z. P. C. 3, 316). In 1880, Long (W. 9, 613) made a number of determinations of rates of diffusion; he divided the numbers obtained by the molecular weights of the salts used, and thus obtained figures which represented the number of molecules of each salt which diffused under the same conditions. The results showed somewhat regular arrangements of the molecular diffusion-values. For instance, Long found that the haloid compounds of K had nearly the same value, that the sulphates of Mg, Zn, Mn, Co, Ni, and Cu had approximately equal values, and so on.

Marignac (A. Ch. [5] 2, 546 [1874]) followed up Graham's observations on the simultaneous diffusion of pairs of salts, and arrived at the important result that the order of the rates of diffusion of the salts of any acid is independent of the nature of the acid, and that the order of the rates of diffusion of the salts of a metal is independent of the nature of the metal. Marignac was thus able to construct a table showing the order of the diffusion-coefficients of acid radicles, on the one hand, and of metals, on the other hand. The table is as follows:—

CI, Br, I
NO, CIO₃, CIO₄, MnO₄
CrO₄
SO₄
CO₅
CO₆

H
K, NH₄
Ag
Na
Ca, Sr, Ba, Pb, Hg,
Mn, Mg, Zn
Cu
Al

Crystalloids and colloids. Graham observed that the rates of diffusion of different substances

differ much. He found certain substances which diffused in water with very great slowness; these substances included gums, tannin, albumen, caramel, &c. Inasmuch as the substances which diffused comparatively rapidly generally assumed crystalline forms when they solidified, while substances which diffused very slowly solidified in amorphous forms, Graham called the former crystalloids and the latter colloids. The solution in water of crystalloids is usually accompanied by thermal changes: the solution; boil and freeze at temperatures different from the boiling- and freezing-points of water, and the properties of the solutions differ considerably from those of the solvent. On the other hand, the solution in water of a colloidal substance is not attended with any marked changes.

The solution of a colloidal substance allows the diffusion through it of a crystalloid, in solution, but scarcely permits the diffusion of another colloid. If, then, a solution containing a crystalloid and a colloid is separated from water by a colloidal membrane, such as animal or vegetable parchment, the crystalloid will diffuse through this membrane into the water outside, but the colloid will be retained in the interior liquid; in this way colloids can be separated from crystalloids by diffusion; this process was called dialysis by Graham.

By means of dialysis, Graham prepared many compounds in a colloidal, or jelly-like form (T. 1861. 183). Most inorganic colloidal compounds were found to exist in two forms; one soluble in much water, and the other gelatinous and insoluble in water. For instance, an aqueous solution of silicic acid, containing 14 p.c. of this acid, was obtained by adding a solution of sodium silicate to excess of dilute HClAq, and dialysing (by pouring into a flat saucer formed of parchment paper which was floated on pure water) for some days, until the liquid inside the dialyser ceased to give a reaction with AgNO, Aq; the liquid in the dialyser was then concentrated by boiling in a flask. The solution of silicic acid gelatinises after a few days, or at once by addition of a trace of an alkaline or earthy carbonate, or by a few bubbles of CO₂, or by certain soluble colloids, such as gelatin or soluble alumina. The gelatinised colloidal silicic acid is insoluble in water.

Graham prepared soluble and gelatinised colloidal forms of Al₂O₃, Fe₂O₃, Cu₂FeCy₈, Cr₂O₃, stannic acid, &c. Other soluble inorganic colloidal compounds have been obtained in recent years.

Graham looked on colloids as very different in their constitution from crystalloids. He regarded colloids as prone to undergo changes which take place very slowly; he thought it possible that the molecule, or molecular aggregate, of a colloid is formed 'by the grouping together of a number of smaller crystalloid molecules.' Colloids, a sording to Graham, are capable of loosely combining with various proportions of water; this process of 'gelatinous hydration' was regarded by Graham as being 'as truly chemical as that of crystalline hydration.'

Graham's views on the nature of colloids have been confirmed, on the whole, by more recent work. J. M. van Bemmelen has especially studied the hydration of colloids. He gives the name hydrog. Is to those gelatinous hydrates which contain varying quantities of water not agreeing with any definite formula; he describes the reactions of hydrogels with gases and liquids to form what he calls absorption-compounds, and discusses the part played by such compounds in the soil (L. V. 35, 69; Abstract in C. J. 54, 985). For van B.'s work on various individual colloids v. R. T. C. 7, 37, 69, 75, 87, 106, 114; Abstracts in C. J. 54, 1157, 1162.

4-31-62

Picton (C. J. 61, 137) and Picton a. Linder (C. J. 61, 114, 148) have recently prepared a number of soluble colloidal forms of metallic sulphides, such as CuS, HgS, As.S. colloidal solutions were obtained (1) by pouring solutions of the metallic salts into H. SAq, into which H2S was continuously passed, and dialysing, after removal of excess of II.S by a current of H; (2) by passing H2S into water with metallic hydrates in suspension; (3; by suspending freshly ppd. metallic sulphides in water and passing in H.S. · All the solutions contained combined H2S, and were therefore solutions of hydrosulphides. The solution of As, S, contained about 6 g. As, S, per litre, and that of HgS about 10 g. per litre. These colloidal solutions were shown to contain solid particles. In some cases the particles were visible through a powerful microscope; in other cases the particles were proved to be present by passing a ray of bright light through the liquids, and showing the scattering of polarised light which thus occurred. Solutions of 'colloidal molybdic acid.' and colloidal silicic acid containing free HCl. seemed to be free from solid particles. Solution of colloidal antimony sulphide showed no particles under the microscope, but the presence of particles was revealed by the passage of a beam of light; after keeping for about ten days, par-ticles had formed sufficiently large to be seen by the help of the microscope; and after some weeks the Sb was all ppd. as Sb.S₃. In this case the passage could be followed from a liquid containing very minute particles, whose presence was detected only by the fact that they scattered light, to a liquid containing particles sufficiently large to be seen under the microscope. On the other hand, a solution of CrCl, in water containing a little chromous acetate was able to scatter light, and therefore contained solid particles; but after a few days the particles were no longer present. In this case the passage could be traced from a liquid containing very minute particles to a liquid free from such particles.

The colloidal solutions did not diffuse, with one exception—namely, arsenious sulphide. The diffusible solution was obtained by running As,O,Aq into H₂SAq, into which H₂S was continuously passed, and removing excess of H₂S by a current of H. This solution showed no particles under the microscope, but as it scattered polarised light particles were present in it. The liquid was put into a small wide-mouthed bottle, which was placed in a beaker and covered with water; a distinct amount of As,S, had diffused in one day, and after eleven days about 12½ p.c. of the As,S, was found in the diffusate. This colloidal solution therefore presented the interesting phenomenon of a liquid containing solid particles capable of scattering polarised

light from a beam passed through, and yet able to diffuse in exactly the same way as true solutions undergo diffusion.

Picton a. Linder consider that their experiments establish 'a good prima facie case for the belief that there is a continuous series of grades of solution passing without break from suspension to crystallisable solution.' They look on the very small particles in some of these colloids solutions as large molecular aggregates, and they think that these aggregates become very small in the solutions which can diffuse, and that the forces by which the aggregates are held in solution 'become more definitely those of chemical attraction.' (In connection with colloidal solutions v. Paterno, Z. P. C. 4, 457; and Barus a. Schneider, Z. P. 6. 8, 278.)

Diffusion of gases. The fact was observed by Dalton (P. M. 24, 8) that if a heavier gas is placed in a bottle which is connected with another bottle containing a lighter gas, and placed beneath the first bottle, after some days the gases will be equally mixed in both bottles. The same fact was observed, and some measurements were made, by Berthollet (Mém. S. d'A. 2, 463). Graham (Q. J. S. 1829, 74; P. M. 1833. 175, 269, 351) made a great many measurements of the rates of diffusion of different gases. For most of these he employed a diffusiometer, which consisted of a glass tube about 20 cm. long and about 11 cm. diameter, having a plug of plaster of Paris in one end extending inwards about ½ cm., and graduated from this end downwards. The tube was filled with the gas under examination and placed in water; when the level of the water in the tube had become constant, the total volume of gas now in the tube was measured, and the amounts of air and original gas contained in the tube were determined. With gases lighter than air there was a decrease in the contents of the tube, as the lighter gas passed out through the porous plate more quickly than air passed in; with gases heavier than air there was an increase in the gaseous contents of the tube, as air passed in more quickly than the heavier gas passed out.

The conclusion which Graham arrived at was that 'the diffusion or spontaneous intermixture of two gases in contact is effected by an interchange in position of indefinitely minute volumes of the gases, which volumes are not necessarily of equal magnitude, being, in the case of each gas, inversely proportional to the square root of the density of that gas.'

Modifications in Graham's apparatus have been made, and many determinations of the rates of diffusion of gases have been conducted; the results have fully confirmed Graham's law, which may be stated in the form $c:c' = \sqrt{d}': \sqrt{d}$, where c and c' are the diffusion rates of two gases whose relative densities are d and d'.

It is evident that Graham's law of diffusion gives a means for finding the molecular weights of gases; inasmuch as the law enables measurements to be made of the relative densities of gases, and the density of a gas, referred to hydrogen, multiplied by 2 is (approximately) the molecular weight of that gas. For a description of an instrument for this application of the law of diffusion v. Bunsen's Gasomet. Methoden, p. 160.

IV. DYNAMICAL METHODS. Several methods used in attacking chemical problems may be put together under this general title : v. CHEMICAL CHANGE, vol. i. p. 731; AFFINITY, vol. i. p. 67; AGGREGATION, STATES OF, vol. i. p. 87; DISSOCIATION, vol. ii. p. 385; EQUILIBRIUM, CHE-MICAL, vol. ii. p. 434; MOLECULAR CONSTITUTION or Bodies, Theories of, vol. iii. p. 410.

V. ELECTRICAL METHODS.

Historical .- The history of the science of electricity divides itself into two well-defined periods, the boundary between which lies at the close of the last century, and is marked by Volta's discoveries concerning the production of electricity when different substances are brought into contact. The investigations in the older period, when only the phenomena of frictional electricity, characterised by small quantity and high tension, were known, showed no connection with chemical problems. It is true, Deimann and Paets van Trostvijk had decomposed water by means of the electrical machine; this effect was, however, assigned as due more to the high temperature of the electric spark than to a specific property of electricity.

It is only with Galvani's discovery of the electricity which appears when different substances are brought into contact, and with the scientific investigation of this discovery by Volta, that the period of electro-chemistry begins. This branch of science is thus of nearly exactly the same age as the current century. It was by means of the pile as constructed by Volta that chemical changes were recognised to be essential phenomena concurrent with the passage of an electric current through certain substances. . Directly this apparatus became known, Nicholson and Carlisle (1800) used it for the decomposition of water, and since then the fact that there is a close connection between chemical and electrical phenomena has always been present to the mind of investigators. The mysterious and unexpected mode of action of this apparatus soon revived the hope that by means of it the problem of vital activity might be fathomed. Consequently, the electric current was made to pass through various animal fluids, such as blood, protein, &c., with the object of following the changes produced by this influence, and thus obtaining information concerning the processes taking place in the organism. It was found that, along with other effects, a basic reaction was always observed at one pole, and an acid reaction at the other. On further investigation it was found that the acid and the base still appeared. even when water was taken instead of the animal fluids, and thus the electric current seemed to be a means for producing acids and bases from pure water. This is the point at which the classical researches of Humphry Davy began. In order to decide whether acids and bases were really produced from pure water by means of electricity, he repeated the experiments. He soon recognised that the vessels in which the water was contained exerted a determinant influence on the results; he proved that very small quantities of the substance of the vessels were always dissolved by the water, and that vessels of glass, clay, basalt, &c., were subject to this influence. The electric current had the power of decomposing the very small quantities of saline matter

present into acids and bases, and of accumulating these at the poles, where they could be detected ensily. Only ressels of gold proved to possess the necessary resistance, and when these were used not the least quantity of either acid or base was obtained from pure water.

After Davy had thus become acquainted with the great power of decomposing compounds possessed by the electric current, he proceeded at once to submit the most diverse substances to its influence. By means of the large batteries of the Keyal Institution, which had been constructed according to his plans, he succeeded in obtaining great effects; he decomposed the alkalis, and isolated the metals potassium and sodium.

At the present day it is difficult to imagine the impression which this discovery made on his contemporaries. It was not scientific circles only that were full of it; the public at large and the daily press occupied themselves most diligently with this fact. Everyone who could procure some dozens of copper and zinc plates tried to repeat the experiment, and gave an account of it. Napoleon, who then had just nearly reached the zenith of his power, proceeded at once to have larger batteries constructed in order to smooth the way for similar discoveries by the French scientists. He also offered great prizes for scientitic works dealing with voltaic electricity.

Davy's discovery was of great importance for the development of the science of chemistry, because it enabled the alkalis to be classed with other basic metallic oxides. Chemical classification was thus simplified considerably. The investigations of Davy were, however, without influence on the knowledge of chemical affinity, sound as were the views held by this man of genius concerning the relation between chemical and electrical processes.

It was at this same time that the two Swedish naturalists Berzelius and Hisinger carried out work which then, it is true, did not attract anything like the same attention as had justly been aroused by Davy's investigations, but which had an even more lasting influence on the later development of scientific chemistry. Davy's experiments dealt chiefly with the fact that the electric current split compounds into their constituents, and aimed at the isolation of these constituents. Berzelius and Hisinger went a step farther; they tried to grasp the laws underlying this decomposition, and from these they developed a theory concerning chemical compounds. The generalisations under which Berzelius and Hisinger comprised their results were as follows:

(a) Chemical compounds are decomposed by the electric current, and their components collect at the poles.

(b) The combustible substances, the alkalis, and earths go to the negative pole; oxygen, the acids, and oxidised substances go to the positive

The fact that Berzelius had experimented chiefly on the salts of the alkalis determined the theoretical conception of electrolysis. Since acids and bases appeared at the poles when alkali salts were electrolysed, acids and bases were considered to be the components of salts. Berzelius assumed further that a similar binary division prevailed throughout the whole domain of chemical compounds. He conceived every atom as endowed with a definite quantity of positive or negative electricity, and this led him to distinguish between positive and negative elements, and to arrange the elements in a series, beginning with the most positive down to the most negative. It was thus that for Berzelius the combination of elements with each other was simply an act of electrical attraction; according to him the thermal and optical effects which are produced along with chemical combination are due to the same cause as the corresponding plienomena which accompany the electric spark. It is true that at this point Berzelius, with the caution peculiar to him, himself brings forward the objection that when the opposite electricities have neutralised each other a further cause of their keeping together is no longer present. It seems, however, that he did not consider this difficulty of sufficient importance to give up his theory for it.

When a positive and a negative atom interact, their electricities, according to Berzelius, are in general not completely neutralised, as the quantities of electricity present differ according to the nature of the atoms. The compound formed thus retains a surplus of positive or of negative electricity, and acts therefore similarly to an element, but less intensely. It is in this way that compounds can again combine with each other to form compounds of a higher order, and so on, and thus is brought about a binary

constitution of all compounds.

This electro-chemical theory of Berzelius, which he developed more fully at a later time, has exerted a very marked influence on the progress of chemistry, since it has impressed on this science the form which was the only one recognised from 1810 to 1840. It was characteristic of this phase that after this first investigation Berzelius did not again undertake any experimental work on the action of electricity on chemical compounds. The places wherein the Berzelian theory was weak from the physical point of view were not considered at all, as the theory was used only for the purposes of chemical classification; no attempt was made to explain by means of it the problems of chemical affinity.

After an almost uncontested reign of twenty years' duration the theory of Berzelius proved itself insufficient to follow the progress of the science. Since it was deduced from the phenomena of the decomposition of compounds by electricity, it was not surprising that it could not represent the chemical relations of organic compounds, which, as a rule, are not decomposed by electricity. Investigations on this subject proved more and more conclusively that in chemical compounds individual atoms could be substituted by other atoms or groups of atoms, quite independently of the 'electro-chemical' nature of the elements; in the most conspicuous and best-known examples it was a question of the substitution of 'positive' hydrogen by 'negative' chlorine. Such a process Berzelius considered to be quite impossible in the light of his theory.

But it was not this proposition of the electro-chemical theory alone, but the whole foundation of Berzelius's system, which was made doubtful and proved to be untenable by the newer development of organic chemistry. The

theory of the binary constitution of chemical compounds was no longer capable of being brought into accord with facts, which rather led to the unitary conception of substances. Closely connected with this development is the establishment of the conception of the chemical molecule, a conception which assigned a sharply-defined existence to the combinations of the elementary atoms, and which led to the view that these structures would split up in the most diverso ways, according to the nature of the influences to which they were subjected, although no such division appeared pre-existing in the molecule.

At the same time (after 1840) at which purely chemical facts had proved Berzelius's system insufficient for the domain of organic chemistry, the insufficiency of its physical foundations was also made apparent. This happened in consequence of Faraday's funda-

mental work.

A lively discussion concerning the cause of the production of electricity in the galvanic pile had been carried on ever since the days of Volta. While Volta and his successors sought for the cause of the electric tension at the extremities of the pile in the contact of the metals, a number of other workers held to the opinion, as first expressed by Fabbroni, that the cause of galvanic electricity was to be found in the chemical processes which take place in the pile. It is not possible to enter here into the history of the contest which has lasted up to the present day. Faraday attempted to solve the problem, and in so doing he discovered the electrolytic law (1834) which goes by his name.

This law affirms, firstly, that when electricity passes through a body which is decomposed by it—that is, through an electrolyte—the quantity of substance decomposed is proportional to the quantity of electricity that has passed through. Secondly, the law affirms that when the same quantity of electricity passes through different electrolytes, the quantities of the different substances which are thereby decomposed are to each other in the ratio of their chemical equiva-

lents.

These two generalisations primarily supported the chemical theory of galvanic electricity, as according to them a galvanic current is never possible without a corresponding chemical process. At the same time, however, they were in unresolvable contradiction to the foundations of the theory of Berzelius as conceived by him; since, if one and the same quantity of electricity is always necessary in order to decompose chemically equivalent quantities of any substances, it cannot be true that different quantities of electricity cause their combination, in which act they neutralise each other. Berzelius was keenly alive to this contradiction, but as he did not wish to doubt his own theory he preferred to doubt the laws of Faraday, and he continually argued against them.

It was through the work of Daniell (T. 1839. i. 07, and 1840. i. 209), which followed up the researches of Faraday, that the electro-chemical theory was fought on the very ground from which it had sprung. The results of the electrolysis of neutral salts, such as potassium sulphate or sodium chloride, when, the two elec-

trodes of the electrolytic cell were separated by a porous diaphragm, showed that detonating gas (or hydrogen) was formed in the same quantity as in a voltameter with dilute sulphuric acid inserted in the circuit, and besides this an equivalent quantity of the salt was decomposed into acid and base. This phenomenon cannot be brought into accordance with the law of Faraday otherwise than by assuming that electrolysis does not split up the salts into base and acid, but rather into the metals and into the elements (such as Cl) or radicles (such as SO₄) combined with these. Thus, when potassium sulphate is electrolysed, hydrogen and oxygen are only secondary products, just as the free acid and the base are only secondary products; the salt K2SO, splits up rather into free potassium K, which acts on the water, forming potash (K2+2H.O = H2 + 2KOH), and into the radicle SO4, which with water gives sulphuric acid and oxygen $(SO_4 + H_2O = H_2SO_4 + O)$. Correspondingly, when copper sulphate is electrolysed we obtain, not copper oxide and sulphuric acid, but on the one side metallic copper, and on the other side SO, which gives sulphuric acid and oxygen. Thus Daniell arrived at the conclusion that the conception of salts as consisting of base and acid would have to be given up, and that they rather consist of a metal and a simple radicle (Cl, S, &c.), or a compound radicle (SO, NO, &c.), and he further pointed out that Davy had already expressed similar ideas.

The same result to which the application of Faraday's law led in this case had meanwhile been arrived at by chemical methods. Graham (T. 1833, ii. 253) had reduced the differences exhibited by the salts of phosphoric acid to differences in the amounts of water held by the acid, and had thus founded the theory of the polybasic acids, Liebig (1838), in his celebrated paper (A. 26, 113), enunciated the theorem that all acids must be looked on as hydrogen compounds, and that the formation of salts consists in the replacement of this hydrogen by metals or metallic radicles. By means of this conception the unnatural division between the salts of oxyacids on the one hand, and the halogen compounds of metals on the other, was again put aside. The necessity for such a division had been felt by Berzelius to be a great trouble, and to do away with it he had for long clung tenaciously to the assumption that the halogens were

oxygen compounds.

The first attempt to utilise the facts of galvanism for chemistry had failed. In 1850 Berselius's electrochemical theory had but few supporters left. Still the consciousness survived that the mistake had lain in the form in which the relation between chemical and electrical properties had been represented; and it continued to be recognised that this relation actually did exist, and that it was of the greatest importance. A sign of this recognition is found in the fact that although Berzelius's theory had been rejected, the elements which form bases were still called positive and those which form acids were called negative. In fact, the electrochemical contrast of the two constituents of salts is a fact which becomes obvious with each electrolysis, and which, therefore, cannot be doubted. It was only necessary to modify the view of Berzelius YOL IV.

and to say that it is not the acids and bases for more correctly their anhydrides) which are the constituents of salts, but rather it is the metal and the acid radiole. This modification of the electrochemical theory has, however, scarcely left any traces in the development of the chemistry of that time. The reason of this is that compounds of the nature of salts receded quite out of the foreground of interest. Organic chemistry, which at that time developed brilliantly dealt with substances very few of which could be decomposed by the electric current, which were not electrolytes, and for which, therefore, the electrochemical contrast did not exist. unitary conception was consequently involuntarily extended to the salts, and the important distinction between electrolytes and non-electrolytes was not at all taken into account by chemists. It is true that Faraday attempted to account for these two classes of bodies by supposing that in the one case the number of positive and negative atoms was the same, but in the other case these numbers were different; but this rule proved to be incorrect, and for a long time these relations were neglected because they could not be grasped scientifically. After the refutation of the erroneous views of Berzelius. people thought themselves justified in altogether ignoring the electrochemical relations.

This was the condition of electrochem.stry till quite recently. The only attention it received was from the hands of some physicists, and it is only natural that purely chemical problems did not fare particularly well under these circumstances, the more so as even up to the present day it often happens that from this side the electrolysis of dilute sulphuric acid is represented as the electrolysis of water 'which has been made conductive by an addition of sulphuric acid. Although the direct furtherance thus given to chemistry was insignificant, yet the indirect effects were important. If it is possible to speak to-day of the development of a new electrochemical theory, it is almost exclusively to these physicists that we owe the means for so doing.

The first investigator to be mentioned at this point is Hittorf. He connected his work with the experiments of Daniell, and took up the consideration of a phenomenon which had remained incomprehensible to the latter. Daniell experimented with sulphuric acid in his apparatus, he found that besides the electrolysis of the acid a change in the concentration had occurred; at the negative pole the acid solution had become more dilute, at the positive pole it had become more concentrated. It occurred to Hittorf that this phenomenon must be due to the different velocities with which the two constituents or ions of sulphuric acid-that is, 2H and SO,-travel through the liquid. If, for instance, the hydrogen remained at rest and the group SO, alone moved, it would follow that after the electrolysis of one molecular weight of sulphuric acid, there must be an increase, by that amount, in the concentration at the positive pole towards which SO, had travelled. If, on the other hand, the hydrogen alone travelled, the concentration would remain unchanged. Now, it had been found by Daniell that the increase in concentration at the positive pole was equal to less than a quarter of the quantity of soid electrolysed; the necessary conclusion was, therefore, that both ions travelled, but that 80, moved much more slowly than 2H. Hittorf proved by a great number of careful experiments (P. 89, 177; 98, 1; 103, 1; 106, 337) that this conclusion always agreed with observed facts. He then used the knowledge thus gained to answer chemical questions, for the solution of which no other means existed at the time. But in spite of their great importance, Hittorf's results have been all but completely ignored by shemists.

These experiments afforded verification of the conclusion that the more immediate components of salts - or what is the same, the ions of saltsreally are the metal and the acid radicle. At the same time electrolysis furnished Hittorf with the means of solving certain old problems. Thus, for instance, opinion was divided as to whether potassium platinichloride and similar salts should be considered as double salts—for example, as 2KCl and PtCl,-or as salts of chloroplatinic acid H,PtCl. Hittorf submitted sodium platini-chloride to electrolysis. If it consisted of 2NaCl + PtCl,, it followed that sodium and platinum were the positive ions and chlorine the negative; if, on the other hand, it was Na PtCl, the ions would be 2Na and PtCl.. In the first case, therefore, the platinum must travel to the negative pole, in the other case to the positive. Experiment decided for the latter view: the platinum did not go to the negative pole, as the metals generally do, but travelled with the chlorine to the positive pole, thus proving itself to be a constituent of the acid radicle. In a like manner Hittorf decided quite a number of similar questions.

During these investigations, Hittorf drew attention to another point, which at a later time proved to be of the utmost importance. The fact that electrolysis can be started by the weakest currents is in contradiction to the usual chemical views, according to which the constituents of salts, such as KCl, Na,SO, &c., are held together by very strong affinities. At the same-time, Hittorf emphasised the fact that those substances which conduct electrolytically are the most ready to interchange their constituents. This fact also is against the assumption of a specially firm binding together of the constituents of salts. Occasion will be found later to refer to this remark.

There are other parts of the science of electricity, besides the phenomena of electrolysis, in which the chemical nature of substances has to be considered. These are the electrical conductivities of electrolytes, the electromotive force of galvanic cells, and galvanic polarisation. These fields have been cultivated till quite lately only by physicists to whom purely chemical questions were foreign.

The electrical conductivity of an electrolyte is a quantity the determination of which was formerly attended with great difficulties. These difficulties occur because the ions which separate where the electric current enters or feaves the liquid 'polarise' the electrodes, and thus produce new and unknown electromotive forces. Details of the various attempts which have been made to overcome this difficulty will be given later. It was, however, only in 1880 that, after long and varied preliminary investigations, F. Kohl-

rausch (W. 11, 658) indicated a really practical and accurate method. As soon as the values of the electrical conductivities of electrolytes could be determined easily, by Kohlrausch's method. important relations soon came to be recognised between the conductivities and the chemical properties of electrolytes. The most important of these relations, the discovery of which was made by Arrhenius (Bigh. Swensk. Ak. 8, Nos. 13 and 14, 1884), lies on the path opened up by Hittorf. The fact that substances capable of conducting the current and of being electrolysed are also specially capable of entering into chemical reactions, which was emphasised by Hittorf, can now be made definite by saying that both powers are nearly proportional for different electrolytes.

From this discovery there has grown a new electrochemical theory, which, in its entirety,

will be expounded later on.

The other problem concerning the connection between the electromotive force of galvanic cells and the chemical processes within them was solved by Helmholtz (Die Erhaltung der Was solved by Heinmonz (Lee Market, 1847), and later on also by Sir William Thomson (P. M. December, 1858), and this was done primarily on the basis of a hypothetical assumption. According to Faraday's law, when equivalent quantities of different substances are used in the galvanic cell, equal quantities of electricity are always put into motion. being so, the intensity of the motion, or the electromotive force of the galvanic cells, must be proportional to the quantity of heat produced by the chemical processes within the cell. The supposition is made here that all heat is used for electrical work-a supposition which Thomson found verified by an experiment of Joule. Meanwhile it has been proved, however, that the heat produced in chemical changes is not generally completely transformed into electrical work, and Helmholtz (B. B. 1882) himself has worked out the formula representing the general relation between these two quantities.

To these problems are joined those concerning the nature and the value of galvanic polarisation. In this province investigation has, however, made so little way as yet that it suffices to point out that most important problems here await their solution.

The foundations of the science of electricity. General considerations.—If a bar of perfectly pure or amalgamated zinc is placed in dilute sulphuric acid, no chemical action takes place, nor is there any such action if a bar of platinum be introduced into the acid. But as soon as the two metals are made to touch each other an action occurs; the zinc is transformed into zinc sulphate by expelling the hydrogen from the sulphuric acid, which hydrogen, however, is evolved at the surface of the platinum bar.

Direct contact of the two metals is not necessary. If, for instance, the zinc is touched with the end of a copper wire and the platinum is souched with the other end, the same effect is produced. On the other hand, there is no effect if the connection is made through glass, wood, or sight like substances.

The copper wire which connects the two metals has acquired special properties which remain as long as the chemical action of the tulphuric soid on the sine lasts. If the wire is held parallel to a movable magnetic needle at a short distance above it, the needle will be deflected; further, the wire becomes heated; and finally, if the wire is cut in one place, and the two ends are placed close to each other on a paper moistened with solution of potassium iodide and starch, it can be perceived that a chemical decomposition of the potassium iodide has occurred, since a blue spot of iodide of starch appears under one end of the wire.

Work, or speaking generally, energy, is gained by the chemical action between the zinc and the sulphuric soid; the energy usually appears in the form of heat. The arrangement described shows that it is possible to conduct this energy away from the place where it is set free—that is, from the point of contact between zinc and sulphuric acid—and to make it effective at any point of the connecting wire we please. And further, we can obtain this energy at will in the form of thermal energy, chemical energy, or mechanical energy.

The sole difference that can be perceived between the metals in their usual state and when dipped into the acid is that they have become electric; the platinum shows itself charged with positive, and the zinc with negative, electricity. By means of a suitable electrometer this electric charge can be measured. It appears to be dependent on the nature of the metals, as well as on that of the acid.

Hence we conclude that the chemical action between the zinc and the acid does not, as usual, give out its energy in the form of heat, but in that of electrical energy. As to whether the transformation from chemical to electrical energy is complete or partial, and, if the latter, by what this partial amount is determined, these are questions with which we can occupy ourselves only at # later stage.

As is generally the case with all forms of energy, electrical energy allows itself to be resolved into two factors, one of which is a capacity, and the other is an intensity. For these factors the general law holds, that a system can be in a state of rest only if the intensity of the energy is the same throughout the whole. An exception to this occurs only if different kinds of energy are present simultaneously in one system; then there can exist a difference of one intensity, if a compensation is produced by a corresponding difference of the after intensity.

The two factors of electrical energy are called quantity of electricity and electromotive force or potential; the first is the capacity, the second the intensity. In accordance with the above-mentioned law, we shall therefore say that in a system in which electrical forces alone act there is equilibrium if the electromotive force or the potential is the same throughout. This is the well-known law for conductors of electricity.

With substances which do not allow of any motion of the electricity—that is, with nonconductors—the potential can, it is true, be different in different places. But then, owing to the striving for equalisation on the part of the presential, small displacements are produced in the body, and the reacting forces of elasticity which accumpany these form the compensation

for the inequality of the electric intensity or potential.

When contact between two different substances occurs, a mutual action at the surface of contact is generally set up, and a displacement of energy is thus brought about. The changes in the surface-energy which thus occur seem to be generally compensated by corresponding differences in the electric intensity, i.e. the surfaces of different substances in contact attain different potentials. If the substances are conductors of electricity, each of them must be at a uniform potential at every point within it; hence a difference of potential exists at the surfaces of contact only.

Electrical measurements. In order to examine systematically the nature of electrical phenomena we are at the very beginning obliged to find a measure for them. We generally start from a definition of quantity of electricity, since the historical development of the science has led to the notion that this is one of the most important factors in the phenomena. And yet we have no proof that such things as the hypothetical electric fluids actually exist. What we do know of electrical phenomena are the mechanical, thermal, and chemical effects, i.e. the manifestations of the electrical energy, and it is this which is the real thing underlying the electrical phenomena. Quantity of electricity is a magnitude of the same order as perhaps a volume, and one which can be increased or decreased at will. But electrical energy cannot be destroyed, nor can it be produced; it can only be changed into, or obtained from, other forms of energy.

Electrical energy is then to be measured by the same units as other forms of energy, mechanical energy especially. The unit used for kinetic energy, which is represented by the for-

mula $\frac{m}{2}v^2$ (where m stands for the mass, v for

the velocity), is double that energy which the mass of one gram possesses when moving with the velocity of one centimetre in one second. This being so, the unit accepted for electrical energy is that quantity of energy which is obtained by the transformation of the above-defined quantity of kinetic energy into electrical energy. And further, since, as has been already mentioned, electrical energy has to be looked upon as the product of two factors, the quantity of electricity Q and the potential E, the unit by which the product QE must be measured is thus also fixed.

The units of the two factors Q and E are still arbitrary, in so far as we can choose one of them at will, that for the other being then fixed. In fact, different units have been chosen for different purposes, and accordingly different systems of electrical magnitudes have been obtained. Faraday's law, that equal quantities of electricity travel with equivalent quantities of separate igns, supplies the chemist with a natural unit for quantity of electricity. Hence that quantity of electricity which is combined with one gram of hydrogen as ion will serve as unit of quantity of electricity. Then the unit of potential would have to be the potential at which the above-defined quantity of electricity must be in order to produce unit of work.

This system of units has not become general;

it has been displaced by a system which is derived in a somewhat complicated manner from the action of current electricity on magnets. This system also has not been retained unchanged, but another one has been deduced from it, in which instead of the unit of length of 1 cm. a 10°-fold value has been introduced, while instead of the unit of mass of 1 g. a value 10°-11 times as small is accepted; the second has been retained as the unit of time. Hereby the unit of electrical energy has been changed also; it no longer coincides with the mechanical unit, but is 10° times greater.

In this system the unit of potential is called a volt; in order to get a conception of its magnitude it is to be remembered that the difference of potential at the ends of a Daniell cell is about 1-1 volt.

The unit of quantity of electricity has been called a coulomb. When a coulomb is forced through a volt a quantity of work equal to 10° mechanical units is done.

In order to fix the relations of these units to other units of energy, we must first remember that the work necessary to move 1 g. through 1 cm. against gravity is equal to 980 mechanical units, approximately. The above-defined unit of electrical energy would therefore be equal to 107

 $\frac{10^{\circ}}{980}$, or approximately to 10200 gravitation-units.

Further, the unit of thermal energy is the quantity of heat which raises the temperature of 1 g. of water by 1°C., and which, according to the measurements of Joule, is equal to 42350 gravitation-units, i.e. 42350 g. would on falling through 1 cm. give up 1 calorie of heat, or would heat 1 g. of water by 1° C. Hence this magnitude is equal to 4.15×10^{7} mechanical units. Since the unit of electrical energy amounts to 107 mechanical units, it follows that I calorie is equal to 4.15 electric energy units, or 1 volt × coulomb is equal to 0.241 calories. A number obtained more recently by Dieterici by direct measurements is probably more accurate. According to him, the energy of 1 volt × coulomb is equal to 0.2356 cal.; the unit of quantity of heat here used is 100 of the quantity of heat given out by 1 g. of water in cooling from 100° to 0°. This factor is important for the relations between the heat produced in chemical changes and the corresponding electrical phenomena. Finally, we know from measurements by F. Kohlrausch and Lord Rayleigh that 1 g. of hydrogen as ion carries with it 96540 coulombs. The same quantity of electricity is carried by each equivalent of any other ion, for instance, by 107 g. of silver, $\frac{1}{3} \times 63.4$ g. of copper, $\frac{1}{8} \times 27$ g. of aluminium, &c.

Electric currents. If the potential of electricity is different at different places of a conductor, a movement of the electricity is produced in the same way as motion is produced in a mass capable of moving freely when it is at a higher level than its surroundings. If the difference of potential is maintained, the movement is maintained also.

The compensation of a difference in electric potential necessitates a decrease in the electric energy, which in this process changes into another form. The form most easily produced is thormal energy, but, as has been mentioned

above, it is possible also to obtain mechanical or chemical work.

The measure of the quantity of energy changed into another form is given by the product of the quantity of electricity moved into the decrease of the potential. If the differences of potential are distributed over measurable distances the process is called an electric current The term has been taken from the analogy which in fact does exist between currents of water and currents of electricity. The level of the water corresponds to the potential of the electricity, and the quantity of water corresponds to the quantity of electricity. In both cases the transformable energy, or the available work, is equal to the product of the quantity (of electricity or of water) into the difference of level or of potential, and a current sets in when a difference of level exists. It must only be borne in mind that the phenomena which are brought about by the kinetic energy of the moving masses in water currents have no analogy in the domain of electricity. The electricity behaves as if it possessed only an inappreciably small velocity or mass. Therefore, when the electricity has sustained a definite decrease in potential, it has lost the whole corresponding quantity of energy, while the water can retain a part of it in the form of velocityenergy.

Electric currents are measured by their intensity. By this is understood the quantity of electricity which flows in the unit of time through a cross-section of the current-path; hence the intensity I has to be put as $\frac{Q}{t}$, where t stands for the time. Since electricity moves only when using energy, a loss of electrical energy corresponds to every current, the lost energy generally reappearing as heat. When heat is the only form into which electric energy is transformed, the following equation must hold; W = EQ, and $\frac{W}{t} = EI$, where E stands for the loss of potential between the two ends of the path of the current considered.

Experience has further shown that different conductors when introduced into a circuit cause different losses of potential along their lengths. This property has been ascribed to a resistance of the conductor to the motion of the electricity, in a way similar to that wherein tubes of different bore offer different resistances to the motion of water within them. In accordance with this, the resistance R is defined as the ratio between the difference of potential E and the quantity of electricity forced by means of it, in unit time, through the conductor, or, what is the same, the intensity I. Here we have $R = \frac{E}{I}$ or $I = \frac{E}{R}$. This is the

celebrated law of Ohm, that the intensity or the strength of the current is equal to the ratio between electromotive force and resistance.

Combining this law with the preceding one, it follows that $\frac{W}{t} = 1^{\circ}R$. This expression is the law arrived at experimentally by Joule, according to which, for currents of equal strength, the heat evolved in unit of time is proportional to the resistance, and for equal resistances it is proportional to the square of the current strength.

It is easy to deduce from the units already given the values for the units of the two new terms introduced when defining electric currents. namely, the strength of the current S and the resistance R. The unit of intensity I is that strength of current at which, in every second, one coulomb flows through the cross-section of the conductor; the unit of intensity is called an ampere. The unit of resistance is that resistance by means of which a current of unit intensity (1 ampère) produces in unit of time the unit of heat. As we have seen above, this last is equal to 10' mechanical units, or to 0.2356 calories. An attempt has been made to represent this resistance with the utmost possible accuracy, and it has been found that it equals the resistance of a column of mercury of 1 sq. mm. section and 106.3 cm. in length, at the temperature of melting ice. This unit of resistance has the name ohm. Slightly different to this is the legal ohm, which has been lixed arbitrarily as equal to the resistance of a column of mercury 106 cm. long and 1 sq. mm. section, the exact determination of the true ohm being a very difficult operation. The commercial resistances are graduated according to the legal ohm, and in scientific works in which the absolute value of the ohm comes into consideration, this difference of 3 per thousand must be taken into account. In most cases this is not necessary, just as in most cases it is immaterial whether or not a set of weights is made according to exact grams, as long as it is only made exact in its proportions.

The Law of Faraday. Those substances which allow a movement of electricity through them, i.e. conductors of electricity, are divided into two classes. In the cases considered so far, the assumption has been made that the only form of energy into which the electric energy of the current is transformed is heat. Conductors which undergo no change other than that they get heated when the current passes through them are called conductors of the first class or metallic conductors. To this class belong the metals, their alloys, carbon, and certain compounds.

Now, there are many substances which permit a movement of electricity through them, but in so doing themselves suffer chemical change. To these belong aqueous solutions of acids, bases and salts, as also salts in the molten state, and a few other compounds. Such substances are called conductors of the second class or electrolytes.

The movement of electricity in electrolytes takes place in such a manner that the components of the electrolyte move independently of each other. Hydrogen, the metals, and the metallic radicles move with the positive electricity, or, according to the usual designation, from places of higher to places of lower potential. The halogens, the acid radicles, and hydroxyl, on the other hand, travel with the negative electricity, or from places of lower to places of higher potential.

According to Faraday's nomenclature the components of electrolytes—that is, on the one hand the metals, hydrogen, &c., on the other hand she halogens, the acid radicles, &c.—are called ions. The first named, which travel down with the current are called cations, those which travel up anions.

In a circuit consisting exclusively of an electricity, a motion of electricity can take place without the corresponding chemical action being apparent. But if a conductor of the first class directly touches an electrolyte, whenever there is a movement of electricity there is also a production of the ions at the surface of contact, and the chemical effects become apparent. As proposed by Faraday, the surfaces of metallic conductors, where they touch the electrolytes, are called electrodes. The surface at which the anions appear is called the anode, and that whereat the cations appear is called the cathode.

Faraday also formulated the general law to which all movement of electricity in electrolytes is subject. In every electrolyte the quantity of ion separated out is proportunal to the quantity of electricity which has passed through, and the same quantity of electricity passing through different electrolytes separates quantities of the different ions that are in the ratio of the chemical equivalents of those ions. In these propositions it has been assumed for simplicity's sake that the ions are actually separated out at the electrodes. but this is not essential for the truth of Faraday's law. The following wording completely expresses the actual meaning of Faraday's law: Electricity can move in electrolytes only simultaneously with the ions, and so that chemically equivalent quantities of the different ions carry with them equal quantities of positive or of negative electricity.

We arrive at a perfectly appropriate conception of the nature of electrolytic conduction if we assume that each equivalent of the different ions possesses an equally large capacity for electricity, or, to use the words of Helmholtz, 'the electricity in electrolytes behaves as if it

were divided into equal atoms.'

In applying Faraday's law, it is important that we should keep in mind the difference between the equivalent and the atom; the equivalent weight is equal to the atomic weight divided by the valency. Thus the same quantity of electricity travels with 107 g. of silver, \(\frac{1}{2} \times 0.65 \) G. of zinc, and \(\frac{1}{2} \times 27 \) g. of aluminium; also with 355 g. of chlorine there travels only half as much electricity as with 96 g. of SO. As an amplification of the illustration used above, we must assign to each atom as many equal capacities for electricity as the number of valencies it possesses. Perhaps this is the path by which in the future we may arrive at a elucidation of the nature of chemical valency.

The truth of Faraday's law was tested by its discoverer himself in many ways (Exp. Res. vii. ser.). He convinced himself that the same quantity of dilute sulphuric acid was always decomposed by the same current, whether the electrodes, or the E.M.F., were large or small. Nor did the strength of the acid exert any influence. Finally, he introduced into the same circuit dilute sulphuric acid and tin chloride, lead chloride, or lead borste, or he led the same current through different beakers with dilute sulphuric acid, using electrodes of different metals; in all cases he found his law verified. Later on, other investigators have tested whether part of the electricity is not perhaps conducted through electrolytes in the same way as through metals, but no trace of this has been discovered: in

every case the electricity passed through has compound substance, since otherwise its parts been strictly proportional to the quantity of ion or ions could not transport the electricity in both separated out. And the law of equivalency has also proved itself so correct that it has been used lately as a means for determining equivalent

weights, and hence atomic weights.

The cases in which the same element exhibits different valencies according to circumstances are of special interest. Many such cases have been examined by Regnauld (A. Ch. [4] 11), who formed cells by taking platinum and different metals, along with the corresponding electrolytes. and then determined the quantities of metal dissolved when equal quantities of electricity had been allowed to pass. Thus it was found that mercury in dilute nitric acid has the equivalent 200, since it is changed into HgNO3, a compound of mono-valent mercury; in a solution of potassium cyanide it has the equivalent 100, because it becomes Hg(CN)2, in which the mercury is divalent. Similarly, copper in hydrochloric acid forms CuCl and has the equivalent 63.4; in nitric acid it forms Cu(NO_s)₂, and has the equivalent 31.7. Tin scarcely ever passes into solution except as a di-valent element; it is only in alkaline polysulphides and in a solution of caustic potash containing nitre that it acts as a tetra-valent element. Tellurium also can be made to act as a di-valent and a tetra-valent element. It is known that the elements mentioned show quite different reactions in their solutions, according as they are present as mercurous or mercuric, as stannous or stannic compounds, &c. Hence in these cases the nature of the chemical reactions depends on the quantity of electricity with which the ions are combined.

This is the place to refer back to a misunderstanding concerning the law of Faraday into which Berzelius first fell, and which has recurred many times since. As has been mentioned, Berzelius saw in this law a contradiction to his theory, and tried to refute it by the following argument: if equal quantities of electricity were required for the decomposition of equivalent quantities of the most diverse compounds, it would follow that these could be decomposed by equal forces; this, however, is not possible, since the different substances are evidently held together by quite different forces of affinity. From the illustration given above it can be seen that, contrary to the assumption of Berzelius (which, however, was very excusable, considering the state of electrical science at that time), Faraday's law does not in any way deal with forces, but rather with quantities of electricity. Comparing electrical decomposition to the raising of water out of wells by means of buckets, Faraday's law asserts that in spite of the differences in the depths of the wells, the size of the buckets is always the same. We would fall into an error similar to that of Berzelius if we concluded from the equal size of the buckets that the work necessary for raising the water out of all the wells of different depths was the same. The illustration also shows directly wherein the differences in chemical work, corresponding to the different depths of the wells, assert themselves, namely not in the quantities of electricity required, but in the differences of potential

Electrolytes and ions. It follows from the nature of an electrolyte that it must be a

or ions could not transport the electricity in both directions. Yet all compounds do not possess the power of conducting electricity. In particular, we do not know of any substance liquid at the ordinary temperature which is an electrolyte; amongst pure substances it is only the salts melted at a higher temperature which conduct at all appreciably.

On the other hand, all substances having the character of salts, acids, and bases possess electric conductivity when in aqueous solution. In these cases the water exerts a specific influence, since solutions of the same substances in alcohol conduct much less if at all; and solutions in ether, carbon disulphide, and similar solvents are scarcely conductive.

There are two factors, therefore, which are necessary for the production of electric conductivity, i.e. the nature of the substance and the condition in which it is.

In electrolysis the molecule of the conducting compound appears to be split into two parts. There can be no doubt as to what these parts are with substances such as chloride of silver or potassium iodide: since they consist of two elements only, the metal must be one ion and the halogen the other. The question gets more doubtful with ternary compounds, such as nitrie acid, sodium acetate NaCO₂CH₃, or ammonium chloride NH,Cl. Since, however, no important distinction manifests itself in the behaviour of these substances and those mentioned above, it is simplest and most obvious to assume that their ions correspond to those of the substances first named. Hence the ions of nitric acid are H and NO₃, those of sodium acetate Na and CO₂CH₃, and those of ammonium chloride NH, and Cl.

It is possible to examine this assumption on the basis of Faraday's law. In the electrolysis of potassium sulphate as much oxygen and hydrogen are obtained as from the electrolysis of dilute sulphuric acid by means of the same current, but in addition to this there is found at the anode an equivalent quantity of free sulphuric acid, at the cathode a corresponding quantity of free caustic potash. If we assume with Berzelius that the current has decomposed the potassium sulphate into potassium oxide and sulphur trioxide, K₂O and SO₃, which combine with the water to form 2KOH and H₂SO₄, we should have to assume further that the same current had in the same electrolyte simultaneously decomposed an equivalent quantity of water. But this is in contradiction to the law of Faraday. If we assume, however, that the ions are K2 and SO4, it is comprehensible that the potassium separated out should act on the water of solution, evolving hydrogen, according to the equation $2K + 2H_2O$ = 2KOH + H.; in like manner the ion SO, acts on the water and forms sulphuric acid and free oxygen, according to the equation H2O + SO4 = H.SO. + O. With those metals which do not decompose water, such as zinc, copper, and silver, we actually obtain the metal only at the cathode; and similarly, solutions of chlorides, bromides, and iodides do not generally give free oxygen, but free halogen.

It is necessary, therefore, to distinguish carefully between the primary and the recondary effects of electrolysis. The primary effects consist In the separation of the ions at the electrodes. But since the ions do not continue to exist as such after having given up their electricity, they undergo further changes according to circumstances. The simplest case is that of the metallicions, when these cannot act on the water; they simply become solid or liquid metals. So also the separated atoms of the halogens pass on, combining into gaseous chlorine, Cl., or into the molecules of the dissolved bromine or iodine.

The metals which decompose water can still be obtained in the metallic state when water is excluded or reduced to as small a quantity as is possible. A classical example of this is furnished by the electrolysis of slightly moistened potash, by means of which H. Davy discovered potassium. The electrolysis of molten salts, that of the chlorides especially, furnishes a means for preventing the secondary reaction of the metals; such electrolyses, which had first been used by Bunsen for scientific investigations, have obtained at the present time great technical importance in the production of magnesium and aluminium.

Complex cations of the type of ammonium, NH_a are very unstable, and until recently it was doubfful whether the so-called ammonium amalgam, which is obtained on using a mercury cathode in the electrolysis of ammonium chloride, really contained the compound radicle NH_a. By measurements of another kind (viz. of the electromotive force) the existence of ammonium in the amalgam has now been placed beyond a doubt.

The compound anions as such are all of them very unstable. Many of them, such as the anions . of the nitrates, phosphates, sulphates, &c., simply act on the water by taking up from it the hydrogen required to produce acids, and liberate the oxygen. The latter, which appears in the nascent state, is capable of bringing about powerful oxidising effects. If, for instance, lead or manganeso salts are electrolysed, the oxygen acts on the dissolved metal and separates it at the anode as peroxide. In other cases the anion splits up into more stable compounds. Thus in the electroly is of formates we obtain carbon dioxide and hydrogen from the ion HCOO, according to the equation $2H600 = H_y + 2CO_{\infty}$ The acctates give carbon dioxide and ethane $2CH_1CO_2 = C_2H_0 + 2CO_2$, and similarly the salts of the higher fatty acids give the corresponding paraffins.

In some cases the secondary action can take place in another direction; in this manner the formates can produce—instead of hydrogen and carbonic acid—water, carbon dioxide, and carbon monoxide, as is shown in the following equation, $2H \cap O_1 = H_1O + CO + CO_2$. In most cases such secondary processes take place along with the primary actions, and the proportion between the two depends on external circumstances, temperature, concentration, current-density, &c.

In a few cases it is somewhat difficult to recognise the primary or secondary character of a product of electrolysis. On electrolysing potassium silver cyanide or sodium platinichloride, silver or platinum separates at the cathode, so that it seems as if the silver oyanide or the platinichloride were decomposed primarily. This, however, would be an erroneous view, since the

ions of the salts are K and Ag(CN),, and Ma, and PtCl, respectively, and the heavy metals are only scondarily reduced from the sclutions by the alkali metals. We can convince ourselves of this by using small electrodes and strong ourrents, when the salt near the cathode is soon used up, and potassium (or sodium), or, more correctly, hydrogen which has been formed secondarily, separates. More distinct proof of the nature of the ions is, however, obtained by studying the migration of the ions, to be discussed later.

So far the assumption has been made that the ions exert no action on the metal of the electrode; this, however, is not always correct. Only a few metals when used as anodes offer resistance to the chemical attack of the anions. If the metal can combine with the anion it forms the corresponding sait, which either dissolves in the water of solution, or, if insoluble, remains attached to the electrode and often interrupts the current. But also when used as cathoden the metals often combine with the cation; thus mercury forms amalgams, and the hydrogen separated at the cathode is occluded in greater or smaller quantities, especially by palladium and platinum, and also by iron. In other cases the cathode simply becomes coated with a layer of the corresponding metal, which separates more or less uniformly according to its nature and that of the electrolyte. These processes are used for coating substances which are conductors, or if non-conductors, whose surfaces at least have been made conductive; such processes have also been employed for galvanoplastic coating with gold, silver, copper, &c.

The constitution of electrolytes. It has already been remarked that all compounds are not electrolytes, and that some substances which do not conduct electrolytically by themselves obtain this power when dissolved in certain solventa, especially in water. From this it follows that electrolytes have a special constitution with which their special property is connected. question as to what this constitution is has scarcely been raised yet, much less has it been answered. This is because most of the com pounds known in the days of the electrochemics system of Berzelius were electrolytes, and late on, when many organic compounds, which ar mostly non-electrolytes, were discovered, th electrochemical theory had been given up, an the interest in it had disappeared. The fire investigator who proposed the question clearly and who, as far as he could, answered it-wa Hittorf. He it was who established the proposi tion 'electrolytes are salts.' Under the nam of 'salt' Hittorf comprised all those compound which are capable of exchanging their consti tuents within the shortest time. Hence alon with the salts proper must be classed acids an bases.

By enunciating this law, Hittorf was the first to draw attention to a most important relation which has become the starting-point for the due-comprehension of the constitution of electrolytes. The power to conduct electricity and the power to exert chemical reactions are so closely parallel that both must be considered as the outcome of the same cause. This cause, however, has to be looked for in the constitution of the electrolytes themselves.

Electrolytic conduction is brought about by the positive and negative electricities moving through the conductor bound to their ponderable carriers, the ions; it is necessary, therefore, to assume a considerable mobility of the ions.

And, further, electrolytic conduction occurs in consequence of any difference in potential, however small. It is necessary, therefore, as was already pointed out by Clausius (P. 101, 338), that in every electrolyte there should be present a certain number of ions capable of moving freely, i.e. in every electrolyte a portion of the salt-like compound which produces the conduction must be partly split up into ions. Clausius left undecided how great this portion is, as he possessed no means to determine it. To the chemists who, in consequence of a peculiar shifting of judgment, considered electrolytes generally as specially stable compounds, he made the concession that this portion might be very small. In the imagery of the kinetic hypothesis he conceived that, owing to the collision of the molecules of the electrolyte with each other and with those of the solvent, one or other occasionally splits into its constituents, and so gives the necessary free ions.

It is now possible to urge similar considerations from the chemical side. While gaseous substances at the ordinary temperature react but seldom, acids, bases, and salts dissolved in water do so instantaneously. A mixture of oxygen and hydrogen does not form water until it has been heated to between 400° and 500°; a mixture of hydrochloric acid and potash, however, when in aqueous solution, passes so quickly into potassium chloride that it has been found impossible as yet to determine the time required for the change, and yet in the first case 68,000 cal. of heat are produced, while in the second the heat produced, or the energy liberated, is only 13.700 cal.—that is, five times less. In general, non-electrolytic solutions also react with each other extremely slowly. An example of this is afforded by the means which must be taken to hasten the reactions of non-electrolytes, and especially of organic compounds; this has to be done by heating the reacting mixtures, often under increased pressure. For the formation of scetic ether from a mixture of alcohol and acetic acid-that is, for a process intimately connected with that of the formation of salts-at least ten years are needed, at the temperature of the room, before it has approximately attained the end which under these conditions it can reach. From the chemical point of view, therefore, it is necessary to suppose that compounds which react instantaneously—that is, electrolytes—possess a special mobility of their parts or ions; and that it is the constituents of 'salts'-the term being used in the widest sense -which are the ultimate causes of electrolyses as well as of chemical reactions. These constituents of salts are, on the one hand, the metals, the metallic radicles, and hydrogen; on the other hand, the halogens, the acid radicles, and hydroxyl. It is possible, therefore, to apply to substances which react rapidly -that is, to salts, as this term was used by Hittorf- the same kinetic considerations as were made use of by Clausius to show the presence of ions in electrolytes.

We are now confronted on both sides by the

question of how great is the proportion of free ions, or of decomposed molecules, in solution of electrolytes. The fact that a maximum reacting power exists for a given class of substances is in contradiction to the assumption that this proportion is inappreciably small. It has already been explained (compare the article Appinity) how the substances which have been most carefully examined from this point of view—the acids—exert their chemical reactions according to a definite co-efficient which is characteristic of each acid. This co-efficient-which can be determined, for instance, by merns of the velocity of inversion of cane sugar-cannot be increased at will. and does not exceed a definite maximum value, which maximum is possessed by hydrochloric acid, nitrie acid, benzenesulphonic acid, &c. All the conditions-such, for instance, as the introduction of oxygen, sulphur, or halogen into the molecule --which increase the velocity of reaction of weak acids are without any measurable effect on the strongest acids. From this it follows that the circumstance which is the cause of the velocity of reaction - that is, the unimpeded mobility of the ions—has in these substances alrealy reached its highest degree, or is at least very near to it, since, in opposition to Clausius and to the views current till now, we must assume that in aqueous solutions of these strong acids it is not, perhaps, a few hundredths or thousandths of the molecules present which are split into their ions, but rather that by far the greater part of the electrolyte is split into ions.

A similar conclusion can be drawn from the degree in which electrolytes conduct the current. The more detailed consideration of this subject will be taken up presently. Here it will only be mentioned that the results of these investigations agree completely with those on the velocities of reactions.

A third entirely independent verification of the unexpected conclusion that aqueous solutions of the strong acids are nearly completely dissociated can be gained from a study of the properties of these solutions.

Only so much of van't Hoff's theory of solutions (Z. P. C. 1, 481) as is necessary for understanding the constitution of electrolytes will be explained here,

The fundamental idea of van't Hoff's theory is as follows. The physical properties of gases, and especially the relations between pressure, volume, and temperature, are practically independent of the special nature of the substance, while such an independence does not exist with liquid and solid substances. The cause of this phenomenon may be sought in the fact that the smallest parts or molecules of gases are always at such a distance apart that they are not capable of exerting an action on each other. In liquid and solid substances, however, the molecules are in close proximity, and exert, therefore, their specific reciprocal actions. But there is another condition in which the molecules of a substance are relatively distant from each other, namely, when the substance is present in a solvent in the state of a dilute solution.

We should expect, therefore, that in this state matter would be subject to laws analogous to those which hold for gases.

The first property characteristic of gases is

their power of extending uniformly through any given space. Solutions exhibit the same pecu-When the pure solvent is placed over the solution of any substance, the substance begins directly to enter into the solvent (the pure solvent playing the part of a vacuum), and the movement does not cease until, as with gases, the substance is uniformly distributed through the whole space. The only apparent difference is that in the case of gases this process is completed in a very short time, while with solutions months, and even years, are needed in order to bring it, practically speaking, to an end. This movement can be impeded by introducing between the solution and the pure solvent a partition which allows the passage of the latter but not of the former. Such a 'semi-permeable' partition can be produced by saturating a porous clay cell, for instance, with a solution of copper sulphate. washing the cell, and filling it with a solution of potassium ferrocyanide. A pp. of amorphous copper ferrocyanide is thus formed in the pores of the clay, and this pp. allows the passage of water through it, but does not allow various other substances to pass. In order to arrive at a conception of the cause of such a property we can imagine that the pp. of copper ferrocyanide acts as a filter which allows the passage of the smaller water molecules, while it retains the larger molecules of the dissolved substance.

W. Pfeffer, who has studied such cells very thoroughly, found that if the cells are closed a very considerable amount of pressure is produced in their interior. A 1 p.c. solution of sugar produces a pressure of more than 50 cm. of mercury; a solution of nitre of equal strength gives pressures of between three and four atmospheres. Pleffer also found that the pressures increased, at constant temperature, to maximum values, which remained constant as long as the partition remained intact. These pressures proved to be proportional to the concentrations, and further, they increased with a rise of temperature.

According to van't Hoff, this pressure, the 'osmotic pressure,' is to be looked on as analogous to the gaseous pressure. It is possible to form a similar conception of its cause as is formed of the cause of gaseous pressure; the molecules of liquids, like the molecules of gases, possess a quantity of kinetic energy which is proportional to the temperature. The solvent—for instance, the water—can pass through the semipermeable wall, and since it is present on both sides its pressure is the same on both. The substance dissolved, however, bombards the wall from one side only, and thus a pressure is set up. This view-which, however, is only hypothetical, and which can be accepted or rejected without the 'heory itself being called in question -has been objected to on the ground that if it were true a weak-walled vessel must needs be broken by a solution placed in it. But this assertion overlooks the important point that the osmotic pressure can exert itself only within the solution. If we imagine for simplicity's sake a drop of a solution floating in space, it is true that a pressure due to the substance dissolved will be exerted on the internal surface of the drop, which pressure may easily amount to 100 atmospheres. But to this pressure there is opposed the normal capillary pressure of the liquid, the magnitude of

which we do not yet know very exactly, but of which we can assert that it has to be measured by thousands of atmospheres (in the case of water it is approximately 20,000 atmospheres). Hence this pressure is under all circumstances quite sufficient to maintain equilibrium with the osmotic pressure, and the only effect of the latter is to slightly increase the volume of the solution.

It has been shown by van't Hoff that the laws of osmotic prossure exactly coincide with those of gases. Boyle's law enunciates that pressure and volume are inversely proportional. Pfeffer's law says that pressure and concentration (or density) are proportional; this agrees with Boyle's law. Further, the law of Gay-Lussac tells us that at constant volume (or at constant density) the pressure of a gas increases with the temperature, and that for each degree it does so by $\frac{1}{2}$ of the value at 0°. A similar thing has been proved by van't Hoff from the numbers obtained by Pfeffer. And finally for gases we have the law of Avogadro, that, temperature and volume being the same, equimolecular quantities of different gases exert the same pressure. Taking the molecular weights in grams, and taking for the common volume 1 litre, then at 0° this pressure is equal to 22.37 atmospheres. Now, it has been observed by Pfeffer that the osmotic pressure of a one per cent. solution of cane sugar, which therefore con-tains 10 g. in one litre, is 0.649 atmospheres at 0°. The molecular weight of sugar C, H, O,, is 342; a solution containing this quantity in grams in one litre would exert a pressure W times as great - that is, a pressure of 22.2 atmospheres. This number agrees within the limits of experimental error with that which holds good for gases; and hence Avogadro's law holds also for solutions, or, more correctly, so far, for solutions of cane sugar.

The question whether the law holds for other dissolved substances must be answered in the affirmative. It is true that only very few measurements of osmotic pressures have been made, but these phenomena are so closely connected with others to be considered shortly, that it has been possible to place the general validity of the law beyond doubt.

Let us imagine a solution poured into a vessel of the form of an inverted funnel, the opening of which is closed by a semi-permeable wall in contact with which is a quantity of the pure solvent. Then the solution will rise in the tube, because of the greater internal pressure, and equilibrium will be established only when the pressure of the liquid column in the tube has become equal to the osmotic pressure. Let this arrangement be covered by a bell-jar. from which the air has been completely expelled; the solution will then be surrounded by the vapour of the solvent only. But the pressure of the vapour is slightly smaller in the upper part of the bell-jar, at the level of the solution, than below at the level of the pure solvent, and it is smaller by an amount which is equal to the pressure of the weight of the vapour present between the two levels. Moreover, it is by this amount that the vapour-pressure of the solution must fall short of that of the solvent, because, if this were not the case, liquid would either continually evaporate, or condense, at the surface of the solution; in consequence of the osmotic pressure, the changes in level produced would always equalise themselves again, and we should have a perpetuum mobile, which is impossible.

It follows, therefore, that in general the vapour-pressure of a liquid must decrease when a substance is dissolved in it, and that this takes place according to laws which run parallel with those of osmotic pressure.

This theoretical conclusion is in accordance with observation. It has been found by Wüllner (P. 103, 529) that, at a constant temperature, the decrease of the vapour-pressure of an aqueous solution is proportional to the concentration of the solution. Babo on his part had established that the ratio between the vapourpressures of the pure solvent and the solution is independent of the temperature. Both results have been confirmed, on the whole, by later investigations. Raoult especially has occupied himself with this question; he has shown that this behaviour is general, and he has also found that equimolecular weights of different substances dissolved in the same solvent produce equal diminutions of the vapour-pressure, and finally that on using equimolecular quantities of different solvents the relative diminution in the vapour-pressures is the same. If f stands for the vapour-pressure of the solvent, f' for that of the solution, and if further N stands for the number of molecules of the solvent (in gram-units), n for the number of molecules of the substance dissolved, the general expression holds

$$\frac{f-f'}{f} = \frac{n}{N+n}.$$

 $\frac{f-f}{f} = \frac{n}{N+n}.$ While Raoult discovered this law empirically, van't Hoff has deduced it theoretically from the laws of osmotic pressure (Z. P. C. 1, 494).

This formula can be used for determining the molecular weight of a substance in solution. Let p grams of a substance with unknown molecular weight m be contained in 100 g, of the solvent, the molecular weight of which is M; then $\frac{p}{100}$ M = grams of substance dissolved in one molecular weight of the solvent; let this = s; then putting $n = \frac{s}{m}$, and N = 1, and solving the

equation for
$$m$$
, it follows that $m = \frac{sf'}{f - f''}$.

Finally, a third set of phenomena is known, governed by similar laws. It has long been known that salt water freezes at a lower temperature than pure water. As far back as 1788 Blagden (T. 1788) established the fact that the lowering of the freezing-point of a solution of salt in water is proportional to the amount of salt dissolved. Later on, Rudorff (Pal14, 63) rediscovered this fact, which had been forgotten, and de Coppet found that equimolecular solutions of salts having analogous constitutions exhibited equal lowerings of the freezing-points (A. Oh. [4] 23, 366). Raoult discovered that the same law held for the most diverse solvents. This law states that equimolecular quantities of whatever substances we take, added to a constant quantity of the solvent, lower the freezing-point by the same amount (C. R. 1882). Raoult thought for a time that the lowering of freezing-point was the same for equimolecular quantities of different

solvents, but this proved to be erroneous. Van't Hoff has deduced this important relation from the laws of osmotic pressure, and his formula agrees well with experiment (Z. P. C. 1, 481).

We can convince ourselves of the necessity of these relations by an argument similar to that used in order to prove the connection between osmotic pressure and change of vapourpressure. As the mechanical theory of heat tells us, below 0° the vapour-pressure of ice decreases more rapidly than that of over-cooled water. A temperature must therefore exist whereat a saltsolution, which has a vapour-pressure less than that of water, exhibits the same vapour-pressure as ice. This is the only temperature at which the solution can exist side by side with ice, as otherwise a perpetuum mobile would be possible. Since, therefore, this temperature, which is the freezing-point of the solution, is in inseparable connection with its vapour-pressure, the laws holding for the one must also hold for the other, and from this the laws already stated follow directly. Formulating these laws, we get $\Delta = r \frac{p}{ml}$

where Δ is the lowering of the freezing-point, lthe weight of the solvent, p that of the substance dissolved, and m the molecular weight of the substance, while r is a constant dependent on the nature of the liquid. From the formula it

follows: $m = \frac{rp}{\Delta t}$. Having, therefore, once for

all determined the constant for a solvent, it is possible to find the molecular weight of a substance by determining the lowering of the freezing-point of its solution in that solvent. Van't Hoff has shown that the constant can be deduced thermo-dynamically from the heat of fusion of the substance.

If we now apply these methods for determining the molecular weights of dissolved substances to solutions of electrolytes, we find that the molecular weights appear smaller, and hence the number of molecules in solution are greater, than correspond with the formule. In many cases the amount of this deviation is very considerable, and its existence at first proved a great obstacle in the way of van't Hoff's theory of solutions. To Arrhenius (Z: P. C. 1) we owe the means of accounting for the deviation. The views propounded by this investigator have shed such a flood of light over difficult questions in chemistry and physics that we must consider the work of Arrhenius to be one of the most important advances ever made in this and in allied domains.

Arrhenius' idea consists in ascribing the deviations of the observed from the calculated molecular weights, to a dissociation of the electrolytes into their ions. From the magnitude of this deviation a conclusion can be drawn as to the number of molecules which are dissociated; the problem which was left unsolved by Clausius thus receives its solution.

Reserving the numerical proofs of the truth of this view till later on, it is proposed to deal first with some possible objections and diffi-culties of a general nature.

The application of the hypothesis leads to the conclusion that in moderately dilute solutions of strong acids and bases, and also of normal salts, as much as 80 to 90 per cent. of the substance in solution is dissociated into its ions. Hence a solution of potassium chloride contains little else than ions of chlorine and potassium. How is it that the chlorine does not escape into the air as a greenish yellow gas, and the potassium does not act on the water?

The answer lies in the consideration that the chlorine which we know as a greenish yellow gas is the electrically neutral molecule Cl₂, and does not consist of the separate atoms of Cl which are charged with a large amount of negative electricity. The potassium again is not present as the compact metal, but in the form of strongly positively charged ions. Considering the great differences exhibited by allotropic forms of the same element (oxygen and ozone, red and yellow phosphorus, &c.), we cannot wonder that in these cases also considerable differences appear.

And it is further possible to produce solutions in which such ions -as, for instance, potassium-are present in excess, and therefore certainly in the free state. For this purpose, let us imagine two vessels filled with notassium chloride solution and placed on an insulating stand, and then connected conductively by means of a syphon filled with the solution. Let us now bring near to the one vessel a body charged with negative electricity. The vessel becomes charged positively by induction, and an equivalent quantity of negative electricity moves through the syphon into the second vessel. If we now remove the syphon, and then the body charged, the first vessel remains charged positively, the second vessel negatively. So far the experiment contains nothing that is new; it is the elementary . experiment used for proving the inductive effect of electricity. If, however, we pay attention to the fact that, according to the law of Faraday, electricity can move in electrolytes only simultaneously with the ions, the conclusion is inevitable that an excess of potassium ions must be present in the vessel charged positively, and the same excess of chlorine ions must be present in the vessel charged negatively. These excesses of ions are maintained as long as the electric charge of the vessels exists. On discharging the vessels the ions give up their electricity, and the substances appear at the point of discharge endowed with their usual properties.

Owing to the magnitude of the quantities of electricity contained in the ions, the question may be raised whether the experiment which has just been indicated really can be carried out. Ostwald and Nernst have shown (Z. P. C. 3) that this is actually possible. By means of a mercury electrode contained in a capillary tube, such small quantities of hydrogen can be observed that the experiment becomes quite feasible. Since under ordinary conditions one gram of hydrogen occupies a space of about 12,000 c.c., a small bubble of 0·1 mm. diameter, which one can still see with the naked eye, has a weight of only 10⁻¹⁰ g., and one of 0·0·1 mm. diameter, which can be seen

one of 0'01 mm. diameter, which can be seen

1 From the number, already given, of 96,540 coulombs,
which are combined with 1 g, of hydrogen and which are
also present in one litre of normal potassium chloride solution—as positive electricity on the potassium, or negative
electricity on the chlorine—it is possible to calculate that
this quantity of electricity would suffice to charge a sphere
of an approximate diameter of 10's cm.—which, therefore,
would be larger than the whole solar system—to a potential
effort one volk.

under a microscope, has a weight of only 10⁻¹³g. This is as small a quantity of matter as can be recognised in any way, and the electricity combined with it can be detected in an apparatus of very moderate dimensions.

Thus the experiment described above is not only conceivable, but feasible; and thus it is proved that free ions, such as those of potassium, can be present in aqueous solutions without acting on the water.

The assumption that some of the molecules of electrolytes are split into ions in solutions explains many properties of these solutions. In the following paragraph we will assume for simplicity's sake that the splitting up is complete—an assumption which is nearly correct in the cases of salts, strong acids, and bases; the modifications which must be introduced into these considerations by taking into account the portions not split up, will be considered afterwards.

Let us consider, first, the chemical reactions of electrolytes. As is well known, certain reactions are used in analytical chemistry for indicating definite substances. These reactions indicating definite substances. must take place quickly, as otherwise they would be of no practical use; hence they must be reactions between ions. If asked what it is that the ordinary analytical reactions allow us to recognise, we are inclined to answer, the different chemical elements. But this is not at all appropriate. A solution of a salt of silver is called a reagent for chlorine, and in fact by its help chlorine can be detected in metallic chlorides. But the chlorine in potassium chlorate or in monochloracetic acid cannot be detected by means of silver solution. In the same way chlorides indicate silver; but the silver in potassium silver evanide cannot be recognised by means of chlorides. The different oxyacids of sulphur also give quite different reactions, though they all contain the same elements; similarly, the reactions of iron, copper, mercury, tin, &c., are quite different, according to the degree of oxidation of the metal.

These examples prove that it is not the elements which are indicated by analytical reactions. A more careful consideration shows that since it is the ions which react, the ions are indicated by the analytical tests.

This simple proposition removes all the difficulties which confronted us. If a solution of silver is a reagent for chlorine ions, naturally it cannot indicate the chlorine in potassium chlorate, whose ions are K and ClOs; nor in monochloracetic acid, whose ions are H and CH2ClCO2. And, conversely, silver is indicated by chlorides only where it appears as the ion; but the ions of potassium silver cyanide are K and Ag(CN). The behaviour of chloroplatinic acid H.PtCl₆ towards silver solutions is specially remarkable, a behaviour about which an incredible confusion has reigned in chemistry, because it has always been believed that its chlorine must be precipitated by silver solution as silver chloride. matter was first cleared up by Jörgensen (J. pr. [2] 16), who found that no silver chloride is formed at all, but rather the silver salt of chloroplatinic acid Ag,PtCle; sodium platinichloride is completely precipitated by two equivalents of silver solution only, instead of by six, which correspond to the proportion of chlorine.

Thus the so-called anomalies of analytical reactions are fully explained. It is further explained why, for instance, all the different sulphates give the same reaction with barium chloride. The nature of the metal is of no account, because the reacting ion SO, is not combined with the metal at all, but exists by itself. It is a remarkable fact that similarly con-

stituted ions give, under certain conditions, different reactions. According to this view, the iron in a solution of FeCl_n, and also in a solution of FeCl_n, is contained as an ion; yet the two act differently. In like manner, solutions of K₁Fe(CN)_a, as well as those of K₂Fe(CN)_a, contain the same negative ion Fe(CN)_a, and those two substances give quite different reactions. The explanation lies in recognising that these similarly composed ions are endowed with different quantities of electricity according to their valency. Thus iron appears divalent and trivalent, mercury and copper monovalent and divalent, the atomic group Fe(CN)_a tetravalent and trivalent, in that they contain corresponding numbers of positive or negative electric units or 'atoms.'

If the theory developed so far is correct, then all properties of salt solutions must be of an additive nature with regard to the two ions—i.e. their properties must be made up of two parts, one of which depends only on the positive ion, and the other only on the negative ion. This fact was recognised before it found an explanation in terms of the hypothesis of the independent existence of ions in solutions. Arrhenius drow attention to this fact (Z. P. C. 1) when he was establishing his theory. Some examples will make the point clearer.

In 1874 Valson enunciated a law concerning the specific gravities of salt solutions (C. R. 73), which he called the law of the moduli. By means of it the specific gravity of a 'normal' solution-that is, of a solution containing one equivalent of the salt in grams in one litre-of any salt can be found by adding to the specific gravity of a solution of ammonium chloride (chosen as the standard) two values, one of which depends on the metal only, and the other on the acid radicle only. According to Valson, these moduliare (NH, ClAq of specific gravity 1015 being taken as the standard); -K = 30, Na = 25, $\frac{1}{2}Ca = 26$, $\frac{1}{2}$ Mg = 20, $\frac{1}{3}$ Sr = 55, $\frac{1}{3}$ Ba = 73, $\frac{1}{3}$ Mn = 37, $\frac{1}{3}$ Fe = 37, $\frac{1}{3}$ Zn = 41, $\frac{1}{3}$ Cu = 42, $\frac{1}{3}$ Cr = 61, $\frac{1}{3}$ Pb = 103, Ag = 105; Br = 84, I = 64, $\frac{1}{3}$ SO₄ = 20, NO₄ = 15, $\frac{1}{3}$ CO₂ = 14, HOO₄ = 16. To these are added the value zero for NH, and Cl. These values allow us to calculate the specific gravities of solutions of 14 × 7 = 98 salts, and the calculations agree very well with experiment. Later on (1883), the law was confirmed by C. Bender (W. 20, 560), and by Nicol (P. M. [5] 18, 179), and was also extended by the first named.

A similar law was established by Gladstone (Pr. 16, 439) for the refraction-equivalents of salts. Gladstone expressed his generalisation in the form that the difference between the refraction-equivalents of the salts of two metals with the same acid is always the same, and is independent of the composition of the acid. The following table shows how the values agree in the cases of salts of potassium and sodium with soids of different compositions:—

	Potassium	Sodium	Difference
Chloride	18-44	15.11	8.8
Bromide	25.34	21.70	8.6
Iodide	35.33	31.59	8.7
Nitrate	21.80	18.66	8.1
Hydrate	12.82	9.21	. 3.6
Alcoholate	27.68	24.28	8.4
Formate .	19.93	16.03	8.9
Acetate	27.65	24.03	3.6
Tartrate	57.60	50.39	8.6
Carbonate	34.93	28.55	2 × 3·2
Bichromate .	79.9	72.9	2 × 3·5
Hypophosphite .	26.94	20.93	2 × 3·0

A similar law exists for the salts of strong acids, but with the weak acids the differences are much greater. We are now in a position to account for this discrepancy, which was left unexplained by Gladstone. Since the weak acids are only very partially split into their ions, it cannot be expected that hydrogen as an ion should have the same refraction-equivalent as it has in the undecomposed compound.

Gladstone also enunciated the general law that the colour of the solutions of salts whose acid or whose metal form coloured compounds is independent of that of the other constituent (P. M. [4] 14, 418). If we consider how dependent colour is on constitution in other cases, this fact must be considered as a specially weighty proof of the mutual independence of the ions.

The knowledge of the fact that the characteristic colours of salts are dependent on the nature of the coloured ion only, and are independent of that of the other ion, has existed for a very long time, almost, as one might say, unconsciously. In green liquids we should always expect nickel, in red ones cobalt, in pale blue ones copper, &c. Some exceptions to this can easily be explained. One such exception is that most copper salts show the blue colour of the copper ions, while concentrated solutions of copper chloride appear green. The cause of this is that in concentrated solutions a considerable number of undecomposed molecules CuCl, are present, which molecules are coloured a deep yellow, as can be seen in dry copper chloride, which looks almost reddish brown. This yellow colour mixes with the blue colour of the copper ions, and produces the green colouration. From the fact that as the temperature is raised the green colour becomes more intense, it must be concluded that with rise of temperature more molecules CuCl, form at the cost of the ions (v. Ostwald, Z. P. C. 9, 579).

Another additive property has been found by Marignac (d. Ch. [5] 8, 410) in the specific heats of salt solutions. This property is, however, partly hidden by small deviations which, though capable of explanation, require the knowledge of some quantities the measurement of which has not yet been undertaken.

And, further, Ostwald (J. pr. [2] 18, 853) has proved such relations to hold in a fairly extensive manner for the volume-changes accompanying neutralisation. On saturating solutions of potash, soda, and ammonia by the same acid the total volume changes in a very different manner. These volume-changes are, however, governed by the law that on saturating two bases by the

same acid the difference of the volume-changes is independent of the nature of the acid; and in like manner the difference in the volume-change on saturating two different acids by the same base is uninfluenced by the nature of the base. Hence the volume-change always depends on two constants, one of which is determined by the acid only, and the other by the base only; the specific nature of the salt formed has no influence. The following table shows these relations:—

	Potassium	Sodium	Ammonia
Nitrie acid	20.0	19.8	- 6.4
Hydrochloric acid .	19.5	19.2	- 6.6
Hydrobromic acid .	19.6	19.3	- 6.6
Hydriodic acid .	19.8	19.6	- 6.4
Formic acid	12.4	12.1	-13.6
Acetic acid	9.5	9.3	-16.3
Monochloracetic acid	10.9	10.6	-15:1
Dichloracetic acid .	13.0	12.7	- 13.0
Trichloracetic acid.	17.4	17.1	- 8.7
Isopropionic acid .	7.8	7.7	-17.8
Butyric acid	7.0	6.8	-18.6
Isobutyric acid .	6.3	6.1	-19.3
(Hycollic acid	9.6	9.8	- 16.5
Lactic acid	8.3	8.1	-17.7
Sulphuric acid .	11.9	11.5	-14.4
Oxalic acid	9.9	9.7	-16.1
Succinic acid.	8.2	7.9	-17.6
Malic acid	8.6	8.5	-17.4
Tartaric acid	9.4	9.2	-17.0

The differences between the corresponding members of two horizontal or of two vertical columns in this table are seen to be constant within the limits of error. The all but complete equality of the values for the four first-named acids, which are almost completely split up into their ions, is remarkable.

The most striking case of the additive properties of salt solutions is, however, given by their thermal relations. Hess long ago established the law of the thermo-neutrality of salts: this law declares that there is no thermal effect on mixing the solutions of two salts provided that everything remains in solution. This fact is difficult to understand as long as eve assume the existence in an undecomposed state of normal salts in solutions, since the mutual changes of the salts would have to proceed without any energy-change, and this is a behaviour without analogy. If we assume, however, that the solutions of the salts contain chiefly the ions of the salts, the fact becomes explicable, because on mixing the solutions, the ions remain unchanged, they do not influence each other, and hence there is nothing to cause thermal effects.

More remarkable still is the explanation which the theory gives concerning the heats of neutralisation of acids and bases. At first sight it seems as if no action could take place between a ch compounds, if we consider the strong acids and bases to be almost wholly separated into ions. Because if the solution of the acid, of the base, and of the salt contains ions only, no change ought to occur when the acid and the base are mixed. If, however, we consider the reaction more carefully, we arrive at different results. For instance, let there be given soda

and hydrochloric acid; the reaction will be

Na + OH + H + Cl = Na + Cl + H.O

The ions sodium and chlorine remain unchanged; but since water conducts very badly, only a very slight separation of H.O into the ions OH and H can occur, hence when the ions OH and H meet they must combine to form H₂O.

Hence the process of neutralisation in aqueous solutions is not a combination of the constituents of the salt, but only a combination of the constituents of water.

It is true that this remarkable result is somewhat contradictory of the usual views on the subject, but it is in complete agreement with the facts. If the process of neutralisation between acids and bases decomposed into their ions really consists only in a formation of water from hydrogen and hydroxyl, then its concomitant phenomena must be independent of the nature of the acids and the bases.

The most impertant of these concomitant phenomena is the heat of neutralisation. This value has been determined by different observers, with special exactness by Thomsen (Th. 1). A number of measurements are collected in the following table, calculated for one equivalent; the unit used is the rational calorie, K=100 gram-units of heat:—

кон LIOH BaO H. CaO H. NaOH HCI. 137 137 187 139 139 HBr 137 137 HI. 137 136 HNO. 137 138 140 139 HClo, 138 138 140 HBrO. 138 138 HIO, 138 138 141 143 λΗ₂S₂Ò, 135 139 iΗ,PiCl.. 136

And, similarly, tetramethylammonium hydroxide, platinodiamine hydroxide, and triethylsulphine hydroxide give with hydrochloric acid 138, 137, and 137 K respectively.

From this table, which could easily be enlarged, it follows that the heat of neutralisation of the strong acids and bases is a constant, and is approximately equal to 13,700 cal. This number must be looked on as very nearly equal to the heat of formation of water from the ions

H and OH. (A more exact calculation gives 13,500 cal.) The small deviations which are still present originate in the fact that the splitting up of the acids and bases referred to, though very considerable, is yet not quite complete; it is in this undecomposed remnant that the individual nature of the two substances still asserts itself a little.

The conditions become quite changed when we consider the weak acids and bases. Here the constancy of the heat of neutralisation ceases completely, and values are observed which fluctuate between 163K and 10K. In these cases the quantities of heat which are concerned in the splitting up of the acid and the base into their ions must be taken into account, besides the heat of formation of water from its ions, and the heat

of neutralisation may be represented by an expression of the form N = 13,500 + A + B, where A + B is the quantity of heat necessary for decomposing the acid and the base into ions. As experiment has shown that the salts when in dilute solution are uniformly and nearly completely decomposed, their heats of decomposition need not be taken into account meanwhile. This formula also expresses a law which, discovered some time back by Favre and Silbermann (A. Ch. [3] 37, 486), has been confirmed by the younger school of thermo-chemists. This law is, that the difference between the heats of neutralitation of any two bases is always the same whatever acid is taken, and that likewise the difference between the heats of neutralisation of any two acids is independent of the base. This is only another expression for the proposition that the acid and the base each contributes towards the heat of neutralisation a definite portion, which is independent of the nature of the substance with which the acid or the base reacts.

Very similar facts may be noticed concerning the other phenomena which accompany neutralisation. A table has already been given (p. 189) showing that the same relations hold good for the changes of volume that accompany neutralisation; the strong acids and bases give, on neutralisation, very nearly the same change of volume, i.e. 20 c.c. per litre of normal solutions of acid and base. The same holds good for the changes in the refractive indices.

The electrical conductivity of electrolytes.—Ohm's law $\mathbf{I} = \frac{\mathbf{F}}{\mathbf{R}}$ gives a definition

of R, the resistance of a conductor. It has been shown that the resistance is dependent on the nature of the conductor, and on its dimensions, in that it varies directly as the length and inversely as the cross-section. It has been agreed to call the resistance of a conductor of cross-section 1 sq. millim, and length 100 centim, its specific resistance; this depends on the nature of the material of which the conductor consists, and on its temperature.

If we define a quantity $C = \frac{1}{R}$, and call it the

conductivity, Ohm's formula becomes I=EC. We may best regard C as the power of the conductor to allow the electricity to pass through, or the power to transport the electricity. In the illustration of a current of water in a tube, C would be comparable to the cross-section of the tube. The conductivity is the reciprocal of the resistance. In calculating the strength of currents it is more convenient to work with resistances; it these are connected end to end, the total resistance is the sum of the individual resistances; but if the resistances are connected side by side, the conductivities must be summed up. For electro-chemical purposes the idea of conductivity has always proved more useful than that of resistances.

Measurements of resistances or of conductivities are made according to different methods, all of which rest on the application of the formula above given. For instance, we can measure the current strength, I, using the same electromotive force E (from a constant cell, as, for in stance, a Daniell), there being included in the

circuit at one time the resistance R, which is to be determined, and at another time a resistance of known magnitude R_o . We then get the equation $I_1 = \frac{E}{R_1} \text{ and } I_o = \frac{E}{R_o}, \text{ and from these } R_1 = R_o \frac{I_1}{I_o}.$ It is not necessary to discuss here the various

methods of measuring resistances. As mentioned before, the unit of resistance used is the ohm-i.e. the resistance of a mercury column of 1 sq. mm. section, and 105 or 106.3 cm. length at 0°. The unit of conductivity is given by the same quantity; since this represents the reciprocal value of the resistance, it has been proposed to designate it by Mho, which is the name Ohm reversed, and for which Mo might be put shortly.

While so far the different powers for conducting electricity possessed by the metals have remained more a question of practical than of theoretical importance, the study of the electrical conductivity of electrolytes has led to most important and suggestive views as to their nature. These have only been arrived at quite lately, chiefly because until recently there existed no convenient and good method for determining the conductivities of electrolytes in solution.

The difficulty to be surmounted consists in the fact that the current must be conducted through the electrolyte by means of electrodes, and that these get coated with the ions which separate-i.e. they become polarised. In consequence of this the electrodes become the seat of new electromotive forces, the magnitude of which is variable, and therefore not capable of being determined exactly. One method only has been brought forward as yet in which this difficulty is completely obviated; it is due to Guthrie and Boys (P. M. 1880. 328), and consists in allowing a system of strong magnets to rotate rapidly round the axing a cylindrical vessel filled with the electrolyte and suspended by a long thin wire. By this means currents are produced in the electrolyte (as would be produced in every conductor), the electrodynamic effect of which tends to rotate the vessel in the same direction. The strength of these currents is proportional to the conductivity of the liquid, and the vessel is rotated until the torsion of the suspending wire becomes sufficient to maintain equilibrium against this rotatory effect. We are therefore justified in putting the deviation as proportional to the conductivity, the velocity of the magnets remain. ing the same. As the currents produced in the electrolyte occur exclusively within it, no polarisation is possible. The method has not been applied, because the apparatus required is expensive and difficult to handle.

Becquerel and Horsford tried to bring up polarisation to its highest value by using strong currents. In this method the current is led through the electrolyte, then through an adjustable resistance, and finally through an instrument for measuring currents (galvanometer, &c.), and its strength is determined. The distance between the electrodes is noxt decreased by an accurately measured amount, and resistances are inserted until the strength of the current has regained its value; then the resistance inserted is aqual to that possessed by the portion of the liquid taken out. The method suffers from the

disadvantage that it is difficult to keep the electromotive force of polarisation constant as presupposed; and, further, the liquid is changed at the electrodes by the use of the stronger currents required, so that what we measure is the resistance of the changed, and not that of the original, liquid.

By using electrodes of zinc, which in solutions of zinc salts give no polarisation, Beetz (P. 117, 1) was able to determine the conductivities of such solutions by the methods used for metals. Paalzoff showed (P. 136, 489) that the method can be applied to other solutions also if we bring the two zinc electrodes into two separate vessels, and establish conduction through a syphon filled with the liquid to be investigated. The process is based on the fact that no polarisation is produced when a current is passed through

the surface of contact of different liquids. But this method is again far surpassed in convenience by one given by F. Kohlrausch (W.11, 653), in which polarisation is made harmless by using alternating currents. Such currents, in which equal quantities of electricity flow alternately in opposite directions, are produced most easily by means of an ordinary induction apparatus. It is true that by such currents the electrodes are also polarised, but the polarisations occur rapidly in opposite directions, sothat the polarisation produced by the first current-impact increases the strength of the second current-impact which has the opposite direction, and the polarisation resulting from the latter adds itself on to the third current-impact, and so on. Kohlrausch has shown that by using platinum electrodes of ten sq. cm. surface coated with platinum black, the effect of polarisation may be reduced to less than 0.1 p.c. of the resistance. Kohlrausch uses for his method Wheatstone's bridge in Kirchhoff's arrangement. For details reference is made to Kohlrausch's memoir.

The definition of specific conductivity as given above, and as employed in physics, is not of practical use in considering electrical conductivity from the point of view of the chemist. Since, according to the law of Faraday, the ions alone conduct, and since each ion carries the same quantity of electricity, it is evident that the conductivities of different solutions must be referred to the same number of ions in order to obtain comparable numbers. That we may form a conception of equivalent conductivity following from this, let us imagine two electrodes of indefinite extension placed at a distance of 1 cm. apart, and let there be brought between them so much of a solution as contains the equivalent weight in grams of the dissolved electrolyte; the conductivity of such a system is the equivalent conductivity of the electrolyte. In order to find the relation between the specific and the equivalent conductivity, we bear in mind that the length of the solution of the electrolyte is 106 times less than 106 cm., which was the length of the conductor assumed in the definition of specific conductivity. When the solution is normal-i.e. contains one g. equivalent per litre—the cross-section is 1,000 sq. cm.; when the same weight is dissolved in v litres it is 1,000v

A detailed description of the method for carrying out such measurements is to be found in Z. P. C. 2, 868.

sq. cm.; this is 100,000v times greater than the cross-section for the specific conductivity, which is '01 sq. cm. Hence from the specific conductivity we obtain the equivalent conductivity is by the equation $\lambda=1.06\times10^{7}lv$. It should be remembered that the specific conductivity of an electrolyte is not usually referred to ohms, but to the unit of Siemens, formerly commonly employed, which is equal to the resistance of a column of mercury 100 cm. in length; hence instead of 106 we must put only 100, and the equivalent conductivity becomes $\lambda=10^{7}lv$.

In addition to the equivalent conductivity we can calculate the molecular conductivity, which is as many times greater than the equivalent conductivity as the molecular weight contains the equivalent weight. So the molecular conductivity of sulphuric acid is twice as great as the equivalent conductivity, that of aluminium

chloride three times as great.

For the general facts which have been established regarding equivalent conductivities we are specially indebted to Kohlrausch, and to several investigators who succeeded him. The most simple relations are exhibited by dilute solutions in which v is greater than 1 lit., and those will be considered first.

1. The equivalent conductivities of normal salts are of the same order of magnitude, but are not the same (Kohlrausch).

2. The conductivities of all salts increase slowly with increase of dilution, and generally reach a maximum value, which is not surpassed after dilutions of 20,000 to 50,000 litres per gram-equivalent (Koblrausch).

3. The increase of conductivity is least for salts which consist of two monovalent ions; it is about twice as great for salts which contain one divalent and one monovalent ion; and about four times as great for salts whose ions are both divalent (Ostwald).

4. The equivalent conductivities of equally concentrated solutions of the most different salts can be represented as the sum of two constants, one of which is determined solely by the positive ion, the other solely by the negative ion (Kohlrausch). This law agrees the better with experience the more dilute the solutions are.

In order to give an illustration of these laws, I append the equivalent conductivities of several normal salts as measured by Kohlrausch. The values are for 18°.

Dilution	KCI	NaCl	Lici	∯BaCl,	1K,80.	iMgSO
17 107 1007 1,0007 10,0007 50,0907 100,0007	91·9 104·7 114·7 110·3 120·9 121·7 121·6	69:5 86:5 96:2 100:8 102:9 102:8 102:4	59·1 77·5 87·5 92·1 91·3 95·5 96·5	65 8 86·1 100·6 109·2 112·6 114·4 114·2•	89·7 109·8 120·7 124·9 126·6 127·5	27.0 47.4 71.5 93.5 103.4 105.2 105.6

If we attempt to form a picture of the processes occurring in electrolytic conduction, we must first bear in mind that, according to the statements of Kirchhoff (P. 78, 506), free electricity must be present along the surface of each current-path; and the fall of this potential causes the motion of the electricity inside the conductor. Hittorf pointed out that the theories of electrolysis hitherto held could not satisfy this requirement. Assuming the presence of free ions,

it is evident at once that the surface charge is formed by these. Owing to the fall of potential which exists, the positive electricity is now driven to the one side, the negative to the other. Both are bound to the ions; which are, therefore, moved in the same way by forces that are of equal magnitudes on both sides.

The velocities acquired by the ions under the influence of these equal and opposite forces will not generally be the same, since it cannot be assumed that the resistances to motion encountered by the ions in the solution will be the same. But in dilute solutions, anylow, the nature of the second ion, travelling in the opposite direction, will have no influence on the velocity of any definite ion—such as, for instance, Cl. Hence the conductivities of salts, when referred to equal quantities of ions, can be represented as the sum of the migration-velocities of the positive and negative ions. Calling these migration-velocities u and v, we get

 $\lambda = u + v.6$ But this is exactly the relation discovered by Kohlrausch (p. 191), to whom also the argument

just given is due.

Viewed thus, the phenomena of electrical conductivity are brought into connection with another group of facts, the comprehension of which had presented great difficulties to the older naturalists. These are the phenomena of the migration of the ions.' It has been mentioned that Daniell observed the corresponding manifestations, but they were not explained till Hittorf did so.

From the table already given it follows that the different ions must possess very different migration-velocities. On comparing, for instance, KCl and LiCl, we find differences of 27 to 30 units. Since the chlorine must possess the same velocity in both cases, and hence participate to the same amount in the conductivity, the difference is due solely to the ions K and Li. In the same manner we can convince ourselves that different negative ions migrate with different

On electrolysing a substance whose ions travel with different velocities, different quantities of the ions will collect at the electrodes, and, in addition to decomposition, the liquid will undergo an unequal change of concentration at the electrodes. In order to get as good a representation as is possible for these relations, let the ions be represented in the figure in the next column by black and white circles. The different horizontal rows represent different phases of the electrolysis, these being such that between them there is a distance equal to the mean distance of the ions. It is assumed that the black ions migrate twice as quickly to the left as the white ones do to the right. At first there are seven ions on each side of the central line. At the end of the process six ions have been liberated at each end, and, in addition, five out of the seven pairs have remained behind at the left side, and two have disappeared; while of the equal quantity at the right side three have remained behind and four have disappeared. Hence the proportion of salt has decreased at the right side twice as much as at the left-that is, in the same ratio as that in which the two ions migrate.

Therefore in order to determine the ratio of

the migration-velocities of the two ions of a salt it is only necessary to determine the proportion of undecomposed salt at each electrode before and after electrolysis; the ratio of the decrease of this proportion at each side is equal to the ratio of the migration-velocities, or is the 'migration-measure.

This representation holds good on the supposition that the ions which separate at the electrodes do not again go into the solution. If, however, we electrolyse a solution of copper sulphate between copper electrodes, the copper, it is true, will leave the solution at the cathode, but the ion SO, will not separate out at the anode, but will combine with the copper of the anode to form copper sulphate, which will go into solution. The solution will, therefore, become, not more dilute, but more concentrated. It is, however, easy to take this circumstance into account. It is only necessary to determine the total quantity of electricity passed through the solution (for instance, by means of a silver voltameter); from this we can calculate how much copper has gone into solution, and we need then only deduct this quantity from the total quantity of copper at the anode, as determined by analysis. It is simpler still to weigh the cathode before and after the experiment: the

increase of weight is equal to the weight of copper which has dissolved at the anode.

Hittorf examined (P. 89 to 106) a great many salts and acids with respect to their 'migrationmeasures,' and established the fact that the current-strength has no influence on the ratio of the migration-velocities, the temperature has an inappreciably small influence, but the concentration exerts a changeable effect-in some cases it is inappreciably small, while in others it is fairly important.

Hittorf found, for instance, that the concentration of KClAq at the electrodes scarcely changes at all; hence chlorine and potassium must migrate with very nearly equal velocities. If we consider the solution v = 1.000l in the table given on p. 191, it follows that of the 119.3 units of conductivity of potassium chloride, 59.65 belong to the chlorine and the same number to the potassium. Knowing these numbers, we can calculate the velocities of migration of all the other ions in the table. NaCl has 100'8; on subtracting from this 59.7 for the chlorine, the velocity of the sodium ion becomes 41·1. Similarly, Li = 32·4, $\frac{1}{2}$ Ba = 49·5. As K = 59·7, and as $\frac{1}{2}$ K₂SO₄ = 120·7, it follows that ${}_{2}SO_{1} = 61.0$; hence ${}_{2}Mg = 32.5$.

From these numbers we can again calculate the migration-measures, or the changes of con-centration at the electrodes, of other salts.

Thus $\frac{\pi}{v}$ is for NaCl = $\frac{41.1}{59.7}$ = 0.69; for LiCl $\frac{32.4}{59.7}$ | preserving very dilute solutions of alkalis perfectly pure. =0.54; for BaCl₂ $\frac{49.5}{59.7}$ = 0.83, &c. It is evident

that when one migration-measure is known, the migration-measures of all corresponding salts can be calculated from the measured conductivities. And since, on the other hand, the conductivities of salts represent the sums of the velocities of their ions, we can realise the very great simplification which these considerations, due to F. Kohlrausch, have produced in the relations of electrical conductivity which formerly appeared so complicated. If, for instance, we know the conductivities of ten salts with the negative ion A and the positive ions B, to B, and of other ten salts with the ion B, and the ions A, to And and in addition to these the migration-measure of one salt, we can calculate from these 21 measurements the conductivities and the migration-measures of 100 salts - that is, we can deduce 200 data.

An extensive examination of these relations, undertaken by Kohlrausch (W. 6, 164), and later by Ostwald (Z. P. C. 1, 74), as well as by Loeb and Nernst (ib. 2, 948), has proved that they hold good with very sufficient accuracy for very dilute solutions. But deviations from these relations become apparent in concentrated solutions, and these leviations are greater the more con-centrated the solutions. And, further, different salts behave differently, inasmuch as salts consisting of two monovalent ions show the smallest deviations, salts with one monovalent and one divalent ion show greater deviations, and salts with two divalent ions show the greatest deviations. Now these are the classes of salts which exhibit differences in the changes of conductivity accompanying dilution (p. 191), and we are, therefore, led to the conclusion that the same cause underlies both phenomena.

The free acids and bases only partially conform to Kohlrausch's law. The following data, taken from Kohlrausch's determinations, exemplify this statement. Temp. = 18°:-

From these measurements it follows primarily that hydrogen and hydroxyl possess much greater migration velocities than the otherions - namely. 284 and about 150, respectively. It follows, therefore, that if the law of Kohlrausch were generally valid, the conductivities of all acids would be > 244. and the conductivities of all bases would be > 150. On looking at the numbers in the table, we find that phosphoric acid and acetic acid, as well as ammonia, are at a quite hopeless distance from these values. Sulphuric acid, also, does not obey the law. For SO, the value 61 0 was found above; on deducting this number from {H,SO, = 331.6, there remains II = 270.6, and the difference of this value from the one found before, 284, exceeds the limits of experimental error.

On carefully studying the table we now see that the acids and bases which form exceptions to the law exhibit the same peculiarity as the exceptional salts; they change their conductivities very markedly upon dilution. While the substances which follow the law have nearly reached the maximum of the equivalent conductivity at 1000/, the numbers show that this is far from being the case in the exceptional substances. We are thus led to inquire as to the cause which brings about the change in conductivity that accompanies dilution.

The arguments used so far have tacitly assumed that all the molecules of the electrolyte participate in the electrical conductivity, and that the electrolyte is therefore completely split into ions. This assumption is evidently arbitrary; and when we remember that aqueous solutions of ammonia and acetic acid exhibit nearly normal lowerings of the freezing-points, and that, therefore, dissociation occurs only to a small extent, if at all, we see that the assumption is completely erroneous in these cases. former equation $\lambda = u + v$, established without reference to the degree of decomposition, must be changed into $\lambda = x (u + v)$ where x represents the degree of decomposition-i.e. the ratio between the molecules decomposed and the total

Dilution	HCI	HNO.	JH,so.	₩,РО,	CH CO, II	Kon	NaOH	NH.OII
12	278·0	277.0	189·9	29·0	1·2	171-8	149·0	0.84
102	324·4	322.5	208·4	43·0	4·3	198-6	170·0	8.1
1002	341·6	339.5	285·5	79·0	13·2	212-4	187·0	9.3
10002	345·6	842.7	831·6	96·8	38·0	214-0	188·0	26.0

Among the substances quoted, HCl, HNO, KOH, and NaOH follow the law of Kohlrausch. Thus, if 59.7, which is the migration-velocity of K, is deducted from 118, which represents the conductivity of KNO, as determined by Kohlrausch, the difference, 583, is the velocity of NO. On deducting this number from the conductivity of nitric acid at 1000l - that is, from 342.7 -it follows that the velocity of hydrogen is 284·4. From HCl = 345.6 it follows that H = 285.9, since Cl = 59.7; these numbers agree to within less than one per cent. In the same way the difference between KOH and NaOH is equal to 26.0, thus approximating to equality with number of molecules orginally present. In doing this we make the most obvious, and probably only possible, assumption, that, cæteris paribus, the conductivity is proportional to the number of conducting particles or ions.

We may find a method for determining a in the deviations of electrolytes from the simple laws of solutions with respect to vapour-pressure and freezing-point. We have another and much more accurate method, however, in the determination of the electrical conductivity itself. As was found by Kohlrausch, the equivalent (and also the molecular) conductivity increases with rising dilution, reaching a maximum value in the that between KCl and NaCl, which is 19.2. The case of salts within limits which are still prac-larger difference proceeds from the difficulty of tically measurable. We can interpret this Vol. IV.

μο

behaviour from the standpoint now gained in the sense that the number of molecules split into ions continually increases with increasing dilution, and that the maximum value of conductivity corresponds to a (practically speaking) complete splitting up. Then x = 1, and the formula $\lambda =$ x(u+v) changes into the former, $\lambda = u+v$. Now, for most salts the maximum value is reached at a dilution of 1000l, and the decomposition is a dilution of 1000s, and the decomposition is nearly complete; it follows from this, that the law of Kohlrausch $\lambda = u + v$ holds good for this maximum dilution. This can be asserted for the strong acids and bases, such as HCl, HNO, KOH, and NaOH. On the other hand, as can easily be seen from the course of the numbers, the increase has not nearly reached its limit for acetic acid and ammonia at a dilution = 1000l: hence the value x is still very far removed from unity, and the law of Kohlrausch cannot hold in its simplest form.

On the assumption that the molecular conductivities of dilute solutions depend only on the number of ions present, the values of x can be easily calculated from a knowledge of the values of the conductivities at different dilutions, as well as of their maximum values; designating the molecular conductivity at the dilution of v litres by μ_{rr} , and the maximum value by μ_{ro} , then, according to the assumption made, v

Whether the above mentioned assumption is strictly correct cannot be asserted a priori. It must be looked upon as probable, since the resistances to motion which the ions experience, and which determine the velocities u and v, depend on the nature of the solvent, which in these cases is water; and considering the small differences which exist between the properties of very dilute solutions and those of water, no appreciable difference in the resistances to motion can be supposed to exist in those differently diluted solutions. But the admissibility of the assumption can also be put to experimental proof in-determining x on the one hand by the deviations from the laws of solution, and on the other hand by the equation just given.

If m_0 is the theoretical molecular weight, and m_0 -the molecular weight determined from the laws of solution (for instance, from the lowering of the freezing-point), then for electrolytes $m > m_0$; following van't Hoff, we put the ratio of

the two $\frac{m_0}{m} = i$. If, on the other hand, x is the

number of molecules split up, the total number of molecules being put equal to 1, and if n is the number of ions into which each molecule splits (for KCl n=2, for BaCl, n=3, &c.), the number of molecules in the solution will have increased in the ratio 1:1-x+nx, that is, in the ratio 1:1+(n-1)x, and we have, therefore, i=1+(n-1)x.

Arrhenius, to whom we owe this calculation,

has shown (Z. P. C. 1, 634) that in the greatest number of cases investigated there is an excellent accordance between the values of as calculated from the electrical conductivities and those deduced from the freezing-points. Individual cases which at first seemed to be exceptions have, on later investigation, also proved to be

subject to the law (Z. P. C. 2, 491), and the apparent deviations have been shown to be due to incorrect observations. It is only at greater concentrations, where the suppositions made in determining molecular weights from the freezing-points, and those made in determining x from the electric conductivities, become uncertain, and not applicable, that marked deviations are apparent.

In addition to this confirmation of Arrhenius assumption that in electrolytes a more or less considerable portion of the molecules is split up, a further confirmation has been found by W. Ostwald, which is based on the following considerations (Z. P. C. 2, 36, and 270). spontaneous decomposition which the electrolytic molecules undergo in solutions is of the nature of dissociation; and since, according to van't Hoff, the substances in solution are subject to the gaseous laws, it must be possible to represent the process by the same formulæ as hold for the dissociation of gases. Considering the simplest case, that each molecule splits into two parts, there holds for gases (vol. ii. p. 406) the relation $\frac{p_2^2}{}$ = constant, where p_1 is the partial p_1 pressure of the undecomposed portion, and p_2 that of the decomposed portion.

In order to apply this equation to electrolytes, we notice that the pressures are proportional to the numbers of the molecules, and inversely proportional to the volumes occupied by these. If x is the part dissociated, and v the volume, then $p_1 = a\frac{1-x}{v}$ and $p_2 = a\frac{x}{v}$; a represents a factor dependent on the units chosen. Further, according to the former equation, we have $x = \frac{\mu_v}{\mu_\infty}$; introducing these values into the dissociation equation, we get $\frac{1-x}{x^2}v = k$, where k is a constant,

and from this
$$\frac{\mu_v^2}{(\mu_\infty - \mu_v)\mu_\infty} = kv$$
.

This equation represents a relation between

This equation represents a relation between the conductivity and the volume, or the dilution, which must be followed by all binary electrolytes, if the assumptions made are correct.

The equation cannot well be tested in the case of salts, as these very nearly reach complete decomposition; the value $\mu_{\infty} - \mu_{\nu}$ thereby becomes very small, and the experimental errors exert a preponderating influence. Those electrolytes which are only partially dissociated, such as acetic acid &c., lend themselves much better to applying the test. Here also it seems as if a difficulty met us, the quantity \$\mu_{\infty}\$ not lending itself to direct measurement because, with the very great dilutions necessary, the inevitable impurities of the purest water make accurate measurements impossible. But the law of Kohlrausch provides us with a means for making the measurements. It appears that the salts of weak acids are dissociated to just the same extent as those of strong acids; it is possible, therefore, as was shown at pp. 192-8, to calculate the migration-velocity of the negative ion. On adding to this the migration-velocity of hydrogen. which can also be determined (p.493), the sum represents the conductivity of the completely

discociated acid—that is, μ_{∞} , the quantity sought (Ostwald, Z. P. C. 2, 840).

In this manner, then, we obtain all the data for testing the above equation, and it proves itself to be in direct accordance with the facts. The examination is best carried out by calculating the constant k for a number of values of \(\nu\) at different dilutions, and seeing whether it really is constant. In the following tables a few examples are given. The numbers hold for 25°, and are molecular conductivities referred to the mercury unit:—

Acetic acid, $\mu_{20} = 364$.

0	μ	100 <u>μ</u>	Ł
8	4.34	1.193	0.000180
16	6.10	1.673	179
32	8.65	2.380	182-
64	12.09	3:33	179
128	16.99	4.68	179
256	23.82	6.56	180
512	32.20	9.14	180
1024	46.00	12.66	177
			0.000180

The values of k, calculated from eight different measurements, agree within the limits of experimental error.

The osmotic pressure of acetic acid at v=8 corresponds to about three atmospheres, that at v=1024 to about $\frac{1}{45}$ atmosphere, or to 1.7 mm. mercury pressure. The dissociation law has, therefore, proved correct within these wide limits; no examination of the law so farreaching as this has ever been possible in the case of gases.

Further examples are: -

Cyanacetic acid, $\mu_{\infty} = 362$.

			0.00370

Here also the individual values of the constant vary irregularly about the mean value, so that the discrepancies have to be ascribed to experimental errors.

In the accompanying tables, which have been taken at random from a great number, the dissociation law proves itself everywhere to be accurate. It has, in fact, been verified in every case in the course of an investigation which, for reasons to be discussed later, has been carried out with more than 400 acids, and it can be looked upon as generally valid.

We must not omit to remark, however, that, as observed above in the cases of the very strong

Oxyisobutyric acid, $\mu_{\infty} = 855$.

acids, and the neutral salts, which are very nearly completely dissociated, the calculation of the constants becomes very uncertain, and that greater deviations exist between the observations and the formula than can be ascribed to experimental errors. Which of the assumptions already made will have to be modified in order to explain these small discrepancies cannot as yet be determined; but anyhow the discrepancies are so inconsiderable, and there are so many cases of agreement, that the deviations must be looked upon as of a secondary nature, and undoubtedly they will receive their explanation later on. It is well not to pass over in silence, nor to attempt to hide, such deviations from a law which is otherwise generally valid, since in most cases theoretical progress is connected with the investigation of the causes of deviations from general laws. Examples of this are found in the deviations of gases from the sin ple laws, and the theory connected with this by van der Waals, and in the deviations of some substances from the law of Avogadro and the elucidation thereof by the theory of dissociation.

Chemical applications.—The laws of electrical conductivity, as developed in the preceding pages, give us the means for solving many chemical problems. This they do, because they ive a deeper insight into the constitution of issolved substances than is afforded by the sual chemical methods. A series of such appliations is already contained in the preceding ages; others are considered in the following aragraphs.

The first of these applications is connected vith the question as to the nature and composiion of the current-conducting particles or ions of salts. The conception of Berzelius that these re the 'anhydrous' acid and base has, in the ight of Faraday's law, been recognised as erroieous. Afterwards, in analogy with the comounds of organic chemistry, the salts were looked ipon as having a unitary composition, and this riew is still generally held. But this conception cannot be regarded as quite correct, since it does not take into account the fundamental difference which undoubtedly exists between salt-like compounds and indifferent compounds, a difference which manifests itself chiefly in the capacities for reaction of the two groups. The conception of Berzelius rested on the correct recognition that salts are dual compounds; he had only misconceived their constituents.

The new electro-chemical theory of Arrhonius avoids both errors, and retains what is correct in each conception. The solid salts, and, according to concentration, a greater or smaller portion of the salts dissolved in water, 'salt' being understood to include acids and bases, have, it is true, a unitary composition; but that portion of them which is capable of reacting chemically, and which therefore is of preponderating interest to the chemist, is split binarily.

'Salts,' in the general meaning, are therefore substances which very readily undergo such a binary splitting, and herein lies their binary character, correctly recognised by Berzelius.

It is a most remarkable fact that in the splitting up of 'salts' their constituents appear in oppositely charged electrical conditions. This indicates that probably both phenomena stand in the closest connection. It may be asked whether the salts split up so easily because their parts readily acquire opposite electric charges, or, conversely, whether the parts are easily charged electrically because they are readily separated. Not less remarkable is the fact that whenever a salt molecule is split up an equal quantity of electricity is produced (or separated), independently of the nature of the parts. It is beyond doubt that this fact is of decisive importance for the recognition of the nature of electricity, as well as of that of chemical affinity; when the one is elucidated, the other will be so also. But which of the two will first be thus advanced cannot as yet be foreseen.

A further remarkable fact is, that pure salts at ordinary temperatures do not conduct appreciably; the ordinary solid salts do so as little as pure sulphuric acid, acetic acid, &c. Even the halogen acids HF, HCl, HBr, and HI, when liquefied by pressure or cold, are all non-conductors. According to the dissociation theory of electrolytes this is quite comprehensible; the pure substances do not conduct because they are not dissociated, and they are not dissociated because their molecules have no space wherein to dissociate, or because they do not possess sufficient mobility.

Whether dissociation occurs or not when salts are dissolved depends in a marked way on the nature of the solvent. Hydrochloric acid, which when liquid is not dissociated, dissociates at once when dissolved in water. But on using as solvent benzene, xylene, hexane, or ether, no dissociation ensues; these solutions are non-conductors (Kablukoff, Z. P. C. 4, 480). On using alcohols as solvent, methyl alcohol is found to behave almost like water; the solutions of hydrochloric acid in if have a molecular conductivity about three times smaller than aqueous solutions. The conductivities of the solutions become less and less as we use ethyl alcohol, isobutyl alcohol, and issantyl alcohol.

It is still quite unknown what the condition is which determines the property of different solvents to cause dissociation to a different degree, and it is not known whether, as is somewhat probable, these effects remain proportional in the cases of all salts. Here it seems, however, as if the capability of the solvent itself to separate into ions, even if to a small degree only, determined its power to cause the dissociation of substances dissolved in it.

Although the questions just mentioned still await solution, partly for lack of experimental researches in this domain, yet the new conception of the binary character of salts allows us to distinguish more sharply between the different classes of these compounds than was possible before. This is especially so in the case of the so-called double salts. This name is at present somewhat uncertain in its application. Potassium copper sulphate K2SO1.CuSO1 is called a double salt, but sodium platinichloride is also formulated as such, 2NaCl.PtCl.; the first formula is correct, but the latter is wrong. This is so because potassium copper sulphate gives all the reactions of potassium sulphate as well as those of copper sulphate, but from sodium platinichloride silver solutions do not precipitate silver chloride as from sodium chloride, but silver platinichloride Ag, I'tCl. (Jörgensen, J. pr. [2] 16, 345). It is probable, therefore, that sodium platinichloride is a salt of chloroplatinic acid H.PtCl_g. If this is correct, the ions of the sodium salt are 2Na and PtCl_g, and in electrolysis the platinum must not, like the other metals, go to the cathode, but as a constituent of the acid radicle to the anode. And, in fact, Hittorf has proved (P. 106, 520) that this is the case.

Similarly with other salts; for instance, that which is obtained from chromium oxide and potassium binoxalate, and which has the empirical formula 3K₂C₂O₄Cr₂(C₂O₄)₃. Since this salt gives no pp. with calcium salts it cannot be regarded as an oxalate. In fact, in electrolysis the chromium goes to the anode; the chromium is, therefore, a constituent of the acid radicle, and the salt must be looked upon as the potassium compound of a tribasic chromoxalic acid (HC₂O₄)₃Cr—that is, as K₁C₄O₁₂Cr (Kistiakowsky, Z. P. C. 6, 107).

Such salts, therefore, are not double salts, but are salts of complex acids; it is possible to test, in the way already indicated, in every cas, whether a definite salt is a true double salt or the salt of a complex acid. One xamination we find that, not a double salt, but a salt of a

complex soid is present whenever the reactions of the salt in question are not those of its constituents. This decision is specially convenient when the solution of the salt is coloured. Because, since the properties of the positive ions, and therefore their colour also, are independent of the negative ions, it will always be possible to conclude that the positive ions are no longer present when their colouration disappears. In the easily decomposable salt 2KCN.Ni(CN), we must not see a double salt, but the potassium salt of cyano-nickelic acid H₂Ni(CN), because its solution is yellow, and not green as solutions of the nickel salts are which contain nickel as an ion.

The line of demarcation between the two groups of salts, however, is not absolute, as many salts exist which in aqueous solutions are both double salts and also complex ones. This is the case with potassium ferri-oxalate, for instance. Since this salt is green, while all true ferric salts are yellow or brown, it may be concluded that it is a complex salt, the compound of a ferri-oxalic acid H, C,O12Fe analogous to the above-mentioned chromo-oxalic acid. The solution of this salt gives, however, a precipitate with calcium solutions, which proves it to be an ordinary oxalate, but on the other hand the iron goes to the anode. From this it is seen that the aqueous solution contains chiefly the ions 3K + C_sO₁₂Fe, but that a portion of the salt has split in the manner of a double salt into potassium oxalate and ferric oxalate, which on their part form the corresponding ions.

The study of such cases has as yet scarcely been begun, because until now we possessed neither theoretical nor experimental means for answering the questions which arise. The electrical methods, in conjunction with the methods for the determination of molecular weights arising out of the theory of solutions, flow afford casy access to these hitherto closed and uncultivated domains.

The dissociation-constants of organic acids. The only province of chemistry which has been studied somewhat thoroughly in the light of the new electro-chemical theory is that of the organic acids. We have seen above that the molecular conductivity of these can be

represented by the formula
$$\frac{\mu_v^2}{(\mu_{\infty} - \mu_v)\mu_{\infty}} = kv$$
.

This formula contains only the single constant k, which constant depends on the nature of the acid, the temperature, and the solvent, but is independent of the dilution. At a given temperature, and in the same solvent, the quantity k is therefore a measure of the electrical conductivity, and hence it is the capacity for reaction of the acid; for the substance considered, k therefore represents the long sought for numerical value of the chemical affinity.

It is remarkable that the two conflicting views concerning the nature of chemical affinity, as represented by Bergmann and Berthollet (cf. vol. i. 68) here coincide. Berthollet, who represented the affinity as dependent on the mass, was right, and so was Bergmann, who desired to represent it by a constant. By accurately formulating the idea of the influence of mass as given by Berthollet, we obtain in the equation for the

chemical effects a co-efficient independent of the quantity—that is, one referred to the chemical unit of quantity, which is Bergmann's measure of chemical affinity.

of chemical affinity.

It has already been shown (vol. i. 81) that the electrical conductivities bear a definite relation to the composition and constitution of the acids. But the law of dissociation of electrolytes had not been discovered at the time when the article referred to was written, and the observed relations could not be represented numerically. This has now become possible, by means of the vaffics of the constant k, which have been measured for about 400 acids (Ostwald, Z. P. C. 3, 170; Bethmann, ib. 5, 885; Bader, ib. 6, 289).

Before expounding these relations, it will first be shown how the laws which have been found empirically for the electrical conductivities follow directly from the above dissociation-formula. In order to make the consideration easier, the formula will first be somewhat simplified by substituting for the molecular conductivity μ_{ν} its value referred to the maximum $\frac{\mu_{\nu}}{\mu_{\nu}} = m$.

The equation then assumes the simple form $\frac{m^2}{1-m} = kv.$

In the first place, we see that as the dilution v increases infinitely, the quantity 1-m must approach zero. Hence m must approach unity; hence the electrical conductivity increases with dilution up to a maximum, as has been shown by experience.

Further, it was found that when at any dilutions, v_1 and v_2 , two different acids have the same (relative) conductivity, they also have the same at other dilutions v_1 and v_2 , as long as the new dilutions are in the same ratio as the old ones—that is, when $v_1: v_2=v_1': v_2'$. This follows from the formula in this way: on the supposition that the relative conductivities are the same,

we have first of all
$$\frac{m^2}{1-m} = k_1 v_1$$
; $\frac{m^4}{1-m} = k_2 v_2$;

therefore $k_1v_1 = k_2v_2$. And in the same way for the other dilutions, $k_1'v_1' = k_2'v_2'$, from which it follows directly that $v_1: v_2 = v_1': v_2'$.

In addition, F. Kohlrausch had already pointed out that in the cases of acids which conduct badly (which, therefore, are but little dissociated), the molecular conductivity increases nearly as the square root of the dilution. If in the equation $\frac{m^2}{1-m} = kv, m \text{ is very small, } 1-m \text{ differs little}$

from unity, and can be looked upon as constant; then approximately, $m^2 = kv$, or $m = \sqrt{kv}$.

Finally, on taking the logarithms of the dilutions as abscissmend the values of m as ordinates, we also get from the formula a curve resembling a tangent-function (vol. i. page 82); the interpolation-formula given in vol. i. must be replaced by the present rational formula.

As regards the meaning of the constant k, we recognise what this is on putting m = 0.5, when we get $2k = \frac{1}{v}$. 2k is therefore the reciprocal value of the volume, or the concentration at which the electrolyte is just half dissociated. This number is extremely characteristic for different contents of the concentration of the concentration at which the electrolyte is just half dissociated.

ferent acids, since its value may vary according to the nature of the substance between the limits 1 and 1,000,000.

The measurement of the quantity k for differacids has led to the following general law:— The constant k is approximately the product of a number of factors, each of which depends on the nature of the constituents of the acid and on their. position relatively to the carboxyl group.

In order to realise what this law implies, and in what manner it is applied, we will proceed to discuss in the following pages the most important groups of the organic acids. The relations, the main features only of which could formerly (vol. i. page 82) be investigated, can now be represented numerically with perfect exactitude. The numerical values for k have been multiplied by 100 in order to get rid of ciphers; they all hold for aqueous solutions at 25°.

The fatty acids. The following constants were measured:—

Formic acid has the highest constant; the replacement of its hydrogen by methyl reduces the constant to half its value. But on again replacing one hydrogen atom in acetic acid by methyl the constant only decreases to $\frac{1}{1.4}$ of

its value, and further similar substitutions no longer produce a weakening of the acid, but some of them even bring about a slight strengthening. These changes are, however, but small, so that the constants of acids of this sories having more than three carbon atoms vary irregularly about the mean value 0.0014.

It is evident, then, that the substitution of hydrogen by methyl acts quite differently, according as it occurs next to the carboxyl or at a greater distance from it. This is a result which will atterwards be shown to hold good in all cases; on the whole, the effect of each substituent is the smaller the more distant it is from the carboxyl. The inference that the interposition of even two carbon atoms nearly counteracts the effect is correct for methyl, for which it is relatively small. Other constituents of greater energy extend their action further, but yet not over more than three or four atoms of the 'open chains'; in the case of 'closed chains' other relations hold good.

Halogen derivatives of the fatty acids. The entrance of chlorine in the place of hydrogen in the fatty acids exerts very considerable influence. The constants are—

1:86:2840:67200. The ratio of the values of the constants for the different acids, referred to the entrance of each separate chlorine atom, is 84, 33, and 24. It is only the ratios of the constants, and not their differences, which are

important; the ratios, though not equal, are yet of the same order of magnitude, while the differences between 0.155, 5, and 121 are quite incomparable. Further, it follows that the relative change of the constants for the entrance of each chlorine atom is not of the same value; the first chlorine atom acts more intensely than the second, and the second more intensely than the third. We shall again meet with a similar relation when dealing with substitution in connection with the same carbon atom. From this it may be concluded that the first chlorine atom which enters into acetic acid exerts its influence under more favourable conditions, therefore probably from a less distance, than the second and third, and it becomes evident how well such measurements lend themselves to investigations and examinations of the relations in space of the atoms within the molecules. The action of other elements and radicles is very similar to that of chlorine.

Monobromacetic acid CH_Br.CO_H . 0.138 Cyanacetic acid CH_CO.H . 0.370 Thiooyanacetic acid CH_SCN.CO_H . 0.265 So-called 'carbamine thioglycollic acid 'CH_(SCONH_)CO_H . 0.0246 Isothiocyanacetic acid C_1H_O_S.N . 0.0000246 Thiacetic acid CH_COSH . 0.0469

The constant of monobromacetic acid does not differ much from 0.155, that of monochloracetic acid, hence both halogens exert about the same influence. Cyanogen acts much more intensely. The ratio of cyanacetic acid to acetic acid has risen to 205 (from 86). Thiocyanacetic acid also is stronger than monochloracetic acid. but not so strong as cyanacetic acid, though sulphur is generally a negative substituent-that is, one which augments the acid properties. The idea of relations in space at once suggests itself; by the introduction of sulphur there has, in fact, taken place, on the one hand, an increase in the acid properties, but on the other hand, since the cyanogen is removed to a greater distance from the carboxyl, there has been a weakening, and the latter effect preponderates over the former. By taking up water, thiocyanacetic acid easily passes into the acid CH. SCONH, CO.H, the group CN changing into CO.NH. This transformation is accompanied by a marked decrease in the conductivity, the constant falling to less than a tenth of its former value: The change can be conveniently studied in an aqueous solution of thiocyanacetic acid, by determining its electrical conductivity; the conductivity decreases continuously, and after even a few days the greater part of the thiocyanacetic acid is found to be changed. Finally, there is a compound isomeric with thiocyanacetic acid, which Volhard (J. pr. [2] 9, 6) obtained by the action of hydrochloric acid on sulphohydantoin, and which is isothiocyanacetic acid. The constant for this compound is 10,000 times smaller than that for thiocyanacetic acid; it is also smaller than that of any other carbon acid, so that the inference must be drawn that the substance is not a carbon acid at all. This confirms the view expressed by Liebermann, and the reasons for which were given by Hantzsch (B. 20, 3129), that the compound is a dioxy-

The feebly acid properties are ascribed to the hydrogen of the innide group. The thiacetic acid mentioned at the end of the last table contains sulphur in the place of oxygen in the hydroxyl of the carboxyl. In accordance with the negative nature of sulphur, this acid proves to be twenty-six times stronger than acetic acid, and this factor may be looked upon as the greatest to which sulphur can give rise when replacing oxygen, because in this case the sulphur atom acts from the most favourable position which is ever possible.

Oxyacetic acid and its derivatives.

Glycollic acid CH, OH.CO, H	0.0152
Methoxy-acetic acid CH, (OCH,)CO,H	0.0335
Ethoxy-acetic acid CH2(OC2H3)CO.H	0.0234
Phenoxy-acetic acid CH2(OC,H3)CO2H	0.0756
Glyoxylic acid CH(OH), CO, H	0.0474

The replacement of hydrogen by hydroxyl in acetic acid produces a rise in the constant of 9 times its former value; hydroxyl, therefore, acts much less intensely than the halogens. By introducing a second hydroxyl the constant again becomes greater, but only 3.1 times greater. Here we find quite the same effects as in the cases of mono- and di-chloracetic acid, the second substitution of the same substance acting less strongly than the first. In the numerical values, even, we cannot overlook a certain correspondence; in the case of chlorine the ratios are 1:86 and 1:33; in the case of hydroxyl they are 1:9, and 1:31. It may therefore be said that, using round numbers, in the derivatives of acetic acid chlorine acts ten times as intensely as hydroxyl. When the hydroxylic hydrogen of glycollic acid is replaced by radicles, the constant changes, and, strange to say, methyl acts in this case in a strengthening manner, the constant rising to a little more than twice its former value. The substitution of hydrogen in this methyl by methyl again has a weakening effect, as is the case with the fatty acids; ethoxy-acetic acid is 1.4 times weaker than methoxy-acetic acid. Finally, by the introduction of phenyl, the constant becomes appreciably greater; it is about five times as great as that of glycollic acid, and is 2.3 times greater than that of methoxy-acetic acid. The ratio is smaller than that between acetic acid and benzoic acid, which is 1:3.3, an indication that the exchange of methyl for phenyl has in the latter case taken place in greater proximity to the COOH group, a con-clusion which follows also directly from the

A number of other substances related to glycollic acid have given the following numerical values:—

vanues:—
Thioglycollic acid CH₄(SH)CO₂H. 0.0225
Thiodiglycollic acid S(CH₂CO₂H), 0.048
Dithodiglycollic acid S₂(CH₂CO₂H), 0.065
Digiycollic acid O(CH₂CO₂H), 0.11
As the constant of glycollic acid is 0152, we

As the constant of glycollic acid is 0152, we see that the substitution of S for O in hydroxyl has caused the constant to increase 1.5 times; now, as substitution of S for O in OOOH of acetic

acid increased k from 1 to 26, we see here also the great influence of the position occupied by the replacing atom.

The three other acids quoted in the last table are dibasic, and the question at once arises how their constants must be calculated, since the dissociation-formula has been developed for binary electrolytes-that is, for monobasic acids only, and not for ternary ones, to which class the dibasic acids belong. It can, however, easily be shown that, as long as the dissociation is not great, the weaker dibasic acids are not electrolysed according to the formula $2H+R^n$, but according to the formula H+HR. In other words, at first one hydrogen atom only is split off, and the dissociation takes place according to the binary scheme of the monobasic acids. This follows from the fact that the change in the molecular conductivity of such acids can be represented by the same formula $\frac{m^2}{1-m} = vk$, so

that k remains constant. But the formula calculated on the assumption of a dissociation according to the scheme $H_1 h^{n_1} = 2H + R$ does not represent the change in the conductivity of these acids as determined by experiment.

Malonic acid CH₂(COOH)₂ may serve as an example of dibasic acids. It gives:—

•		m	100#
16	53'1	0.149	0.159
32	72.3	0.202	0.159
64	97.1	0.272	0.158
128	128.5	0.359	0.157
256	165.9	0.464	0.157
512	208.8	0.586	0.162
1024	253.2	0.708	0.168
2048	294.2	0.823	0.187

The constant does not change till the value m=0.586 is reached—that is, till about half the acid has been dissociated according to the binary scheme; then it becomes greater—a sign that henceforward the formula loses its validity, and that the decomposition according to the ternary scheme 2H+R'' begins to assume an appreciable value.

If, on the other hand, we attempt to calculate the conductivity according to the formula corresponding to ternary dissociation $\frac{m_s}{(1-m)v^2} = k$, the values of k decrease very rapidly and are far from being constant.

The values for the constants of dibasic acids given in the table preceding the last one have been calculated on this principle, and refer, therefore, to the first stage of binary dissociation H.R = HR + H.

H.R=HR+H.

*Comparing thioglycollic acid with thiodigly-collic acid and dithiodiglycollic acid, we find that the constants do increase distinctly, though only slightly; they are 0 v255, 0 048, and 0 065, and are in the ratio of 1:2:1:2.9. When, therefore, the residue of acetic acid, CH_CO_H, enters thioglycollic acid, this process has no appreciable influence on the constant. On the other hand, the constant of diglycollic acid. From the fact that the same substituent produces such different

effects in glycollic acid and in thioglycollic acid, it may be presumed that in the first case the oxygen brings the negative substituent nearer to the carboxyl than the sulphur does in the second case, and this presumption may be further utilised for hypotheses concerning the configuration of the sulphur atom, and the arrangement of the allinity points on it. It has, however, not yet been established with certainty that the greater or less distance of the groups is the only cause of their different actions, and there are some circumstances which allow us to conclude that other conditions are effective also; therefore, until these have been cleared up, conclusions such as the above hold only hypothetically.

Derivatives of amido-acetic acid.

Phenylamido-acetic

acid CH_(NHC,H_)CO_H . 0.0039

Hippuric acid CH_(NH.CO.CH_)CO_H . 0.0222

Aceturic acid CH_(NH.CO.CH_)CO_H . 0.0230

Phthalvlamido-acetic acid

 $CH_2(NC_2O_2C_6H_1)CO_2H$. . 0-100

Amido-acetic acid has not the character of an acid; the basic NH₂ group completely removes the acid properties of acetic acid. But if negative radicles are introduced into NH₂, well defined acids are again obtained. Phenyl has this effect, the constant of phenylglycocoll is 2·2 times as great as that of acetic acid. The constants of the acids obtained by introducing CO.C.H. and CO.C.H. for H in NH₂ are 12 to 13 times greater than that of acetic acid. The substitution of the divalent residue of phthalic acid for the two hydrogen atoms in the NH₂ group raises the constant of acetic acid 55 times.

Derivatives of propionic acid.

Propionic acid CH_xCH_xCO_xH . 0.00134 Lactic acid CH_xCH(OH)CO_xH . 0.0138 β-Oxypropionic acid CH (OH).CH_xCO_xH 0.00311 Glyceric acid CH_xOH.Cli.OH.CO_xH . 0.0228 β-Iodopropionic acid CH_xLCH_xCO_xH . 0.0090 Trichlorlactic acid CCl_xCH.OH.CO_xH . 0.465

The constant of d-oxypropionic or lactic acid is 10 times greater than that of propionic acid, but the constant of \$\beta\$-oxypropionic acid is only 2.3 times greater than that of propionic acid. The difference in the action of the same substituent, according to its nearer or more distant position relatively to COOH, asserts itself most clearly. The ratio between propionic acid and lactic acid is slightly greater than that between the analogods substances acetic acid and glycollic acid (1:9); it is, therefore, not quite immaterial whether the substitution does or does not take place in the group CH3. influence of the more distant position of the substituent can be recognised in \$\beta\$-iodopropionic acid and trichlorolactic acid. The first is only 6.5 times stronger than the parent substance. No measurement of α-iodopropionic acid has yet been made, but there is little doubt that iodine In the α- position must act very similarly to chlorine or bromine, and must, therefore, increase the sonstant by 70 or 80 times. The effect in the 3- position is 10 to 12 times less than this. the same way the substitution of 3Cl for 3H in 3H2.COOH increases k about 67,000 times; but he introduction of 8Cl into CH, CHOH.COOH n the β - position increases k only about 33-7

times. The ratio of these effects is about 1:2000; calculated for each Cl atom the ratio is $\frac{\sqrt[3]{2000}}{2000} = 12.6$; this ratio comes very near that estimated for α - and β -iodopropionic acids.

Derivatives of higher fatty acids.

Oxylsobutyric acid (OH₂)₂CH.OH.CO₂H 0-0108

Mononitrocaproic acid O₂H₁₀(NO₂).CO₂H 0-0123

Dinitrocaproic acid O₂H₁₀(NO₂)₂CO₂H . 0-069

Lævulinic acid CH₂CO.CH₂CH₂CO₂H 0-00255

Since the constant of isobutyric acid is 0.00144, the hydroxyl in the a-position here causes the factor 7.4, whigh is somewhat smaller than 9, the corresponding ratio between acetic acid and glycollic acid.

The ratio between caproic acid and its mononitro-derivative is 1:8.5. Since, as will soon be shown, the nitro-group has a more strongly negative action than chlorine, NO₂ must, in the present case, be in the \$\beta\$- position. The same holds for the dinitro-compound; it is 5.6 times stronger than the mononitro-compound; it is again evident that the second negative group has less effect than the first.

Levulinic acid, or β -acetyl-propionic acid, allows us to recognise the smaller influence to be expected of the acetyl in the β - position; the constant is only 1.9 times larger than that of propionic acid.

Benzoic acid and its derivatives. The largest and most varied group of allied substances that has been investigated so far, is that of benzoic acid and its derivatives, and consequently it has been possible to trace here many and striking regularities.

acid [1:2:4:6] C,H,(OH),CO,H 2·1

The numbers indicate the positions of the OH groups relatively to COOH supposed to be in position 1.

This table contains the constants of all hydroxyl-benzoic acids known up to the present time. These show such close connections with the their that, knowing the constants of benzoic each of the three monoxybenzoic acids, those acid and of the can be calculated approximately. of all the other can be calculated approximately. It is true the constitutions of the constants of the constants of the constants.

Between the consuche ratio is 1:17. This value ortho-oxy-derivative $t_{i,0}$ when OH is introduced is larger than the ratio, $t_{i,0}$ when OH is introduced in the a-position into red 10; in the β -position, the ratio did not exce he constitution of salicylie which corresponds to $t_{i,0}$ larger than 2.3. From this acid, the ratio was not larger than 2.3. From this

it appears that the ortho-position involves a much closer relation in the benzene nucleus than even the a- position in the open chain, a fact which later on will be confirmed in many ways, and which seems to be of great importance in dealing with the question concerning the constitution

of benzene.

The constant is increased but slightly by OH in the meta-position. But in the para-position the hydroxyl even produces a diminution of the constant to rather less than half the value. We deal in this case, therefore, not only as usual with a greater or smaller value of the influence exerted by a substituent according to its position, but with a reversal of the direction in which the influence is exerted. This fact, which has already become evident in the case of methyl, recurs with other feebly negative substituents in the paraposition of the benzene nucleus. This promises to become very important in the construction of a theory to explain these phenomena.

We have then the following factors for the

influence of the hydroxyl :-

Ortho 1:2 or 1:6 = 17 Mota-1:3 1:5 = 1.4 •• 1:4 = 0.5Para-

By their help we are able to calculate the constants of the di- and tri-oxybenzoic acids by multiplying the constant of benzoic acid by the corresponding factor for every hydroxyl intro-duced. It must be remembered that such a calculation can only give approximate results; for we have seen that substituents already present some-what influence the magnitude of the factor of a newly entering substituent, and that, generally, by decreasing it. It is, therefore, only the order of magnitude of the constants, and not their exact value, that we shall be able to find in the manner indicated.

Four dioxybenzoic acids can be derived from salicylic acid; the constants of these four acids are calculated thus :-

```
1:2:3 gives .0060 \times 17 \times 1.4 = 0.143
1:2:4
                 0060 \times 17 \times 0.5 = 0.051
                 0060 \times 17 \times 1.4 = 0.143
1:2:5
         ,,
                 .0060 x 17 x 17 = 1.73
1:2:6
```

The numbers observed are 0.114, 0.052, 0.108, and 50. In the case of the first and the third acid which both contain a hydroxyl in the m-position, a diminution of the combined effect therefore makes itself felt as usual. In the second acid 1:2:4, calculation and experiment completely agree; while the fourth acid 1:2:6, which contains two ortho- hydroxyls, shows a value about three times greater than is furnished by the estimation. We shall see later that this behaviour is common; two substituents in the orthe position do not, as is otherwise usual, weaken one another, but reinforce each other's

For the two dioxybenzoic acids still remaining we must expect the following constants:

```
1:3:4 gives .006 \times 1.4 \times 0.5 = 0.0042
1:3:5
          " .006 \times 1.4 \times 1.4 = 0.012
```

Measurement gives 0033 and 009, both constants being therefore as usual somewhat smaller, a consequence of the combined effect, yet being quite of the expected order of magnitude.

The six possible trioxybenzoic acids allow us to estimate the following constants:

```
1:2:3:4 gives .0060 \times 17 \times 1.4 \times 0.5 = 0.07
                 .0060 x 17 x 0.5 x 17 = 0.9
1:2:4:6
1:3:4:5
                 ·0060 × 1·4 × 0·5 × 1·4 = 0·006
1:2:3:5
                 ·0060 × 17 × 1·4 × 1·4 = 0·2
          ••
                *0060 × 17 × 0.5 × 1.4 = 0.07
1:2:4:5
1:2:3:6
                0060 \times 17 \times 1.4 \times 17 = 2.4
```

Of the six possible trioxybenzoic acids three are known and measured. The comparison between the observed and estimated constants gives 0.055 instead of 0.07; 0.004 instead of 0.006, where as usual the observed value is smaller than the estimated value; and in the case of the acid with two hydroxyls in the ortho-position we have 2.1 observed instead of 0.9 estimated, which therefore, as before, is about twice as great. In the same way we may expect in the cases of the three trioxybenzoic acids still unknown, that the real constants of the acids 1:2:3:5 and 1:2:4:5 will be somewhat smaller than the estimated values, and therefore about 0.15 and 0.05, while the third acid 1:2:3% with two ortho- hydroxyls will probably have a constant from 5 to 5.5. spite of the uncertainty of the estimation, the differences are so considerable that when in future one of these acids is prepared the determination of the conductivity of an aqueous solution will suffice to decide its constitution.

The constitutional relations of the oxybenzoic acids, as indicated by the dissociation constants, are therefore in complete agreement with those

deduced from chemical relations.

The methods just expounded may be directly utilised for elucidating constitutional relations. On heating orcin C_aH₂(OH),CH, with KHCO_a there is formed 'paraorsellic acid,' whose constitution must correspond either to that of a- or \$-resorcylic acid. On measurement, the constant appeared to be 4.1; the acid has, therefore, a constitution analogous to that of a-resorcylic acid, corresponding to the arrangement CO,H:OH:OH:CH, = 1:2:6:4.

Further substitution products of benzoic acid gave the following numbers:-

The same conclusion may be drawn from these numbers as to the influence of the halogens as had been deduced for hydroxyl-namely, that the ortho-position is that of greatest influence. The constant of benzoic acid rises to 22 times its value on the introduction of chlorine in the ortho-position, to 2.6 times its value when Cl is put in the meta-position, and to 1.5 times its value when Cl is put in the para- position. But along with this there is a remarkable difference between the behaviour of OH and that of Cl; hydroxyl acts much more strongly in the orthoposition of the benzene nucleus than in the a- position of the open chain, while chlorine, which in the a-position of the open chain in-creases the constant to more than 80 times its value, does so only 22 times when in the of thoposition in the benzene nucleus. For this discrepancy the explanation offers itself, on the one hand, that the system of carbon atoms which constitutes the benzene nucleus is not rigid, but alters its form according to the atoms present in it, and that if so, the difference in form must be especially great according as hydroxyl or chlorine enters near the carboxyl. On the other hand, the following possibility strikes us. According to the hypothesis of Kekulé, there are two sorts of ortho-positions, the one being represented by a double, the other by a single, linkage. Now it is quite possible that in benzene itself the change of the double or single linking to the right or the left takes place easily, but that when two adjoining carbon atoms have fixed different atoms or groups of atoms, only one sort of linkage, either a single one or a double one, is stable. Assuming that -in salicylic acid, for instance-double linkage exists between the carbon atoms, combined with COOH

carboxyl and hydroxyl respectively,

while in o-chlorobenzoic acid the single linkage

only is stable, CCl , the difference empha-

sised above can be understood, since in the first case the ortho-relation is a much more intimate one than in the second.

The small changes which the constant of benzoic acid undergoes in m- and p-chlorobenzoic acid correspond to the greater distance of the chlorine from the carboxyl. According to the usual representation of benzene, the influence of the para-position proves to be the smallest. But this behaviour is by no means general.

Bromine behaves very similarly to chlorine. The effect for the ortho-position is somewhat larger than for chlorine—i.e. 24 instead of 22; that for the meta-position somewhat smaller—2-3 instead of 2-6.

When hydrogen in gallic acid is replaced by bromine in the ortho-position, the constant increases to 15 times its value, therefore less than in the case of benzoic acid. This corresponds to the general rule that several substituents simultaneously present diminish each other's action. Only when two substituents, which are the same, occupy the ortho-position is an increase in the simultaneous effect to be observed; in fact, a second bromine atom which occupies the ortho-position brings about a greater rise of the constant than does the first —21 instead of 15.

Hydrofluor cacid being much weaker than hydrochloric acid, it was to be expected that the fluobenzoic acids would be weaker than the chlorobenzoic acids. In case of the meta-compound this occurs, however, only to a small extent; the constants differ but little, and are nearly the same for the bromo- and fluo- compounds. It would be of interest to determine whether in the ortho- position also fluorine acts as strongly as chlorine, but o-fluobenzoic acid has not yet been examined; m-cyanobenzoic acid. This completely corresponds to the fact that cyanacetic acid is much stronger than chloracetic acid.

From measurements of the nitrobenzoic acids, the group NO₂ appears to be the most effective negative substituent. The ortho-compound exhibits a 103-fold increase of the constant, the meta-compound an increase equal to 5-8-fold, and the para-compound a 6-7-fold increase. With regard to the influence of position, the numbers agree with those found for the ohloro- and bromo-compounds, in so far as the ortho-position is again that of greatest influence; but, on the other hand, the influence of the nitro-group makes itself more felt from the para-position than from the meta-position, in opposition to the relations found in the case of chlorine.

Bromonitrobenzoic acid contains the subtine constant is made up of that of benzoic acid, and of the factor of the o-nitro group 103, and that of the m-bromine 2·3, and is therefore calculated to be 1·38, which agrees well with 1·4, the value found by experiment. In this case, therefore, the mutual influence of the simultaneously present substituents is practically zero.

The constants of o- and p- amidobenzoic acid show that the amido- group considerably reduces the strength of the acid. But the values quoted can only be looked upon as approximations, since peculiarities appear in the determinations which are not yet elucidated.

But the numbers become regular when the basic properties of the amido- residue are compensated by the introduction of acetyl. Of the three acetamidobenzoic acids the ortho- compound is the strongest, it surpasses benzoic acid by four times its value. The meta-compound is only 14 times as strong as benzoic acid, and in the para-position the atomic group NHCOCH, acts similarly to hydroxyl—that is, it exerts a weakening effect—the constant is only 0-86 of that of benzoic acid. The acetyl-oxybenzoic acids behave quite similarly; their factors re-

latively to benzoic acid are 5.5, 1.6 and 0.76. On comparing with these and the former numbers the factors of the oxybenzoic acids-namely, 17, 1.4, and 0.5-it follows that the substituent which in the ortho-position acts most strongly also exerts the greatest weakening influence in

the para- position.

But this relation again is not universal. Replacement of hydroxylic hydrogen by methyl in salicylic acid produces a quite extraordinary weakening of the acid; instead of 17 times, the constant is only 1.4 times, as great as that of benzoic acid. In the para-position, however, the same change produces scarcely any effect; the constants of p-oxybenzoic acid and of p-methoxy-benzoic acid or anisic acid are nearly the same, and the decreasing effect of the group OCH, is much greater in the para- than in the ortho- position.

It is further remarkable that acetosalicylic acid is weaker than salicylic acid, in spite of acetyl being a negative radicle. It may be that the cause of this curious behaviour is to be found in a change of linkage similar to that mentioned

ahova.

Cuminic acid C.H. (C.H.,)CO.H .	0.0050

A comparison of the constant of benzoic acid with those of the toluic acids shows that a doubling of value has occurred by the introduction of methyl into the ortho-position, but that, as usual, the methyl group in the meta or paraposition has a slightly weakening effect. The isomeric phenylacetic acid also has a very similar constant. This constant is 3.1 times greater than that of acetic acid—an indication that phenyl is a negative radicle - but it does not attain to the value of benzoic acid.

The constants for the two phenylpropionic acids show that, as in the case of a- and \$\beta\$- oxypropionic acids, the acid in which the phenyl is at a greater distance from the carboxyl is the weaker. The other relations to be expected are also found; between propionic acid and a-phenylpropionic acid there is the same ratio of the constants, 3.1, as between acetic and phenylacutic

Cuminic acid differs from p-toluic acid only in that it contains isopropyl instead of methyl. To this small difference in constitution correanonds as small a difference in the constants

sponds as small a difference in the con	ave	P11 60.

Hydroparacoumaric		
acid CH ₂ (C ₂ H ₄ .OH)CH ₂ .CO ₂ H.	•	0.0017

Mandelic soid is phenylated oxyscetic soid; the ratio of its constant to that of glycollic acid is 2.7, while that between acetic acid and phenylacetic acid is 8.1; both values approxi-

mate closely to each other.

On introducing into the phenyl of phenoxyacetic acid a nitro-group in the ortho-position, the constant rises to double its value. The introduction of NO, in the ortho-position into benzoic acid raises the constant to 103 times its former value. This enormous difference exemplifies most prominently the influence exerted by the varying distance of the substituent from the carboxyl. The same thing is made evident by the constant of p-nitrophenylglycollic acid, which is scarcely different from that of the ortho- compound; the change from the ortho- to paraposition, which is generally so influential, is of scarcely any account at this distance from the carboxyl.

Tropic acid is a phenyl-B-oxypropionic acid. It is 2.5 times stronger than exprepionic acid. For the influence of phenyl in the a- position we have before found the factors 27 and 3.1.

Phloretic acid is phenylpropionic acid whose phenyl contains a hydroxyl in the para- position; its constant is half as great as that of phenyl-propionic acid; hence the para- hydroxyl here exerts its characteristic weakening effect.

In the same way hydroparacoumaric is hydrocinnamic acid which contains a parahydroxyl in the phenyl. This also has a decreasing action on the constant, but owing to the greater distance of the phenyl this effect is

not so great as in the preceding case.

Unsaturated acids. The affinity co-efficients of these substances present a special interest owing to their isomeric relations, which cannot be represented by the ordinary chemical formulæ. Following up an idea of van't Hoff, an explanation of these phenomena has lately been given by Wislicenus (Abh. König. Sáchs. Ges. der Wiss. 1887). In this explanation the cause of the chemical differences is supposed to lie in differences in the relative positions in space of the radicles linked to the carbon. Since the results so far obtained from a consideration of the affinity-constants invariably point to relations in space, it becomes possible to subject this hypothesis to an experimental examination. Acrylic acid CH,:CH.CO,H

Crotonic acid Cli(CII,):CH.CO.H 0.00204 Isocrotonic acid CH(CH3):CH.CO2H . 0.0038 Tiglic acid CH(CH₃):C(CH₃)CO₂H 0.00096 Angelic acid CH(CH₃):C(CH₂)CO₂H 0.0050 a Chlorocrotonic acid 0.0720 CH(CH3):CCl.CO2H.

allo-a-Chlorocrotonic acid CH(CH,):CCl.CO,H. 0.158 8-Chlorocrotonic acid

0.0144 CCl.(CH₃):CH.CO₂H allo-B-Chlorocrotonic acid

CCl.(CH,):CH.CO,H 0.0095 A consideration of these numbers shows that the unsaturated acids have in general greater constants than the saturated ones. We must, therefore, ascribe to hydrogen a strongly basic character. And, further, as in the case of the saturated fatty acids, the constants on the whole decrease as the carbon increases. And, finally, . 0.0017 we see that the isomeric acids for which, according to the views hitherto held, no difference of constitution could be formulated are in fact distinctly different.

Now Wislicenus represents the difference between crotonic acid and isocrotonic acid by the following formulæ:--

Crotonic acid

$$H>C=C< CH_3$$
 $H>C=C< CO_3H$

and

 $H>C=C< CO_3H$

In crotonic acid the methyl group stands nearer to the carboxyl, in isocrotonic acid the hydrogen. Since, in accordance with present experience, a methyl group linked to carbon which is also directly linked to CO,H decreases the constant, a smaller constant must be expected for crotonic acid than for isocrotonic, this difference being more pronounced owing to greater proximity in space. Experiment con-firms this conclusion, and thus proves the appropriateness of Wislicenus' assumption.

It may be asked whether we are not here dealing with one of the cases of which some were mentioned before, in which, as an excep-tional case, the methyl acts by increasing the strength. But this view is excluded, since both acids are weaker than acrylic acid. Methyl has, therefore, in both cases reduced the strength, but to a greater degree in crotonic than in the

iso acid.
Wislicenus assumes similar differences in constitution for angelic and tiglic acids. We get

Hence angelic acid again would have to be stronger than tiglic, as has been verified by experience. But it is remarkable that in this case the difference has been found to be much greater than in the first one. Angelic acid has a greater constant than isocrotonic acid, which contains CH, less than angelic acid, a fact as unusual as that tiglic acid exhibits a smaller constant than the corresponding saturated acid, valeric, which has for constant 0 00161.

In the same way the values found for the a-chlorocrotonic acids agree with experience. The constants are very nearly in the same ratio as that of those of the two crotonic acids themselves, and the rise effected by the chlorine introduced into the a-position is represented by the factors 36 and 44, which, though markedly smaller, are of the same order of magnitude as the factor for monochloracetic acid.

In opposition to the agreement holding hitherto between theory and experiment, in the case of the β-chlorocrotonic acids, the allo- compound proves distinctly weaker than the deriva-tive of crotonic acid. The cause of this discrepancy cannot yet be established. The ratio of the constants for crotonic acid and \$-chlorocrotonic acid is 1:7, which is nearly the same as the corresponding factor for propionic acid and β-iodopropionic acid, viz. 6.6. On the other hand, the ratio for the factors of isocrotonic acid and the allo-B-chloro- derivative is 1:2.6, and is, therefore, much smaller.

Tetrolic acid is formed from both \$-chloroerotonic acids by splitting off hydrochloric acid; the constant is Tetrolic acid CH, C:C.CO.H .

Though hydrochloric said is one of the strongest acids, yet the splitting off of its elements from the \$-chlorocrotonic acids not only has not lowered the constant, but has raised it This result makes evident the considerably. strongly acid nature of carbon and the basic nature of hydrogen; the removal of four hydrogen atoms from butyric acid, whose constant is 0.00149, has produced a rise in the constant of 160 times its value.

Of other unsaturated acids the following have heen measured ---

0.00241

Hydrosorbic acid C₅H₈.CO₂H Sorbic acid C₅H₇.CO₂H Parasorbic acid C₅H₇.CO₂H 0.00173 0.00178 Ethyl-methacrylic acid C,H,.CO,H 0.00111 Atropic acid CH.:C(C,H,)CO,H . Cinnamic acid CH(C,H,):CH.CO,H 0.0143 0.00355 Isocinnamic acid CH(C,H,):CH.CO,H 0.0156 p-Coumaric acid CH(CaH4.OH):CH.CO2H 0.0022o-Coumario acid CH(C,H,OH);CH.CO,H 0.0021 Umbellic acid $CH(C_0H_2(OH)_2):CH.CO_2H$ 0.00188 a-Bromo-cinnamic acid CH(C.H.):CBr.CO.H 1.44 8-Bromo-cinnamic acid CH(C₆H₅):CBr.CO₂H

Phenylpropiolic acid C,H,C:C.CO,H . 0.59 o-Nitro-phenylpropiolic acid C₈H₄NO₂.C:C.CO₂H In accordance with the general rule, hydro-

sorbic acid is stronger than the corresponding saturated compound, which is caproic acid (k = 0.00145), while sorbic acid, which contains 2H less, is not stronger but weaker than hydrosorbic acid. It is, therefore, probable that sorbic acid has not one treble linkage, but two double ones, oreit may have an altogether different constitution, perhaps one with a closed chain arrangement of the carbon atoms.

Sorbic acid is sometimes obtained in the form of an oil which only when treated with acids or alkalis passes into the crystalline acid. Since it did not seem impossible that this was a case of isomerism, such as that of crotonic and isocrotonic acid, the constant of the liquid parasorbic acid was also measured. It proved identical with that of sorbic acid, and hence, with Fittig and Baringer (A. 161, 325 [1871]), these substances must be considered, not as isomeric, but as chemically identical.

The constant of methylethylacrylic acid is remarkably small; it is smaller than that of the saturated fatty acid, and approaches that of tiglic acid. The acids a-phenylacrylic, or atropic, and \$-phenylacrylic or cinnamic, behave as we should expect; the phenyl group causes a much higher value of the constant when it is in the α - than when it is in the β - position. But it is remarkable that cinnamic acid is not only weaker than atropic acid, but even weaker than acrylic acid; in this case, then, the phenyl group lowers the constant.

In the case of cinnamic acid, two 'geometrically isomeric' compounds may be expected, namely-

$$\overset{H}{\underset{C_{\bullet}H_{\bullet}}{\sim}} C = C < \overset{CO_{\bullet}H}{\underset{H}{\sim}} \quad \text{and} \quad \overset{H}{\underset{H}{\sim}} C = C < \overset{CO_{\bullet}H}{\underset{\bullet}{\sim}}$$

Quite recently there has been discovered by Liebermann a second cinnamic acid which must be regarded as geometrically isomeric with the ordinary one; it has a much higher constant than the latter, and hence we may conclude that in the new isocinnamic acid the neg ative phenyl has a closer connexion with the carb oxyl than in the old one, and that the new acid may have the second of the above formulæ.

Similarly, there are known two isomeric bromocinnamic acids, which are produced from cinnamic acid dibromide by splitting off hydrobromic acid, and for which the same kind of isomerism holds. Nor can there be any doubt as to which acid corresponds to each formula, the differences in the constants being very great, and in fact it has been made known quite recently by Erlenmeyer that he has obtained Liebermann's isocinnamic acid from the stronger a-bromocinnamic acid.

The phenylpropiolic acid formed from the acid is stronger than the \$\beta\$- compound, but weaker than the isomeric \$\alpha\$- compound. The constant is also, as was to be expected, greater than that of tetrolic acid. In o-nitro-phenyl-propiolic acid the nitro-group in the orthoposition has again been able to exert but a slightly strengthening action, owing to its being at a great distance from the carboxyl.

On comparing einnamic acid with p-coumaric acid, we find that the hydroxyl introduced into the p-position again lowers the constant. But, strange to say, a similar effect is produced in the derivatives of cinnamic acid by hydroxyl in the ortho-position; o-coumaric acid is also weaker than cinnamic acid. It is in accordance with this that umbellic acid, which contains one hydroxyl in the ortho-position and a second one in the para-position, is weaker than all these acids. It is to be expected that these relations will prove of importance for the complete clucidation of the constitution of these remarkable compounds.

Dibasic acids. The acids of the oxalic series save the following constants:

Oxalie acid (CO,H),	. 10(?)
Malonic acid CH ₂ (CO ₂ H),	. 0.158
Succinic acid C ₂ H ₄ (CO ₂ H),	. 0.0066
Pyro artaric acid C.H.(CO.H).	. 0.0048
Adipio acid C ₄ H ₈ (CO ₂ H),	. 0.0037
l'imelic acid CaHie(CO,H).	• 0.0036
Suberic acid C ₆ H ₁₂ (CO ₂ H) ₂	. 0.0026
Sebacic acid C, H, (CO, H),	. 0.0023
Tallian almost and the control of th	4 (1

It has already been explained that the weaker dibasic acids H.R¹¹ split electrolytically according to the scheme H + HR¹¹, and that therefore constants may be calculated for these acids in a manner analogous to that adopted for the monobasic acids. In the case of oxalic acid, however, this is not possible, since the dissociation has proceeded too far; the constant is only estimated approximately, but beginning from malonic acid, the values of the constants can be very well determined.

We see that at first the constants decrease very rapidly; that of malonic acid is about 60 times smaller than that of oxalic acid. From malonic to succinic acid the step is much smaller, 24:1, and much smaller from the latter to pyrotamaric acid, 14:1, and henceforward

the numbers vary only by small amounts. The influence which one carboxyl group exerts on the hydrogen of the other decreases, therefore, very rapidly in consequence of the interposition of the carbon atoms; sebacic acid does not surpass by more than twice the fatty acids richer in carbon. Of the numerous isomerides with side carbon chains, the following have been measured:

Methylmalonic acid CH(CH₃)CO₂H
Ethylmalonic acid CH(CH₄),CO₂H
0-127
Dimethylmalonic acid C(CH₄),CO₂H
Methylsuccinic acid C₄H₄(CH₄),CO₂H
α-Dimethylsuccinic
acid C₄H₄(CH₄),CO₂H
β-Dimethylsuccinic
acid C₄H₄(CH₂),CO₂H
0-0343
β-Dimethylsuccinic
acid C₄H₄(CH₂),2CO₂H
0-0245

The three first acids appear at once to be derivatives of malonic acid; their constants do not differ much from that of their parent substance, but all are somewhat smaller. Similarly, the constants of the derivatives of succinic acid appreach to the value of the latter, but are all greater. The alcoholic groups have therefore acted in these cases in the ordinary way: an explanation of this has been attempted by Bethmann (Z.P. C. 5, 407).

The amido- group entering into one of the carboxyls of oxalic acid causes a weakening of the acid to one-twelfth its value; the much more weakly basic urea residue produces a much smaller weakening effect, viz. to about half the value. The decrease caused by the residue of aniline is smaller also, to about the eighth part; when chlorine enters into the phenyl of the latter, there again occurs an increase in the acid properties, which increase, however, in consequence of the greater distance, is much smaller than in benzoic acid. But a distinct difference between the ortho- and the para-position still asserts itself. Methyl in the para-position exerts a distinctly weakening effect.

Tartronic acid CH(OH)(CO,H), 0-107
Phenylmalonicacid (C,H,),C:(CO,H), 0-408
Malonanilic acid CH,CO(NHC,H,)CO,H .0-0196

Strange to say, in spite of the hydroxyl, tartronic acid is weaker than malonic acid (k=0.158). The replacement of both hydrogon atoms of malonic acid by benzylic radicles raises the constant. Finally, malonanilic acid is about eight times weaker than the parent substance.

Oxysuccinic, or malic, acid has a constant
six times as great as succinic acid. The factor
is somewhat smaller than for the monobasic
acids, which may be because a negative radicle
carboxyl is already present. The natural opti-
cally active acid has exactly the same constant
as the inactive acid got from monobromsuccinic
acid. The same relation recurs in fartaric acid
and racemic acid. Both the dextrorotatory and
the hove to to to the indeting the indeting the comic

the levorotatory acid, as also the inactive raceinic acid formed by a combination of these two, are all of exactly the same strongth. This result is in accordance with the present views concerning the constitution of these compounds. dextrorotatory and lavorotatory acids contain their constituents in a perfectly symmetrical arrangement, and must, therefore, have equal co-efficients of affinity. It has been assumed that the optically inactive acids produced from the optically rotating ones consist each of two molecules of the active acids. This is probably correct for the solid crystallised substances, but not for solutions; in these, both compounds are present side by side, uncombined, a conclusion which has also been arrived at in another way by Perkin (C. J. 52, 362). The undecomposable inactive mesotartaric acid has, however, another, and that a smaller, constant; theory also ascribes to it a different constitution. In the preceding table are further contained

a number of derivatives of phenylsuccinamic or succinanilic acid. This acid itself is only 3.3 times weaker than succinic acid, while the introduction of the anilline residue into CO, H of malonic acid decreased the strength 8 times; this indicates that the position of the substituent at a greater distance weakens the effect. The almost complete equality of the constants for all substitution products of succinanilic acid is of great interest; the distance of the benzylic residue from the carboxyl is here too great to allow the substituents to exert their effect over it. The usual assumption, that the molecular forces cease to act at even very small distances, is thereby made more definite, in that such distances are already given by the molecular dimensions.

As already found, the introduction of the urea residue produces a smaller decrease than that due to aniline. Smaller still is the effect of the thio-urea residue.

Ov100

Ov250

Ov100

Ov200

Ov200

As we were led to expect, the entry of a carboxyl in the ortho-position produces a somewhat considerable rise in the constant—vis. to twenty times the former value. For the metaposition the factor is only 4.8. p. Phthalic acid is too insoluble to be measured. But assuming that in oxy-p-phthalic acid the hydroxyl acts as strongly as in salicylic acid, the constant of p-phthalic acid would be estimated as 0.014 to 0.015, and it would follow that, in accordance with the usual result, carboxyl in the para-position—i.e. in the distant one—exerts the least action. A weakening effect, such as is exerted by hydroxyl in the para-position, seems to be excluded.

The amide residue in phthalamic acid has lowered the constant to one-eighth its value, but the acid is yet stronger than benzoic acid, and the group CONH, must be looked upon as negative. The urea residue exerts, as it always does, a much less marked weakening effect.

Unsaturated dibasic acids. The dicarboxylic acids $CH_{2n-2}(COOH)_2$ exhibit very similar isomeric relations to those of the compounds of the acrylic acid series. The following were neasured:—

The isomeric compounds are seen to have widely different constants. These results agree very well with the views of van't Hoff and Wislicenus. For fumaric and maleic acids the following formulæ have been adopted:

$$\begin{array}{c} \text{Malcic acid} \\ H > 0 = C < \stackrel{CO_2H}{CO_2H} \\ \end{array} \qquad \begin{array}{c} \text{Fumaric acid} \\ H > C = C < \stackrel{CO_2H}{CO_2H} \\ \end{array}$$

According to this, the two carboxyl groups are much nearer to each other in maleic than in fumaric acid, and the first must be stronger, as is actually the case. Similarly, according to Wislicenus, the formulæ

$$\begin{array}{ccc} \text{Citraconic acid} & & & \text{Mesaconic acid} \\ H > C = C < & \text{CO}_2 H & & & \text{CH}_3 > C = C < & \text{CO}_2 H \\ \text{CH}_3 > C = C < & \text{CO}_2 H & & \text{CO}_3 H \\ \end{array}$$

hold, and for the same reason citraconic acid must be stronger than mesaconic acid, which conclusion again agrees with experiment.

CH,: C-CO,H

Itaconic acid has the formula

H.C-CO.H

and therefore no double linkage between the carbon atoms combined with carboxyl. Accordingly, its constant is much smaller; it is only twice as great as that of succinic acid.

It may be mentioned that acetylene dicarboxylic acid $\overset{C}{C} - CO_x H$ is so strong that a constant cannot be determined for the first stage of dissociation. The acid is but little inferior to sulphuric acid.

The replacement of the group C2H	, ir	benzoi c
acid by sulphur raises the constan	nt	to five
times its value, provided the carboxy		

acid by sulphur raises the constant to five times its value, provided the carboxyl is placed next to the sulphur. In the \$\mathcal{\theta} position the carboxyl is without doubt influenced less, but we have yet no measurement of the constant.

It is remarkable that a similar replacement of C.H. by oxygen, forming pyromucic acid, acts much more strongly than a replacement by sulphur. On account of the magnitude of the constant it is very probable that in pyromucic acid the carboxyl is in a position next to the oxygen.

Differently from sulphur and oxygen, the replacement of C₂H₂ by CNH has a strongly weakening effect on the constant. The values found for the monocarboxylic acids of pyridine correspond fairly with the assumptions which might be made on the basis of the constitutions of these substances; picolinic acid, which contains the carboxyl next to the nitrogen, is by far the weakest; but the β- acid is stronger than the γ- compound, so that in pyridine the β- position proves the place of smallest influence.

The behaviour of the dicarboxylic acids of pyridine is very unexpected. While all monocarboxylic acids of pyridine are weaker than benzoic acid. all dicarboxylic acids are stronger than the strongest dicarboxylic acid of benzene -that is, o-phthalic acid, whose constant is 0.12. A further difference is that the strongest dicarboxylic acids are those which contain carboxyl in the a- position—that is, next to the nitrogen. Then follow the acids which contain carboxyl in the γ - position, and lastly those with carboxyl in the β - position. These relations are the exact reverse of those observed for the monocarboxylic acids; where a decrease of the constant had been observed there, an increase is found here. No plausible hypothesis concerning the cause of these peculiar phenomena has yet been brought forward.

Owing to the entry of hydroxyl in the orthoposition, cinchomeronic acid has had its constant increased to eight times its value. The methyl groups increase the strength of the $\beta\beta$ -dicarboxylic acid, and they do so to a greater extent in the γ -position than in the α -position.

Further, several poly-carboxylic acids of pyridine were examined; the constants cannot, however, be calculated, because the dissociation assumes a somewhat complicated character. But it is evident that the relations found in the case of the dicarboxylic acids concerning the influence of the position of the carboxyl hold good in these cases also. The rules found for detailed discussion.

the dicarboxylic acids were also confirmed in the case of methyl derivatives of the tricarboxylic acids. On the other hand, phenyl on entering into lutidine dicarboxylic acid, whose constant is 0.34, has a weakening effect, the constant for the compound formed being only 0.012. The action here is the reverse of that observed in the case of the fatty acids.

The results obtained from measurements of the amidobenzene sulphonio acids are somewhat remarkable. While benzene sulphonic acid itself is so strong an acid that its dissociation constant cannot be determined, its amido-derivatives can be measured with ease; the amido- group has, therefore, as it usually does, exerted a weakening effect. But in the case of the carboxylic acids the ortho- position was always that of greatest influence; here it appears as the position of least influence. The weakest of the three acids is the meta- compound, then follows the para- compound, and then the ortho- compound, which comes nearest to the parent substance. The assumption is thus suggested that, by the agency of the group SO, the hydrogen is brought to such a distance from the benzene nucleus that it is more influenced by the radicles in the meta- position than by those in the ortho-

position.

These acids exhibit the usual relations to be expected from the nature of the substituents and their position, and thus do not call for any detailed discussion. General considerations. The properties of chemical compounds, which can be expressed numerically, may be divided into three groups—the additive, the cumulative, and the constitutive. The first are of such a nature that in chemical compounds their value is the sum of the corresponding values of the constituents; these values have led to the conception of the atomic theory—i.e. to the assumption that the components continue to exist in the compounds as such.

The cumulative properties exhibit the peculiarity that, independently of the number and nature of the constituents, their numerical value is the same for certain complex systems. These have led to the conception of the molecular theory—i.e. to the assumption that the components of chemical compounds primarily form similar groups or systems, which have an individual existence, and out of which the visible and ponderable substances are built up.

And, finally, there exists a third group of properties, which are neither additive nor cumulative, since even in the case of substances having the same composition they can assume different values. These have led to the assumption that, in addition to the nature and number of the composing atoms, the properties of substances are influenced by still another condition. This condition has, from the time of Berzelius, been considered to lie in the different arrangement of the atoms within the molecule—i.e. in the constitution.

Of all the constitutive properties hitherto known—such as boiling-point, melting-point, colour, crystalline form, &c.—not one affords a clear insight into the determining cause, the chemical constitution. It is possible, when the latter has been found, more or less approximately, by purely chemical methods, to establish empirical relations; but these lie on the surface only, and lack generality. The cause of this is the defective development of our conceptions concerning the kind and the amount of the influence which the arrangement of the elementary atoms in the molecule exerts on the properties mentioned.

I believe I am not deluding myself when I affirm that the affinity constants, which represent a property of eminently constitutive nature. are far superior to all others with respect to their theoretical applicability. The result that one and the same atom exerts quite different effects, ac-cording to the 'position' which it occupies in the molecule, and that these effects are the greater the more close is the relation of the atom to that of the acid hydrogen, leads to the general inforence that these effects are functions of the distance in space of the atoms in question. But thereby, for the first time, is gained a means of taking measurements in space of molecular structures. There is no doubt that long and laborious work is needed before such measurements will lead to results which will give an allsufficient representation of the form of molecules. But it already seems certain that this goal can be reached.

It has been mentioned, to start with, that k, the affinity co-efficient of acids, appears, generally speaking, as a product whose factors are given by the nature and position of the elementary

atoms composing the acid. This follows from the fact that with analogous changes in analogous substances the constants change in the same ratio-i.e. that in consequence of these changes the constants of the original substances must be multiplied by the same factor. But these factors are never exactly the same, just because two analogous changes are never exactly the same. If, for instance, we change acetic acid into glycollic acid, and propionic acid into lactic acid, the two changes are, it is true, very much alike; but in the first case the hydroxyl takes up a position next to two hydrogen atoms. in the second case next to one hydrogen atom and one methyl; the hydroxyl is therefore subject to a different influence, and will in consequence necessarily act differently on the carboxyl. The same holds for all corresponding cases. The approximate character of the general relation follows, therefore, as a necessity; the deviations from the type are caused by the nature of the subject, and themselves afford a means for bringing to light their cause, which is the secondary influence mentioned above. What has been said concerning the constitutive properties generally—that they can never be completely represented by a general scheme, because this is contradictory to their nature holds particularly for the affinity co-efficients. In them the whole variety of nature asserts itself, and within the framework of great and general regularities produces the finest individualisation.

The form of the dissociation-constant as the product of factors $c = c_1.c_2.c_3...$ has a deeper significance, which is recognised on going back to the dissociation-formula itself. This formula is obtained from the mechanical theory of heat in the following form:

$$\log \frac{p}{p_1 p_2} = \frac{\rho}{R\tau} + C$$

where p_i and p_i are the partial pressures of the products of decomposition, p the pressure of the undecomposed substance, p the heat of dissociation, τ the absolute temperature, R the gaseous constant, and C is a value which is a function of the temperature only, and which, therefore, at constant temperature can be looked upon as a constant.

In the case in point $p_1 = p_2$, and since p_1 and p must be put proportional to $\frac{m}{v}$ and $\frac{1-m}{v}$, it

follows that $\frac{p}{p_1^2} = \frac{(1-m)v}{m^2}$ and thence

$$\log \cdot \frac{(1-m)v}{m^2} = \frac{\rho}{R\tau} + C$$

$$\log \frac{m^2}{(1-m)v} = -\frac{\rho}{R\tau} + C^1.$$

Now the affinity co-efficient is $k = \frac{m^2}{(1-m)n}$; and since, on the other hand, quite generally $k = k_1, k_2, k_3, \ldots$ it follows that

$$\log k_1 + \log k_2 + \log k_3 + \dots = -\frac{\rho}{R\pi} + C^1.$$

The constant C' depends only on the unit adopted and on the point chosen as zero; if, therefore, there appears on the left side of the equation a sum of terms represented by log.k, there must correspond to each of these on the right side a term of the form $-\frac{\rho_n}{R\tau}$, so that $\frac{\rho}{R\tau}$ also resolves itself into a sum of corresponding terms $-\frac{1}{R\tau}(\rho_1+\rho_2+\rho_3+\ldots)$ in which one R_n and

one ρ_n always correspond to each other.

This means: The natural logarithm of the dissociation-constant or affinity-constant is (save for a constant) proportional to the heat of dissociation of the acid in splitting into ions. Since the value of the dissociation or affinity-constant is known from experiment to be the sum of a series of terms which depend on the nature and on the position of the constituent atoms, it follows that the electrolytic heat of dissociation also is the sum of a corresponding number of terms each of which is fixed by the nature and position of each individual atom.

Now in this case the heats of dissociation are the exact measures of the quantities of work which are done in the separation of the acid hydrogen atom from the negative ion. This is so because no external work has to be taken into account, and because the condition of the substances dealt with very closely approaches that of ideal gases. Hence the heat of dissociation measures the potential or the force-function of the atomic system at the corresponding point. and we see that this force-function is the sum of the values which, according to their nature and position, the individual atoms contribute to the total value. And thus elements which, like chlorine, sulphur, &c., raise the constant k, cause a decrease of the heat of dissociation, since log.k and p have different signs. The amide group. on the other hand, which decreases the constant, raises the heat of dissociation-i.e. it increases the amount of work necessary for splitting off the acid hydrogen.

It is by these considerations that the long-mooted question concerning the connection between chemical affinity and the thermal values of reactions has been decided in principle. In this result we see the eminently constitutive property of affinity-quantities brought back again to the additive form. This has been effected by introducing the influence of constitution, or of position in space, into the terms themselves. A similar development awaits the theory of all constitutive properties, as, in fact, we are forced to conceive the combined action of different elements as the sum of various effects.

Electrical theory of chemical affinity. Elsewhere (AFFINITY, vol. i. p. 67) the laws of chemical affinity have already been explained. Nothing definite could be stated concerning their cause; but it followed from the close connection which was shown to exist between the co-efficients of chemical reacting power of electrolytes, and the values of the electrical conductivities, that an intimate relation exists between these two properties. The prospect is thus opened of carrying out in an exact form the electro-chemical theory of affinity which was rather conjectured than worked out by Davy and Berzelius.

The new view which affords such a possibility is the common cause underlying electrolytic conduction and chemical reactions as recognised by Arrhenius, viz. the existence of free ions. On making the assumption, which is justified by Vol. 1V.

this concordance, that chemical processes between electrolytes take place only by the agency of the free ions, the laws of chemical affinity, which have been established empirically, can be deduces so as to be in accordance with experiment. To do this we only further need van't Hoff's theory of solutions, and the theory of the laws of dissociation as deduced for gases (v. Dissociation is vol. ii.), which laws, thanks to van't Hoff's theory can also be applied to substances in solution.

The general law of chemical affinity first recognised is that manifestations of this affinity on the part of a definite substance are expressible by a definite co-efficient, dependent on the temperature and dilution, but independent of the nature of the chemical reaction in which the substance participates.

Now, if the reacting power of a substance in solution depends on the number of dissociated ions which are present, it can be seen at once that the above-mentioned law must of necessity hold good. So, for instance, the state of dissociation of an acid determines the velocity with which it must act on methylacetate, acctamide, marble, &c. The nature of the other substance determines a factor only, which in analogous cases is the same.

Hence we must conclude that all acids, for instance, when completely dis-ociated are equally strong. The strong inorganic acids HCl, HBr, HI, HNO₂, HClO, must be classed here, as also the sulpho-acids and similar organic acids. No one of these substances exhibits any of the specific differences discussed in former paragraphs for acids of medium strength. They all exert a nearly equal effect when used in equivalent quantities, and approach the maximum conductivity even at moderate dilutions. At a time when the dissociation theory of electrolytes did not exist, the author of this article vainly tried to obtain from benzene-sulphonic acid, by all the means which make weak acids strongersuch as the introduction of halogens, nitrogroups, &c .- acids stronger than the parent substance, which may itself be ranged side by side with hydrochloric acid. This was not possible; all 'strengtheners' remained in this case ineffective. This remarkable fact shows that it is not its special nature, but its electrical condition, which is determinant for the chemical effect of a substance, especially if that substance be an acid.

The greater the number of the molecules which are split into their positively and negatively charged parts, the stronger is the acid; but any ion, when once present in the separated. electrically charged, condition, is as effective as any other. Here, then, we see that Berzelius' conclusion drawn from false premisses, by means of which he attempted to demonstrate the absurdity of Faraday's lar -that then the chemical affinity between the ions of all electrolytes would have to be the same-is perfectly correct. The affinity of the most diverse ions is really the same, because it does not depend on their nature but on their electrical charge, and this, according to Faraday's law, is everywhere the same. What does depend on the nature of the ions is the degree to which they dissociate, and herein alone lies the cause of the differences ₽

In the arguments used so far, it has been assumed that the state of dissociation of the reacting substances is determined by the volume and the temperature, and that the presence of other substances does not alter the state of the one considered. This case, however, only occurs when there are present either one dissociated substance and nothing but non-electrolytes besides, or when all the dissociated substances present are for all practical purposes completely split up. But as soon as several partly dissociated substances are present, the relations become much more complicated.

It is known from the theory of dissociation that when two gaseous substances are present, and the quantities of these substances vary, the product of their active quantities, or of their concentrations, must be constant, constant temperature being presupposed. If, for instance, a given space is filled with the gaseous products of decomposition of ammonium hydrosulphide, the addition of sulphuretted hydrogen will cause a decrease in the quantity of hydrosulphide dissociated, because on increasing the one factor the other must decrease in the same ratio. The same must evidently hold for electrolytes; on adding to a solution which contains the ions A + B an excess of ions A, the quantity of ions B must decrease until the product of the two quantities has again become equal to its original value. Now, it is not very well possible to add ions A only, but an electrolyte can be added which is dissociated, and which contains the ions A + B'; if B' is different from B, the two do not influence each other.

We may now ask how two solutions must be constituted in order that their state of dissociation shall not vary when the solutions are mixed. We have the solutions of the electrolytes A + B and A + B', which contain a common ion A; let their volumes be v and v'. Then, in accordance with the general law of the equilibrium of dissociation, the following equations will hold:

$$\frac{1-\xi}{v} = k\frac{\xi}{v} \cdot \frac{\xi}{v}$$
$$\frac{1-\xi'}{v'} = k'\frac{\xi'}{v'} \cdot \frac{\xi'}{v'}$$

in which the quantities of the electrolytes originally present are put as equal to 1, and the dissociated portions equal to ξ and ξ' respectively. On mixing the solutions, the volume becomes v+v', the dissociation ratios ξ and ξ' remaining unchanged, as supposed. The quantities of the undissociated portions are $1-\xi$ and $1-\xi'$, but the products $\xi.\xi$ and $\xi'.\xi'$ change into $\xi(\xi+\xi')$ and $\xi'(\xi'+\xi)$, since the ion A common to both substances participates in the equilibrium condition of both. We have, therefore,

$$\frac{1-\xi}{v+v'} = k, \quad \frac{\xi}{v+v'}, \quad \frac{\xi+\xi'}{v+v'}$$

$$\frac{1-\xi'}{v+v'} = k', \quad \frac{\xi'}{v+v'}, \quad \frac{\xi+\xi'}{v+v'}$$

On dividing each of these equations into each of the corresponding equations given above, it follows that $\frac{\xi}{\xi'} = \frac{v}{v'}$. Therefore, in order that the state of dissociation should not alter on mixing solutions of two electrolytes which have one ion

in common (for instance, two acids), the portions dissociated must be in the ratio of the volumes.

Writing the equation in the form $\frac{\xi}{v} = \frac{\xi'}{v'}$, the

law can also be expressed in this form; when the concentration of the common ion is the same in both solutions, these do not influence each other.

Arrhenius, to whom we owe these considerations, calls solutions which do not influence each
other in the sense just mentioned isohydric
solutions. Since, in accordance with the above
formula, it is only necessary for this that the
concentration of the common ion in the two
solutions should be the same, the ratio of the
quantities of the two solutions does not enter
into consideration; isohydric solutions can be
mixed in all proportions without mutually
changing their condition.

If, however, two non-isohydric solutions which contain a common ion are mixed, the process can be represented by saying that the one solution withdraws water from the other until both have become isohydric; then they leave each other uninfluenced. This withdrawal of water occurs in the following manner. First. the total concentration of the solution which loses water increases, and thereby the concentration of the ions increases also. But, owing to this, the state of dissociation changes directly, since, in consequence of the smaller volume, the dissociation decreases, and, therefore, the concentration of the ions increases more slowly than the total concentration. Conversely, the concentration becomes less in the portion which takes up water; but, owing to the increase in dissociation, it does so to a smaller degree than corresponds to the volume change.

Since the relation between the volume and the state of dissociation is known for binary electrolytes (p. 194), a formula can easily be deduced which allows us to calculate the characteristic quantities for a mixture of several electrolytes. But it is generally simpler to proceed by way of successive approximation.

Two solutions which are isohydric with a third must be isohydric with each other; because, in order to be isohydric with the third, there must be in both the same concentration of the common ion as is in the third solution.

These laws were all established empirically by Arrhenius (W. 30, 51), and it was only lately that he deduced them theoretically from his theory of dissociation (Z. P. C. 2, 284 [1888]). The examination of these relations is best conducted by making measurements of electrical conductivities. Since the conductivity of a compound in solution is proportional to the number of free ions, it can easily be recognised whether two substances with a common ion-two acids. for instance -- are isohydric; if the conductivity of the mixture is equal to the sum of the conductivities of the components, the solutions are isohydric; if this is not the case, the two numbers differ from each other more or less. To quote an example: with a phosphoric acid solution, of specific conductivity l=225.6, was mixed an equal volume of hydrochloric acid solution 1-225.9; the mixture gave 21-4690, while the sum of the two values is 4515; the observed conducivity was too great by 17.5. Further, the same shosphoric acid solution mixed with an equal rolume of a more dilute hydrochloric acid, =1851, gave for the conductivity of the mix-ure 2l = 4074; this is smaller by 3.3 than the sum 410.7. Finally, hydrochloric acid of l = 168.8gave for the mixture 2l = 394.4, the sum being 194.4; both solutions were isohydric. By such experiments as this Arrhenius arrived at the aws stated above.

It need scarcely be mentioned that any other property of solutions which depends on the molecular condition of the dissolved substance sould likewise have been used for determining the relations of isohydricity. The best of these properties would be measurements of the velocities of reaction for instance, those of the inversion of sugar - these being proportional to the state of dissociation; but the freezingpoints, vapour pressures, &c., could also have been used.

So far the only case considered has been that in which the mixed electrolytes contain a common ion. If this is not the case, new phenomena appear, which we will now consider in greater detail. It has already been pointed out that the theory of free ions leads to a view of the processes of the formation and mutual decomposition of salts which is very different from that generally accepted. It has been shown that, neglecting the small undissociated portions, the process of neutralisation between the strong acids and bases consists exclusively in the formation of water from the ions H and OH. The cause why these ions coalesce to form undissociated water lies in the fact that water is an extremely stable compound, which, under ordinary circumstances, is only very slightly split into ions. If, therefore, such ions anywhere appear simultaneously, they combine directly to form undissociated water.

The phenomena take a quite similar course when a strong acid-hydrochloric, for instanceacts on the salt of a weak acid-sodium acetate. for instance. The former solution is almost exclusively composed of ions II and Cl, the latter of ions Na and CH, CO, Since the sodium chloride also is almost completely dissociated when in dilute solution, the ions Na and Cl are already present in the same condition as in sodium chloride solution, and there exists no tendency to the formation of this compound. But, in addition, there are present the ions H and CH, CO, and these cannot exist side by side without for the most part combining. Hence a corresponding quantity of undissociated acetic acid will be formed, as is actually shown by experiment. But while formerly this fact was ascribed to a specially great affinity between the chlorine and the sodium, and the acetic acid was allowed to play a passive part, being supposed to be 'expelled' by the hydrochloric acid, we now see that the entire cause of the process lies in the action of the acetic acid. Owing to the great affinity of its ions, it is formed whenever its ions meet, while the components of the 'strong' reagents, chlorine and sodium, remain perfectly indifferent in the process. •

The conditions under which chemical equilibrium is established between four substances.

formed by a combination in pairs of two positive and two negative electrolytes, must now be established in a general manner. We assume we have produced four solutions of the substances A,B, A,B, A,B, and A,B, so that those solutions which contain a common ion are isohydric. When this is the case we can, it is true, mix the isolydric solutions in all proportions; but if we mix all four solutions the simple law stated above evidently no more holds, and we must ask in what proportion the mixture must be made in order that no change in the state of dissociation should occur. Let a, b, c, and d be the relative volumes of the four solutions in which this occurs, and let α , β , γ , and δ be the undissociated quantities of the four substances. We can represent the dissociated quantities by ha, hb, hc, and hd, since, in consequence of the assumption made, there must in all cases be equal concentration of the ions. The equations of dissociation of the solutions thus become

$$\frac{a}{a} = k_1 \binom{ha}{a}^2 \qquad \qquad \frac{\beta}{b} = k_2 \binom{hb}{b}^2$$

$$\frac{\gamma}{c} = k_3 \binom{hc}{c}^2 \qquad \qquad \frac{\delta}{d} = k_4 \binom{hd}{d}^3$$

or, $a = k_1 h^2 a$, $\beta = k_2 h^2 b$, $\gamma = k_3 h^2 c$, $\delta = k_4 h^2 d$.

If we suppose the four volumes to be mixed. new equations will make their appearance which

have the form $\frac{a}{a+b+c+d} = k \frac{h(a+b)(a+c)}{(a+b+c+d)^2} &c.$, and which can be brought to the form

$$\mathbf{c} = \frac{k_1 h^2 (a^2 + ab + ac + bc)}{a + b + c + d},$$

$$\mathbf{\beta} = \frac{k_2 h^2 (b^2 + ab + bd + ad)}{a + b + c + d}, &c.$$

The quantities α , β , γ , and δ are to remain unchanged, according to the assumption. Now, by dividing the corresponding equations by each other, the same equation follows from each pair ad = bc,

i.e. the volumes a, b, c, d of the four solutions must be such that the products of the volumes of such pairs of solutions as contain no common ion must be equal to each other.

Now, the volumes a, b, c, and d are proportional to the active or dissociated portions of the four substances present. Calling the total quantities of the latter, p, p1, q, and q1, the values a, b, c, and d are proportional to $m_1 p$, $m_2 p_1$, $m_3 q$, and $m_1 q_1$, and hence we get from ad = bc the equilibrium formula

 $m_1 p \cdot m_1 q = m_1 p_1 \cdot m_4 q_1$ This equation represents not only Guldberg and Waage's formula for chemical equilibrium, but it also contains the extension, made by Ostwald, that every co-efficient of the Guldberg and Waage equation, $k_1pq = k_2p_1q_1$, is made up of two factors each of which depends only on the nature of the ions.

But the equation goes still further than this extension. In the theory of affinity the co-efficients m1, m2, &c. have been considered as constant to a first approximation. But from what has been said it follows that they are not con-stant; they depend on the state of dissociation of the four substances, and are rather com-plicated functions of the dissociation-constants, of the quantities, and of the total volume. The

various deviations from the simple laws which were brought to light by experiment find here their appropriate explanation. Thus it follows that in the case of slightly dissociated acids the degree of dissociation must be considerably lowered by the presence of the normal salts of these acids, which salts are themselves considerably dissociated. The corresponding fact, that such mixtures act much less strongly than the quantity of free acid present in them would do, was known long before theory explained it.

Arrhenius has subjected his investigations on the saponification of ethyl acetate by means of ammonia in the presence of different salts (Z. P. C. 1, 110) to an examination from the standpoint of these newly-established ideas (ib. 2, 289), and has everywhere found them to be in complete agreement with experiment. He has also re-examined a great number of older investigations on conditions of chemical equili-brium in the light of his theory (ib. 5, 1), and here also the discrepancies found when considered from the point of view of the older theory have for the most part disappeared (v. also Z. P. C. 9, 487).

Electromotive forces. Contact theory or

The laws of electromotive force, or of differences in potential produced on the contact of different substances, are not nearly so well known as those of electrical conductivity. It is true the knowledge of the phenomenon itself is as old as that of galvanic electricity, since Volta had already carried out the first approximate measurement of it, but up to the present day no agreement has been arrived at between the different investigators concerning even the chief phenomena.

Volta screwed a disc of zinc coated with isolating varnish on to his straw-electrometer; on the top of this he placed a similar disc of copper, connected the two discs metallically, and after the connection had been broken he took off the copper disc by means of an insulating handle. The electrometer then proved to be charged; examination showed that the straws were charged with positive electricity.

This phenomenon indicates that the substances used-that is zinc, copper, and the isolating coating-charge each other electrically on contact. Volta assumed that, of the three contacts, only the one between copper and zinc was electromotively active; the contact between the metals and the isolating layer of resin was regarded by him as indifferent. Though neither then, nor up to the present day, has a proof of this assumption been brought forward, it has yet met with fairly universal acceptance, and it often passes as a fact not to be doubted.

On the further assumption, which certainly is incorrect, that liquids also-such as water or salt solutions - show no differences of potential with the metals, Volta constructed his electric pile by superposing alternately two metals and a moist card disc. By this he expected an intensification of the electrical effects, since the electricity of the metal lying underneath was to communicate itself through the moist discs to the one lying above, without any change, and so

¹ A complete discussion of this question by O. Lodge is to be found in P. M. [5] 18,

the effects of the individual pairs of metals were to be added together. Volta did, in fact, obtain the expected intensification- a proof that great discoveries may be made on the basis of quite

false hypotheses.

Fabbroni first refused to accept the assumption that the tension of the voltaic pile has its seat only at the point of contact of the metals, and numerous other investigators have taken the same line. Faraday especially, whose work in electrochemistry ranks with the most important done in this subject, was an opponent of Volta's views. He attributed the production of the electric current solely to the chemical processes present, and transferred the cause of the production of electricity to the places at which these processes occur-i.e. the point of contact between the metals and the electrolytes.

The contention thus aroused between the contact theory and the chemical theory of the galvanic cell has lasted to the present day, and even now it is not completely decided. But most of the discussions raised have certainly originated in the insufficient lucidity with which the questions have been stated.

In so far as a galvanic current can be produced only by using electrical energy, it can be maintained, to begin with, that in order to cause a galvanic current there must be present a corresponding source of energy. If other kinds of energy are excluded, as is the case in an ordinary galvanic cell, it can further be said that chemical energy changes into electrical energy, and that, therefore, a theory of the electric currents produced by the voltaic cell must in any case be a chemical one.

But to an electric current there appertain two factors: a quantity of electricity, and a difference of potential. The first is given by the law of Faraday. Since in electrolytes the motion of electricity takes place only simultaneously with the motion of the ions, equivalent quantities of the different ions carrying equal quantities of electricity, a current in a galvanic cell can again not be produced without a corresponding chemical process. From this point of view, also, the theory must be a chemical one. As regards the other factor of the current energy-i.e. the difference of potential-an unequivocal decision, as in the preceding cases, can certainly not be pronounced easily. The experiments on this subject, taken alone, have proved that all substances. when separated from each other after close contact, show themselves to be electrically charged. The smallest differences suffice for this. It has been long known, for instance, that black and white silk stockings which have been pulled over each other are electrically charged after separation. Even in such homogeneous materials as crystals of mica or calcite, the two parts obtained by cleavage of the layers are found to be in different electrical conditions at the original point of contact.

It is imperative, therefore, to accede to the proposition of the 'contact theory,' in so far as to admit that a process occurs at the surface of contact when two surfaces touch, in consequence of which the surfaces are at different potentials after separation. We do not know what the nature of this process is. Helmholts supposes the different substances to possess a different

attraction for electricity, in consequence of which there is brought about a separation of the electricity at the planes of contact; then when the bodies are separated they appear electrically charged. A difficulty with respect to this theory is found in the electrical phenomena attending the cleavage of crystals, where a difference in attraction seems excluded.

In order that the equilibrium of electricity may be changed when two bodies charge themselves oppositely on contact, the expenditure of a certain quantity of energy is required. The source of this energy has to be sought in the change which the surfaces of the bodies undergo

owing to their mutual contact.

In order that this difference of potential may cause an electric current, two things are needed. Firstly, the bodies touching must be conductors, as otherwise the electricity cannot move: and secondly, a cause must be present which will maintain unchanged the condition of the surfaces in contact, in consequence of which condition the arrangement of the electricity is changed; otherwise a charging motion of the electricity could take place once only, but not a continuous current. The current can be produced by mechanical action, and then the phenomena of frictional electricity appear, or the renewal of the surfaces occurs by chemical action, and we deal with galvanic cells.

When considered from this point of view also, the chemical processes appear as the causes of galvanic currents, and a final theory of these currents will doubtless be much more a 'chemi-

cal 'than a 'contact' theory.

Galvanic cells. The simplest conditions for examining the relations between chemical and electrical energy are found in the so-called constant galvanic cells, of which the Daniell cell is a type. This cell consists of a copper plate in a solution of copper sulphate, and a zinc plate in a solution of zinc sulphate; both solutions are in contact with each other. Such a galvanic cell has an electromotive force of about 1.09 volts, which does not change appreciably when the metals are connected by a conductor, and the galvanic current is thus allowed to pass for a longer or a shorter time.

The chemical process in such an element is also of the simplest kind: zinc dissolves to zinc sulphate, while copper is separated from the copper sulphate. Hence the same process takes place as when a piece of zinc is brought into

a copper sulphate solution.

The chemical energy which is available in this process can easily be measured by experiment; it proves to be 50,100 cal. for the reaction

 $Zn + CuSO_1Aq = Cu + ZnSO_1Aq.$

Now, since (p. 180) the unit of electrical energy, volt × coulomb, is equal to 0.2356 cal., this quantity of heat corresponds to 212,600 electrical units.

Now, of the two factors making up the electrical energy of the voltaic cell, one is given by Faraday's law. One gram-equivalent of a metal carries (p. 180) 96,540 coulombs. Since copper and zinc are divalent, the above equation refers to 2 gram-equivalents; when, therefore, 65 g. of sinc dissolve in the Daniell cell, 193,080 coul. are transferred. Dividing this value into the a reversible cycle taking place in the temperature-

| number 212,600 (volt × coulomb), we get 1.10 volts for the electromotive force of the Daniell element, a number which agrees well with the observed value.

This calculation was first carried out by W. Thomson with the help of numbers due to Joule. From the agreement between observation and calculation, the inference was drawn that the assumption made in this case-namely, that the chemical energy transforms itself completely into electrical energy—was universally correct. From this was deduced the possibility of calculating, on the basis of thermochemical data, the electromotive force of all constant elements, and further, the electromotive force of all elements in which the chemical process is known. It was only necessary to multiply the heat of the reaction referred to one equivalent (not molecular

weight) by $\frac{0.2356}{96540} = 0.00000214$. It would also

follow that the electromotive force of all cells would be proportional to the heat of the chemical reaction.

This theory could not, however, be maintained. On the one hand, theoretical doubts were raised, and that specially by Braun (W. 5. 188), against the premisses that the chemical energy of the galvanic cell was always completely transformed into electrical energy; and, on the other hand, experience proved that as a rule the assumed proportionality between heat of reaction and electromotive force did not exist. Raoult (A. Ch. [4] 4, 392) discovered a number of cells, some of which produced less, and some produced more, energy than corresponded to the heat of reaction of their chemical changes; and at a later time it was provedchiefly by F. Braun and Alder Wright (P. M. [5] 19, 1), by means of direct measurement -that only in rare cases do the chemical and electrical energy exactly correspond to each other.

The simple theory must, therefore, be abandoned, and without assuming that the chemical energy is wholly transformed into electrical energy, we must seek to discover a relation between the two. Such a formula has been found by W. Gibbs and H. von Helmholtz (B. B. 1882). The following statement is a simple way of deducing this equation. Let there be given a galvanic cell whose heat of reaction calculated for one equivalent is W. Let its electromotive force at the absolute temperature τ be On raising the temperature by dr the

electromotive force is changed by de.

Now let us carry out the following cycle. The cell is heated from τ to $\tau + d\tau$. Then let the quantity of electricity q, by means of which one equivalent of the reacting substance undergoes chemical decomposition, pass through the cell, the electromotive force remaining + + de, and the temperature being kept constant. Now let the temperature be brought to \u03c4 and, the electromotive force being e, and the temperature being constant, let the same quantity of electricity q be passed through the element in the opposite direction. Thereby the element returns exactly to its initial condition.

According to the mechanical theory of heat, the portion of heat transformable into work, in interval $d\tau$, is $\frac{d\tau}{\tau}$ of the total quantity of heat

produced. Now, the work is given by $qd\epsilon$, and the total heat which has been communicated to and taken from the cell is $\epsilon q - W$. If an electric current alone were produced, the quantity of heat would be ϵq . But since a chemical process also takes place, which yields a portion of the heat—namely, the heat of reaction, W—it is only necessary to communicate the difference $\epsilon q - W$.

We have then the equation -

$$\frac{d\tau}{\tau} = \frac{q d\epsilon}{\epsilon q - W}$$

$$\epsilon = \frac{W}{q} + \frac{1}{\tau} \cdot \frac{d\epsilon}{d\tau}$$

The former equation was $\epsilon = \frac{W}{q}$; we see, therefore, that a correcting term must be added, and that this term is dependent on $\frac{d\epsilon}{d\tau}$, that is, on the change of electromotive force with change of temperature. In the case that $\frac{d\epsilon}{d\tau} = 0$, the new equation is the same as the old one; in the

now equation is the same as the old one; in the Daniell cell the temperature co-efficient is, in fact, nearly equal to zero, and thus it is explained that in this case the chemical energy is equal to the electrical energy.

The equation has been examined in many ways. At first it gave only partially correct results, and in some cases observation and calculation differed from each other. The differences occurred, however, only in cells which contained mercury compounds, and the cause was the use of a wrong number for the heats of formation of these compounds. When this error was corrected by Nernst (Z. P. C. 23) the discrepancies disappeared; and a very careful investigation by H. Jahu (W. 34, 755), in which the thermal and electrical quantities were measured simultaneously, has fully confirmed the correctness of the Gibbs-Helmholtz formula.

The formula has been deduced primarily for constant galvanic cells, and when deducing it the conditions assumed have been expressed: the chemical process resulting from the passage of the quantity of electricity q (which, however, can be as small as we will) must be reversible, by allowing the same quantity of electricity q to pass through the element in the opposite direction. In order that a galvanic cell should fulfil this condition, it is generally requisite that each metal should be surrounded by its corresponding salt. Therefore, when the salt is soluble, the metal must stand in a solution of the salt. In the case of insoluble salts it generally suffices to cover the metallic surface with the solid salt; in this case, either the salt of another metal with the same acid (which salt is not precipitated by the first metal), or the free acid itself, serves as the electrolyte.

The action in a Daniell cell is as follows. Individual atoms of the metal pass from the zinc as positively charged ions into the solution of the sulphate. Since no free electricity can exist within the solution, the copper ions of the copper sulphate must go to the copper plate, where they give up their positive electricity, passing lote ordinary metallic copper. Owing to this

action, a motion of the positive electricity from the zinc to the copper takes place in the solution; on connecting both metals by a wire the current passes continually through it, corresponding quantities of zinc and copper being dissolved, and precipitated, respectively. If the cell is not closed, the zinc becomes charged negatively, owing to the exit of positive ions, and the copper positively, owing to their entrance; and this goes on until the attraction of the zinc for the positive ions, and their repulsion by the copper, is so great that neither can zinc pass into solution nor can copper separate out. The capacity of the ions being enormous, this is brought about by even extremely small numbers of them.

Nernst, who has studied these changes in detail (Z. P. C. 4, 129), assigns to the metals which are in contact with electrolytes definite solution pressures, just as volatile liquids or solids have definite vapour pressures. This pressure is the cause of zinc tending to pass into solution. The solution pressure of copper is very much smaller than that of zinc. Hence when the Daniell cell is newly set up, both metals will at first send positive ions into the solution. But, since no free electricity can exist in the interior of the solution, that metal which has the greater pressure will maintain the preponderance; its ions will pass into solution, and, in order that no free electricity may accumulate in the liquid, an equal number of copper ions must leave the solution, and be precipitated in the metallic state.

Similar arguments hold for all reversible elements. By their help, and with the help of the theories of electrolytic solutions expounded above, a great number of special cases referring to galvanic cells can be deduced theoretically. The results thus obtained have, on the whole, been confirmed by experiment; but details cannot be entered into here.

Besides the constant galvanic cells of the type just described, which are reversible, there still exists a great number of cells which, though practically constant, are not reversible. The constancy of these cells rests on the fact that the nature of the surfaces in contact is not altered by the chemical processes. When metal dissolves at the surface of the zine, and when metal deposits at the surface of the copper, the nature of the bounding surfaces is not thereby influenced; this cell is also reversible, because on sending a current through in the opposite direction zine is precipitated and copper dissolved, but the surface again undergoes no alteration.

Cells of the type of that of Grove, which consists of zinc in sulphuric acid and platinum in nitric acid, are also constant. On working this cell, zinc dissolves, expelling the hydrogen ions from the sulphuric acid; these hydrogen ions go to the nitric acid, whose own hydrogen ions go to the platinum; at the moment when they give up their positive electricity there, and pass into ordinary hydrogen (which, however, is in the nascent state), they are oxidised by the nitric acid to water, and the platinum surface remains unaltered. But such elements are not reversible. When an opposite current is passed through the cell, since the platinum ions cannot pass into solution, the ions NO₂ of the nitris

seid separate out at the platinum, while hydrogen appears at the zine; both these actions change the condition of the bounding surfaces, and thereby simultaneously change the electromotive force also.

Finally, there still remains the large group of the non-constant cells. These are distinguished by the fact that even when the current passes through them in the direct way, the ions separated out produce an alteration in the bounding surfaces, or in one of them at least. To these belongs Volta's cell, which consists of zinc and copper in salt water, and all the other similar combinations. A type still in use is Smee's cell, which consists of zinc and platinum in dilute sulphuric acid. On closing the circuit, zinc ions enter into the solution, expelling the hydrogen, which gives up its electricity at the platinum, whereby it first combines with or dissolves in the metal, and when that is saturated escapes in the gaseous form. In consequence of this, the surface of contact between the acid and the platinum is altered, and the electromotive force also changes, until saturation with hydrogen has taken place; after this point has been reached the electromotive force of Smee's cell remains practically constant. If the cell is left with the circuit open, the hydrogen gradually disappears, partly through diffusion into the air, partly through combination with the free oxygen of the air, induced by the catalytic action of the platinum. Thus, the cell again gradually resumes its original electromotive force. Such cells are, therefore, quite workable in cases where only small quantities of electricity are required at long intervals.

The seat of the electromotive forces. Volta found that no galvanie pile, giving a current, could be produced from metals only. When considered from the point of view of the principles of energy, such behaviour follows necessarily, because, no continuous source of energy being present in a circuit of metals alone, no current can be produced.

The cause of this may be of a two-fold Either there exist no differences of potential between metals, or these follow a definite law, which involves that in a closed circuit these differences just neutralise each other. With Volta, we will assume the latter alternative, of which the former is only a special case. If, then, we have several metals A, B, C. . . and if we call the differences in potential between A and B, A and C, B and C, &c., in succession (a-b), (a-c), (b-c)... the law is that we must always have $(a-b)+(b-c)+(c-d)+\ldots+(y-z)=(a-z)$. The difference of potential of a series of metals depends only on the nature of the first and the last metal, and not on the nature of the intervening metals.

This result necessarily follows if the values $a, b, c \dots$ in the quantities (a-b) &c. are considered as the potentials of the individual metals referred to a zero value which must be fixed arbitrarily. For the zero value of potential we generally use the potential of the earth, or, more correctly speaking, that of a large metallic mass which is in connection with the earth, as are, for instance, iron water-pipes. It can, therefore, be assumed that every metal con-

nected with the 'earth' assumes a definite value of potential which depends only on the nature of the metal. These values of potential are the same for every metal, whether the different metals are in contact with each other

In order to measure these differences of potential, the experiment of Volta mentioned before (p. 212) has been improved upon, in that instead of a dividing layer of resin one of air is used; and, dating from the time that R. Kohlrausch (P. 75, 88) thus carried out the first experiments, a great deal of similar work has been done. But in this case also we are dealing, not with one, but with three separating surfaces-namely, copper-zinc, zinc-air, air-copper, and only when we make the assumption that the differences of potential at the last two surfaces are zero. are we enabled to judge from the measurements of the total difference of potential as to the

difference between the metals.

The legitimacy of this assumption has formed the subject of much discussion. Considering the universality of differences in potential between heterogeneous substances, the absence of a difference between metal and air would be very strange, and we are quite entitled to demand a proof of it from the champions of this view. But, on the contrary, it seems as if the following fact proved the existence of such differences of potential. All the investigators who have undertaken such measurements complain of the extraordinary inconstancy in the differences of potential observed. On placing two freshly-cleaned plates opposite to each other and measuring their difference, one is sure to find different values after a little time. If the surfaces are again cleaned, the original values approximately recur. Therefore, it is not the point of contact of the two metals (besides, this can be made unalterable by soldering), but their surfaces with respect to air, which are the seat of the changes. Let us now assume that at a definite moment the difference of potential of both plates towards air is equal to zero; since another value is observed after some time, the difference of potential of the metals towards air cannot now be zero, i.e. between metals and air there exist differences of potential. How great these are cannot as yet be determined. There is nothing against the assumption that these make up the greatest part of the apparent differences of potential between the metals (measured in air). It is true an attempt has been made to eliminate the influence of the air by making the experiment in vacuo. But since we have learned by observation of the electrical phenomena in vacuum tubes, how difficulthow impossible, even-it is to withdraw from a substance the last remnants of air condensed on it and in it, these experiments cannot be looked upon as affording any conclusive proof.

Other methods for solving the difficulties must be sought. Unfortunately, there does not exist a single process quite free from objection. The following consideration still appears to be

the best :-

When a given quantity of electricity e is brought from a potential A to a higher potential A + a, a quantity of work aq is required. There-

Compare O. Lodge, La.

fore, when we lead a current through two metals which touch in one place, and which there exhibit a difference of potential a, an absorption or a production of energy will occur at the place of contact, according to the direction of the current: and, if there is no other source of energy, this energy-change will be produced from, or will be added to, the heat which is present, as the case may be. In the case of metals such a phenomenon is actually known; it is the effect discovered by Peltier (A. Ch. 56, 371 [1834]). If the strength of the current, and the total heat produced, are measured, the corresponding difference of potential can be calculated. Such experiments have been made by Le Roux, and again quite recently, with great accuracy, by H. Jahn (W. 34, 755), and the results have shown the values to be very small; they are mostly only a few thousandths of a volt.

It is true we must not pass over in silence the following objection made against he validity of this argument. Since we know nothing definite concerning the nature of the electric current. the possibility is not excluded that it may be connected with movements of energy of other kinds. It has been especially assumed as probable by several authors that, simultaneously with the electric current, a heat-current flows through the conductor. If so, the quantity of heat flowing with the unit quantity of electricity might be different in different conductors; and at the point of contact of the metals, in addition to the thermal exchange resulting from the difference of potential, there might occur a further exchange of heat resulting from the difference in the 'thermal capacity of electricity.' Since these two quantities need not have a necessary connection, it would not be permissible to draw any conclusion from the Peltier effect-that is, from the sum of two independent effects -as to the magnitude of the difference of potential.

Without attempting to decide this difficult question here, I should like to draw attention to a circumstance which makes it probable that the second effect, if present at all (which so far has not been proved), must probably be of the same order of magnitude as the difference of potential corresponding to the Peltier effect. According to the second law of the mechanical theory of heat, the carrying of a definite quantity of heat Q from a lower to a higher temperature involves

work which is given by $Q^{\frac{\tau_1 - \tau_2}{\tau_1}}$. If, therefore,

we pass an electric current through a wire whose temperature varies, it follows that, if heat is carried with the current, in places of rising temperature a corresponding quantity of work must be expended, i.e. an opposing electromotive force must there assert itself. Indications of such a force appear to manifest themselves in the so-called Thomson effect (supposing that this effect does not find its explanation in differently heated portions of one metal having differences of potential to each other), but in any case the quantities of work, or the differences of potential, indicated by this phenomenon are extremely small (of the same or of a smaller order of magnitude as those corresponding to the Peltier effects), so that the assumption of an appreciable carrying of heat by means of elec-

tricity (for which, at any rate, we lack the power of forming a conception) seems excluded.

From this it is evident that though nothing quite certain is known concerning the differences of potential between different metals, yet preponderating reasons favour the assumption that such a thing does exist, but that its magnitude does not exceed a few thousandths of a volt, and particularly that it does not attain the order of magnitude of 1 volt. But, varying slightly with the nature of the metals, such a value has been observed by means of the air-condenser method.

As regards differences of potential between various electrolytes, such differences certainly do exist. This can be inferred from the fact that there exist 'liquid chains,' i.e. combinations of different liquids, which produce an electric current. If, for instance, we put into a series of beakers water, concentrated hydrochloric acid, concentrated soda solution, and water, and if we connect these by small syphons or by moist threads, then the two quantities of water at the ends exhibit a difference of potential which may attain to 0.5 volt.

In such liquid chains we have always to deal with three distinct differences of potential at least; designating the three liquids named above by A, B, and C, there exist in the chain the differences of potential (a-b), (b-c), and (c-a), whose sum is observed. There is no combination of the liquids by which we could succeed in obtaining as many independent observations as there are differences of potential, so that it is impossible to determine by measurements on liquid chains only the individual differences of potential.

This determination has, however, been achieved in another way. Since in electrolytes the electricity moves only with the ions, differences in potential between two liquids in contact can only be produced if the different positive and negative ions distribute themselves unequally. A cause for such an inequality lies in the different velocities of migration of the ions (p. 92), and, in an extensive investigation, W. Nernst has shown (Z. P. C. 4, 129) how thereby the actually observed differences of potential can be theoretically calculated in a great number of cases. The fundamental idea of these calculations is the following. When any solution is brought into contact with pure water, forces make themselves apparent at the surface of separation, which forces can be calculated by van't Hoff's theory (pp. 184-5); for 'normal' solutions (which contain one gram molecular weight per litre) they are equal to the pressure of about 22 atmospheres, and they are proportional to the quantity of substance in the solution. Owing to the osmotic pressure, the molecules of the substance are forced into the water. The velocity of their motion is determined by the resistance which they encounter, and this depends on their form as well as on the nature of the solvent.

This statement contains a physical theory of hydro-diffusion (Nernst, Z. P. C. 2, 613), and from it the law of Fick follows directly, that the velocity of diffusion at any point is proportional to the change in concentration at that point. From this we see at once how a separation must occur in the diffusion of dissolved substances,

because those molecules which are endowed with greater mobility or suffer less friction outstrip the slower ones. The same laws hold for each kind of molecules, only the constants are different.

These arguments can only be applied immediately to electrolytes in solution if both ions have equal rates of motion. This condition is very nearly fulfilled in the case of potassium chloride, and this substance conforms, therefore, to the simple law of diffusion.

It is now possible, in the case of electrolytes, to determine the resistances which the ions encounter, as well as to measure the impelling forces. If the ions are moved past each other by electrical forces of separation, they encounter exactly the same resistance, and since in the electrical conductivity we have a measure of the velocity of the corresponding motion of the ions, it is possible, as first shown by F. Kohlrausch (W. 6, 160), to calculate the magnitude of the resistances from a knowledge of the impelling force and of the velocity attained. On introducing this resistance (which, owing to the smallness of the molecules, is enormously great) into the equation for the velocity of diffusion, indicated above, Nernst has found (l.c.) that the velocities of diffusion agree very well with the results of experiment.

In the case of electrolytes whose ions do not migrate with equal velocities the phenomena become much more complicated. stance, we imagine hydrochloric acid, in which the hydrogen ion travels about six times more quickly than the chlorine ion, to be brought into contact with water, the quicker hydrogen atoms will, to start with, pass into water, and the chlorine atoms will remain behind. But since the hydrogen atoms are charged with positive electricity, the water will become positively electrified, while the acid, owing to the preponderance of chlorine atoms, becomes charged negatively. But the further exit of hydrogen atoms is thus rendered more difficult, owing to the electro-static effect, while from a similar cause the chlorine atoms are subject in addition to the osmotic pressure, and also to an electric impelling force, and are thus driven into the water. The consequence is that both ions influence each other's velocity until they again migrate at equal rates.

At the same time, we see that every electrolytic solution whose ions travel with unequal velocities on contact with water—or, speaking more generally, on contact with a solution of different concentration—at once acts as the cause of difference of potential, and also that the more dilute solution will always assume the sign of the ion which has the greater migration velocity. The exact expression which has been deduced by Nernst (i.e. p. 189) is

$$\epsilon_1 - \epsilon_2 = 0.0000860 \quad \tau \quad \frac{u - v}{u + v} \log_1 \frac{p_1}{p_2}$$

Where e_1-e_2 is the difference of potential (in volts) of two solutions in which the osmotion pressures of the (positive as well as negative) ions are p_1 and p_2 ; w is the velocity of the positive, w that of the negative, ion; τ is the absolute temperature, while log. stands for the natural logarithm.

We see that for u=v the electromotive force becomes zero, and it becomes the greater the greater the difference between the migrationvelocities of the two ions. Further, we see that as regards the electromotive force, only the ratio

 $\frac{\mathcal{P}_1}{\mathcal{P}_2}$ of the two pressures, and not their absolute

values, enters into consideration. By increasing the concentration n times in both solutions, the difference of potential does not change. If one of the solutions is pure water, we get $p_2 = 0$, and the electromotive force becomes infinitely great. Since 'pure water' in this sense does not exist, such values cannot come under our observation. But yet we see that liquid chains with 'water' can give very different values according to the degree of purity of this liquid.

The preceding formula is the fundamental expression for all kinds of liquid chains, since in the commination of any solutions the corresponding differences of potential are superposed. It would take us too far afieldeto enter into the different cases; in the memoir of Nernst, a number of cases are discussed theoretically as well as experimentally. But on the whole it may be concluded that the differences in potential apparent on contact of approximately equally concentrated solutions of the most varied kind, vary within fairly small limits, which probably do not surpass 0.01 volt.

Now, since we cannot suppose that differences of potential of the order of magnitude of those observed in galvanic cells exist either between metals alone, or electrolytes alone, we are obliged to regard the surfaces of contact between the metals and the electrolytes as the real seat of the electromotive forces. This result quite corresponds with what was to be expected from the relations between the chemical and electrical energies. This is so because these surfaces of contact are the only seat of the processes by which energy becomes available in the chains, i.e. they are the result of the chemical changes. Since, on the one hand, the cause of the galvanic current of the chains has to be sought in the transformation of chemical into electrical energy, and since, on the other hand, a galvanic current can be produced only when a difference of potential exists, it does not seem very logical to wish to separate in space, and in their nature, the more approximate and the less approximate causes of the same phenomenon, as is done in the assumption that the difference of potential is to be sought at the surface of contact of the metals.

The question now arises again, whether some means does not exist for directly measuring the differences of potential between metals and electrolytes. The answer is that up to the present only one such means is known. A second independent way for arriving at those numbers does not as yet exist, and hence it has hitherto been impossible to put to the proof the results obtained by that method.

The method in question is based on the phenomena exhibited by mercury surfaces when in contact with electrolytes. Lippmann (P. 149, 561; A. Ch. [5] 5,494) has shown that there is a close connection between the condition of the surface of mercury touching an electrolyte and

the electrical state of the system. If, for instance, mercury is covered with dilute sulphuric acid, and the surface of contact between the two is then increased, a galvanic curront is produced, because the mercury becomes less positive on expansion. This can be observed most easily by allowing mercury to drop out of a funnel with a small orifice immersed in dilute sulphuric acid. On connecting the mercury in the funnel and that collected below the sulphuric acid by means of a galvanometer, a current passes from the lower mercury to the higher; in the sulphuric acid the reverse occurs.

This phenomenon is reciprocal. On leading a current through the surface of contact between mercury and sulphuric acid the surface tends to diminish or to increase, according to the direction of the current—i.e. the capillary tension at this point changes. As is always tho case, both phenomena are in such a relation that they oppose each other—i.e. when the surface is made larger the current has the direction such that if it alone were active it would tend to make the surface smaller, and vice versa.

Helmholtz (W. 16, 35 [1882]) has given a theory of these phenomena which is based on the following considerations. When a metal and an electrolyte are in contact, they generally possess a varying difference of potential. Owing to this circumstance, the opposite electricities must accumulate on both sides of the bounding surfaces, since they are prevented from combining by the cause which produces the difference of potential (and which, without making a definite assumption, can be designated as a different attraction of the substances for the electricity). The result is the formation of an 'electric double layer,' which will exhibit a similar arrangement to the charge of a Franklin plate.

But such a double layer will have the property of tending to increase its surface as much as possible, since the similarly electrified particles present at each side repulse each other, and therefore tend to stretch the surface. Hence the development of such a double layer will act in opposition to the surface tension, which seeks to decrease the surface, and the actually observed surface tension is the difference between the real tension and the electric force.

When a surface so constituted is made larger, the electric layers are thereby extended, and their difference of potential decreases. But since, as is known from experience, a constant difference of potential is always formed at the boundary, which difference of potential does not depend on the size of the surface of contact, electricity will flow from the mercury as well as from the electrolyte to replace the loss, and in this way the current is produced.

If, on the other hand, the difference of potential of the electric double layer is changed, the surface tension must change also. It must get smaller when the difference of potential is made larger, and larger when it is made smaller.

By leading electric currents of varying electromotive force through a system consisting of two masses of mercury in sulphuric acid—one of which had a very small, the other a very large, surface of contact with the acid—Lippmann was able to follow the change of surface the sign at the small bounding surface which accom-

panied the change in the difference of potential at that surface. Because, since the change in the difference of potential between a metal and an electrolyte is proportional to the density of the current (current strength divided by the cross-section), the resulting difference of potential practically restricted itself to the small bounding surface, which was surpassed in extension some thousand times by the large one. It was found that when the mercury of the small surface was connected with the positive pole of the external cell, the surface tension decreased. On the other hand, when negative electromotive forces acted, the surface tension increased until the external force was 99 to 10 volt; beyond that it again decreased.

In accordance with Helmholtz's theory, we must infer from this that the difference of potential between mercury and sulphuric acid is of such a kind that the former becomes charged positively—i.e. that the positive electricity of the double layer is on the side of the mercury, and the negative electricity is on the side of the electrolyte. If the difference of po tential is increased by addition of positive electricity to the mercury, the electric repulsion increases, and therefore the surface tension decreases. If, however, negative electricity is added, the charge of the double layer decreases and the surface tension increases. On making the successive additions of negative electricity larger and larger, the difference of potential of the double layer eventually becomes zero; the surface tension has reached its greatest value, and, beyond this, a new double layer of opposite sign is produced. When this state is reached, the surface tension must again decrease.

According to the experiments of Lippmann, the maximum of surface tension is reached when the 'external electromotive force is 0.9 to 1.0 volt. Then no more double layer is present at the small surface of the mercury, and the metal and electrolyte have the same potential. Since this condition is separated from the ordinary one by about 0.9 volt, it follows that the usual difference of potential between dilute subphuric acid and mercury is 0.9 volt.

This result is confirmed by the following experiment of Pellat (C. R. 104, 1099). When the surface of contact between mercury and sulphuric acid is increased, a motion of electricity is produced, owing, as has been mentioned above, to the stretching of the double layer. But this must disappear when, by the use of a difference of potential of about 1.0 volt, the double layer has been made to disappear; and, in fact, under these conditions, Pellat, on changing the surface, could observe no current.

Another confirmation can be obtained in the following manner. When mercury is dropped very quickly out of a fine point into an electrolyte, it must, after a short time, as Helmholtz has shown, assume the potential of the latter (W. 16, 35), because if, for instance, the mercury were at the beginning positive, every falling drop would form a double layer at its surface, which would take positive electricity out of the mercury, and which would make its positive potential smaller and smaller till it became equal to that of the liquid.

But it is to be remembered that the mercury

in contact with sulphuric acid spontaneously becomes positively charged; everything will depend, therefore, on allowing the formation of drops to take place as quickly as possible, in order that the discharge may preponderate over the charge. Experiments by W. Ostwald (Z. P. C. 1, 583 [1887]) have shown that the discharge can be achieved to a great extent, but not completely; there still remain over, even with the best dropping electrodes which have yet been made, differences of some hundredths of a volt. But within these limits the experiment confirms the conclusion which Helmholtz had drawnthe difference of potential between the dropping electrode and the mercury at rest in sulphuric acid amounts in 'normal' sulphuric acid solution to 0.81 volt, while the maximum of surface tension (that is, the true difference of potential) lies at 0.86 volt.

Finally, another inference, which must be drawn from the theory of Helmholtz, has been confirmed by the same author. If the maximum of the surface tension of mercury, as obtainable by means of suitable electromotive forces, actually is the real surface tension of mercury in contact with aqueous liquids, free from auxiliary effects, then it must have the same value whatever be the nature of the electrolyte, while experience shows that the natural surface tension changes considerably with the nature of the electrolyte. This also was confirmed; while the natural surface tension in different solutions varied between 485 and 564. the maximum values were 610 to 611, and were, therefore, practically constant.

All these facts speak for the correctness of Helmholtz's theory of the electric double layers, and leave us, therefore, with the final conclusion that the electromotive force required for producing the maximum of surface tension of mercury in contact with an electrolyte is equal to the ordinary difference of potential at this bounding surface (but with inverted sign). But it must be again emphasised that this is the only group of phenomena from which the values considered can be deduced. An examination of the results by means of another entirely independent method has not yet been feasible.

If, now, the difference of potential between mercury and sulphuric acid is known, the difference of potential between all other metals and sulphuric acid can be measured by experiments which are easily carried out. For this purpose the electromotive force of the combination mercury, sulphuric acid, and metal alone need be measured: this is the sum of the differences of potential of mercury-sulphuric acid and sulphuric acid-metal, and since the first of these is known the other follows by difference. But here it is supposed that no appreciable difference of potential exists between the metals. Again, if the difference of potential between mercury and any other electrolyte is determined, either by the maximum surface tension or by means of the mercury-dropping electrode, the difference of potential of these electrolytes against any other metals can also be determined. In this manner, therefore, the whole subject of the differences of potential between metals and electrolytes has een made amenable to measurement.

kind have as yet been made; in the following table some numbers are given :---

			HOI	HBr	HI	H.SO.
Zn		•	-0.54	-0.46	-0.30	-0.62
Cd Sn	•	•	- 0·24 + 0·02	-0·18 + 0·12	-0.08 +0.28	-0.52 -0.03
Pb	:	:	+0.03	+ 0.10	+0.26	-0.04
Cu	•	•	+ 0.35	+ 0.35	+ 0.36	+0.46
Bi Sb	:	•	+0.41	+ 0·47 + 0·60	+ 0.60	+0.46
Ag	•		+0.57	+ 0.51	+0.15	+ 0.73
$_{ m Hg}$	٠	•	+0.57	+ 0.20	+ 0.44	+ 0.86

The values refer to 'normal' solutions of the electrolytes mentioned, and indicate the potential of the metal when that of the electrolyte is put equal to zero.

We see that those metals which dissolve in the acids become acgative; the others become positive. The values are also in very nearly the same order as the corresponding heats of reaction, but, as a calculation shows, they are not proportional. The nature of the electrolyte has generally a smaller influence than that of the metal, but there are cases where the reverse is

It should be mentioned that nearly the same numbers are obtained when salts of the acids. with metals which are not precipitated by the metal under examination, are used instead of the acids themselves. The difference of potential between the metal and the electrolyte depends, therefore, chiefly on the negative ion of the latter. From the numbers in our possession it is seen, for instance, that in the Daniell cell. whose difference of potential is 1.08 to 1.10 volt. the greater part of this (0.62 volt) is present at the bounding surface between zine and zine sulphate, and the smaller part at the surface (0.46 volt) between copper and copper sulphate.

No further conclusions of more general interest have as yet been drawn from these num-

Galvanic polarisation. When two metal plates are introduced into an electrolytic liquid and a galvanic current is made to pass through the electrolyte by means of the plates, these plates generally become the scat of a new electromotive force which acts in opposition to the current already active. This phenomenon is called galranic polarisation, and it may be perceived by connecting the plates with a galvanometer immediately after breaking the primary current.

The cause of this phenomenon is to be found in the change which is produced by the current at the boundary surface between the metal and the electrolyte. There the ions of the electrolyte separate out, and cause changes of the most manifold kind.

The simplest case occurs when the metal plates are surrounded by the solution of a salt which contains the same metal, for such a system scarcely exhibits the phenomenon of polarisation at all; such electrodes are 'un-polarisable.' The reason is that in this case the changes occurring at the electrodes do not change the condition of the bounding surfaces. But few trustworthy measurements of this If, for instance, we have zinc in zinc sulphate.

sine is separated out at the cathode, and this combines with the metal present without changing it, and at the anode SO, separates out, which then dissolves zine and forms zine sulphate. The only effect is that the zine sulphate solution becomes more concentrated at the anode, and accordingly a small concentration-current can be observed, whose electromotive force is, however, very inconsiderable.

Such a system of unpolarisable electrodes differs from all similar combinations in that it allows any, even the smallest, current to pass through. Polarisable electrodes do not behave thus. If, for instance, two platinum plates are placed in dilute sulphuric acid, and a current of small electromotive force - say, 0.1 volt-is allowed to pass, we observe by the galvanometer that at first a motion of electricity takes place, but that this ceases after a very short time. It is a phenomenon such as a condenser exhibits on being charged, with this difference, that the capacity of such electrolytic condensers appears to be very great. • On increasing the electromotive force, a corresponding quantity of electricity answering to a greater charge of the condenser always enters, but no permanent current is produced until the electromotive force is somewhat more than 2 volt; then a more copious passage of the current suddenly takes place, and simultaneously gaseous oxygen and hydrogen appear at the electrodes.

We must, therefore, represent the phenomenon to ourselves in the following way. Between the electrolyte and the platinum plates there exists originally some one difference of potential, and in consequence the double layers form there. Now, on allowing the electromotive force to act, on the one side the difference of potential of the double layer is increased, on the other it is diminished. The corresponding process to this is the condensing charge. On increasing the difference of potential, there is a moment at which the condenser no more isolates under the influence of the electro-static effects; a passage of electricity from the metal to the ions (or vice versa) occurs, corresponding to the disruptive discharge of the condenser, and the ions, deprived of their electric charges, separate out. When sulphuric acid is the electrolyte, the ions are H, and SO4; the latter substance is not stable, and reacts with the water present to form sulphuric acid and oxygen, the latter escaping in the gaseous state.

From this we see that a difference of potential of definite magnitude must exist when the electricity is to leave an ion in order to travel to a metal; until this difference of potential is reached, the system acts at the electrode like an isolator. But why does this not occur with unpolarisable electrodes? The answer to this question follows from the consideration of the processes occurring at these electrodes. Let us again take zinc plates in zinc sulphate, and let us lead positive electricity into one plate. This electricity can at once enter into the solution, by using as its vehicle a corresponding number of zinc atoms, which travel with it as positively charged zinc ions. At the other zinc plate an equal number of zinc ions can also deposit at once, and since there exists no difference of potential between zinc and zinc these can at once deliver up their electricity. Here, therefore, no cause exists for condensing effects. It is not, however, as if no difference of potential existed between the metals and their solutions; such differences, in fact, are present, and hence also corresponding double layers are formed, which at one side are made up of ions. But these do not act as condensers, free communication of their ions between the metal and the electrolyte being possible, and consequently the difference of potential, independent of the current, maintains itself at an unaltered value.

Beside the unpolarisable electrodes and those polarisable at both sides, there still exist combinations in which polarisation occurs only at one side, mostly at the cathode. This takes place, for instance, with copper plates in dilute sulphuric acid. At the cathode, when the electromotive force is sufficient, hydrogen separates out, just as it does at a platinum plate. But at the anode, on the other hand, copper sulphate is formed by the ion SO, acting on the copper—i.e. the ion SO, need not give up its negative electricity there, since in its stead positive electricity fixed to copper comes out of the plate. Hence, no polarisation occurs here.

From what has been said an explanation follows of the cause of the polarisation current, which occurs after breaking the primary current and connecting both plates in the opposite direction. It is, in brief, the discharge of the electrolytic condenser. Looking at the process more in detail, we see that when the charge in the double layers is formed, the electricity led in has remained in the electrodes, equal quantities of the opposite electricities having collected from the electrolyte on the electrodes -the electricity being, of course, bound to the ions. On the primary current being broken, and the electrodes being connected with each other, the electricities present in these neutralise each other, and the ions, which are no longer fixed, form the carriers of the current in the electrolyte. This lasts until the original condition of equilibrium has re-established itself.

In accordance with what has been said, the measurement of galvanic polarisation refers assume, or to the value of the difference of potential at which the double layer condenser no more isolates.1 The measurement of this quantity is somewhat difficult; because, when carrying out the simple experiment indicated above-i.e. when increasing the primary current up to decomposition, interrupting it, and afterwards connecting the electrodes with an electrometer-we observe that (in consequence of the secondary effects) the electromotive force of polarisation decreases very rapidly. We are, therefore, not sure whether a considerable portion of the polarisation has not already been lost in the time which elapses before the measurement. But there exists a means of obtaining information concerning the magnitude of the possible error. If the change of connections is carried out more and more quickly, increasing values at first are observed. But these approach

1 It must be observed that complete isolation does not occur; a small amount of percolation of electricity takes place when the maximum value is not reached. But, as Helmho's has shown, this phenomenou is a consequence of electrolytic convection, and is of a secondary character.

to a maximum, and when the number of current reversals reaches about 100 per second a further rise in the velocity no longer produces an increase, as was found by Raoult (A. Ch. [4] 2, 326), and the value observed under these conditions may be regarded as the correct one.

Other methods are based on making measurements of current strengths and resistances in the primary circuit, and on calculating from this the electromotive force of polarisation. These become uncertain by the fact that, owing to the processes occurring at the electrodes, the resistance of the cell undergoes variations during the passage of the current, which variations cannot be determined. Finally, we can use electrometric methods, by measuring the difference of potential between the electrode to be polarised and an auxiliary electrode through which no current passes, both before closing the circuit and while the current passes; the difference between the two magnitudes is the polarisation required. But difficulties, which have not yet been removed, appear in the practical application of this ingenious method, which was pointed out by Fuchs (P. 156, 158).

Because of these difficulties only a small number of trustworthy measurements of the electromotive force of the maximum polarisation have as yet been made. Consequently, no certain relations with chemical conditions have been discovered as yet. Though an attempt has been made to calculate the electromotive force of polarisation in a manner similar to that of the galvanic cell, from the thermal effects appertaining to it, the same objections can be raised against it as in the former case (p. 213): the observed electromotive force is generally different from that calculated.

It is especially remarkable that the maximum forces of polarisation corresponding to one and the same chemical process may be very different according to the nature of the metal. If we form galvanic cells of zinc, dilute sulphuric acid, and different metals - such as copper, silver, gold, platinum-or of charcoal, and if we close the circuit in the cells, the same process occurs in all . zinc sulphate is formed, and, to make up for it, hydrogen is expelled from the sulphuric acid. The latter appears at the metal, and polarises it. It is found that the electromotive forces of these cells, even after they have completely polarised themselves, are distinctly different; according to the nature of the second metal. a greater or less portion of the energy liberated by the reaction $Zn + H_2SO_4 = ZnSO_4 + H_2$ is transformed into electrical energy.

The cause of this can be understood after what has already been explained. The electricity must overcome unequal differences of potential in passing from the H ions to the different metals; hence different portions of the total available energy are used, and only the residue of this energy finds its expression in the electromotive force of the cells. We see, then, that the electromotive force cannot possibly bear the simple relation to the heat of reaction which was formerly supposed to be the case. But it is possible that the equation of Gibbs and Helmhoffz (p. 214) is applicable to galvanic

polarisation also; if this is so we shall be able, from a knowledge of the electromotive force and its changes with the temperature, to draw conclusions as to the thermal changes due to the processes which primarily participate in the polarisation.

VI. FREEZING-POINTS OF SOLUTIONS, METHODS BASED ON; v. MOLECULAR WEIGHTS, vol. iii. p. 417; and ELECTRICAL METHODS, this vol. p. 186.
VII. QPTICAL METHODS.—Section 1;

VII. OPTICAL METHODS.—Section 1: REFRACTION AND DISPERSION. When a ray of light passes at an angle from a rarer into a denser medium, it is always reflected towards the perpendicular, the sine of the angle of incidence being in a constant ratio to the sine of the angle of refraction, namely the ratio of the velocities of wave propagation in the two media. This constant ratio is called the index of refraction, and is generally represented in England by the Greek letter μ , and on the Continent by n: $\mu = \frac{\sin i}{\sin i}$. The angle of incidence

being in such case greater than the angle of refraction, the index of refraction will be greater than 1. The reverse will be the case when the ray passes from a denser to a rarer medium.

The refraction of a ray of light is, however, always accompanied by another phenomenondispersion, as the ray is made up of a number of vibrations of different velocities which are affected diversely in passing from one medium to another. This causes the ray of common or white light to be spread out into a number of coloured rays corresponding to vibrations of different rapidity. In all precise determinations, therefore, a definite point of the spectrum thus formed must be measured for refraction, and two such points for dispersion. The work of early observers on the refraction of light is usually wanting in precision in this respect. the records being commonly described as having reference to the bright or yellow part of the spectrum, or to the extreme red; while they furnish no data at all for calculating the dispersion. Moreover, as each colour occupies a certain breadth in the spectrum, and the boundaries of the colours are not well defined, it is by no means certain that two observations made on the same colour will refer to exactly the same part of the spectrum. In more recent observations the most conspicuous lines of the solar spectrum, such as A, D, F, H, are adopted, or, if artificial light be used, the a, B, and y lines of the hydrogen spectrum; these are recorded as $\mu_{A_1} \mu_{D_2}$ &c.; $\mu_{\alpha} \mu_{\beta}$, μ_{γ} . The greater part of the English data of recent times are given for the solar lines, while foreign observers have generally adopted the hydrogen lines.

Refraction and dispersion equivalents. The index of refraction, minus unity, when divided by the relative density (d) and multiplied by the atomic weight if an element is examined, or by the molecular weight if a compound is examined (P), is usually represented by the for-

mula P
$$\frac{\mu-1}{d}$$
 in England and P $\frac{n-1}{d}$ on the

Continent, and is termed the refraction-equivalent. It will be expressed in this article by the simple letter B. When Lorenz's formula is used,

See, however, a recent investigation by M. Le Blanc (2 P. C. 8, 299).

 $\left(\frac{\mu^2-1}{\mu^2+2}\right)^{\mathbf{P}}_{\mathbf{d}}$, the refraction-equivalent so calculated will be distinguished as & The part of the spectrum to which the observation refers will be indicated by adding the sign for infinity, or the letters of the solar or other lines observed, as R_{∞} , R_{λ} , R_{α} , &c. The dispersion-equivalent represents the difference between the refraction-equivalents of two selected portions of the spectrum; thus the dispersion-equivalent for H-A will be expressed as

 $\frac{(\mu_{\rm H}-1)}{d} - \frac{(\mu_{\rm A}-1)}{d}$, or, more briefly $\frac{\mu_{\rm H}-\mu_{\rm A}}{d}$.

multiplied by P; or $R_H - R_A$.

The index of refraction of solids is generally ascertained by the method of total reflection, unless they are transparent, and can be cut into the form of a prism; that of gases is best determined by interference. The refraction of liquids is most conveniently arrived at by placing the substance in a hollow prism, with sides of plate glass; on the prism being so adjusted that the incident and emergent rays make equal angles with the refracting surfaces, the minimum deviation will be arrived at. Let D be the deviation, i and r the angles of incidence and refraction, and a the refracting angle of the prism; then

$$\frac{\sin e \, i}{\sin e \, r} = \frac{\sin e \, \frac{1}{2} (a + D)}{\sin e \, \frac{1}{2} a} = \mu.$$

Newton, acting upon the emission theory, proposed $\frac{\mu^2-1}{d}$ as representing the absolute refractive power of any substance, and this formula met with general adoption till recent times. Gladstone and Dale (T. 1863), as the result of a long series of experiments with different substances at various temperatures, found that the refractive index, minus unity, multiplied by the volume, gave nearly a constant. To $\mu-1$ they accordingly gave the name of 'refractive energy' as really representing the influence of the substance itself on the rays of light; and to $\frac{\mu-1}{d}$ that of 'specific refractive energy. This empirical formula has been adopted by most subsequent investigators; and Sutherland (P. M. [5] 27, 141) has lately advocated it on mathematical, as well as on physical, grounds. It holds its position side by side with the theoretical formula we have now to

Lorenz's formula. H. A. Lorentz, of Holland (W. 9, 641), and L. Lorenz, of Copenhagen (W. 11, 70), came almost simultaneously to the conclusion, from purely theoretical considerations, based, in the case of the former, on the electro-magnetic theory, that $\frac{\mu^2-1}{(\mu^2+2)d}$ must express the relation between the velocity of the transmission of light and the density of the medium through which it is propagated. Landolt (B. 15, 64) tested the comparative merits of this formula, and that which he had previously adopted—viz. $\frac{\mu-1}{d}$ —and found that so far as liquids were concerned there was nothing to choose between them, but that Lorens's formula showed much less difference between the specific refractive energy of a liquid

consider.

and that of its vapour. This is shown in the following table, in which it will be also noticed that the difference with the rise in temperature is uniformly plus in the one case, and minus in the other. Weegmann (Bonn. 1888) experi-menting at 10°, 20°, and 30°, noted the same rise in the one case and fall in the other.

Substance	State	Temp.	$\frac{\mu_{\rm D}-1}{(\mu_{\rm D}+2)d}$	$\frac{\mu_{\rm D}-1}{d}$
Water Ethyl alcohol Ethyl ether. Ethyl acetate Ethyl lodide Chloroform.	Liquid Vapour Liquid	10° 20° 100° 10° 20° 100° 100° 100° 20° 100° 20°	0-2062 0-000 0-2061 0-0007 0-2061 0-0007 0-2804 0-0007 0-2805 0-0018 0-3026 0-0007 0-3026 0-0007 0-3028 0-003 0-2547 0-0007 0-2683 0-1557 0-1557 0-0007 0-1557 0-0007 0-1571 0-0007	03101 0-0255 0-0255 0-0301 0-1011 0-1
Carbon di- sulphide .	Vapour Liquid "Vapour	100° 20° 100°	0·1796 0·2805 0·2809 0·008 0·2898	

In the case of liquid and solid phosphorus, as well as of other highly refractive bodies, the empirical formula appeared to give the best results. Landolt also found the simpler formula best adapted to his process of optical analysis subsequently described. But while he found that the refraction-equivalents (i.e. the specific refractive energy multiplied by the atomic weight in the case of elements, or by the molecular weight in the case of compounds) of substances calculated by Lorenz's formula are about onethird smaller than the numbers calculated by the formula previously adopted by him, the values which he obtained for the elements carbon, oxygen, hydrogen, and chlorine did not bear the same proportion. Adopting Brühl's figures for R_{α} (as described later on), the values according to Lorenz's formula vary from about 1 to 3 the values found by using the other formula. Thus :-

	Old Formula	Lorens's Formula
Carbon	5.0	2.48
Hydrogen	1.3	1.04
Oxygen, alcoholic	2.8	1.58
" aldehydic	3.4	2.34
Chlorine	9.8	6.02
Increase for double carbon bond	2.4	1.78

Brühl, however, in 1886 (A. 235, 1), maintained that the statement of Landolt, that the two formulæ lead practically to the same conclusions in respect to chemical constitution and the refraction of light, cannot any longer be accepted in its general sense. In this paper Brühl contended that the expression of the molecular refraction hitherto used—viz. $P = \frac{\mu - 1}{d}$ is generally adapted only to the paraffinoid series of carbon compounds, and for unsaturated compounds of

weak dispersive power; and that in these cases even the results are not altogether satisfactory. For the investigation of the relations between the refractive power and the constitution of bodies, Brühl claimed that in future Lorenz's formula must be used. The tables appended to the paper certainly show better proportionate results for Ra by this formula, especially in the case of the most dispersive substances; but in using these tables it must be borne in mind that the values assigned to the elements under the two formulæ are not strictly comparable. Nasini (Lincei, Rc. 3, 128) stated that he and Bernheimer did not consider that, from a chemical point of view, any great preference should be given to Lorenz's formula over the formula d, as the newer formula was insufficient to

represent every relation between the chemical constitutions of the substances and their refractive powers. Ketteler does not accept the Lorenz formula as altogether satisfactory; in place of it he has proposed $\frac{\mu^2-1}{(\mu^2+x)\cdot l}$, where x is

a variable quantity depending on the nature of the substance, but averaging about 3.5 instead of 2. Sutherland (P. M. [5] 27, 141) objects to Lorenz's formula on the ground that it assumes a mean wave length, whereas the wave length must vary in passing from ether to matter; and he maintains that while the formula holds good for both the liquid and gaseous states, it fails when change of density is produced by change of pressure. On the other hand, he thinks that Gladstone's formula meets the last requirement, but fails to bridge over the great gap in density between liquid and vapour. Ketteler (Z.P. C. 2, 905) suggests an equation of the form $(n^2-1)(v-\beta)$ M, where β is the volume actually occupied by the ponderable molecules, v that of the space in which they are contained, and M a molecular function depending on the constitution of the medium. M may have one of two values, both of which are definite constants, the one for the liquid and the other for the gaseous state. The value of β may be obtained by varying the temperature, the pressure, or the constitution of the media examined. Sutherland says that this formula gives for compressibility results less satisfactory than those given by that of Gladstone.

Zehnder (W. 34, 91) investigated the influence of pressure upon the index of refraction of water at different temperatures, and on comparing the results with the co-efficient of compressibility, he came to the conclusion that the formula $\frac{\mu-1}{d}$ was practically exact -much more so than that of Lorenz. Röntgen and Zehnder (W. 44) have since applied the same inquiry to CS2, and CaHe, ether, and a series of alcohols, with the result that in the cases of all these substances neither formula is sufficiently exact, the experimental figures occupying very nearly the mean place between those given by the two formulæ. Perkin (C. J. 61, 287) in studying magnetic

rotation at widely different temperatures, observed a slight reduction as the temperature was raised. Dale and Gladstone (as long ago as 1868) had observed that the specific refractive 1868) had observed that the specific refractive tains three unknown quantities, it requires for energy of substances was similarly affected; their determination three simultaneous equa-

Nasini and Bernheimer (G. 15, 59) in 1885, and Ketteler (W. 33, 506, 662) in 1888, also found small differences in the same direction. Perkin accordingly made a series of experiments to

see if the changes in $\frac{\mu-1}{d}$ due to temperature

vary with different classes of substances, as they do in the case of the magnetic rotation. The results seem to corroborate this, though not very definitely. On trying Lorenz's formula, he found the refraction rise with increase of temperature, and he came to the conclusion that this formula is not suitable when dealing with high tempera-

Guye (Ar. Sc. Genève, 23, 197, 204) pointed out a relation between the constants of the equation of Van der Waals and that of the formula of Lorenz for the refraction of light. He maintained that the relation of the absolute critical temperature to the critical pressure, which he termed the 'critical co-officient,' is proportional to the molecular refraction, and that it furnishes a valuable means of determining the molecular constitution of bodies at the critical point. By a comparison of the data given by a number of observers for forty different substances he obtained the result that the critical co-efficient (K) is in proportion to R as 1 to 1.8. The experimental difficulties connected with the determination of K, and the fact that Guye had not always the data for reducing R observed to Roo, rendered the final results less uniform than they might be otherwise; but the extreme range of his factor varied from 1.6 to 2.0, giving 1.8 as a mean. Guve found, however, certain classes of bodies which gave a different factor to that above mentioned. Such gases as O, N, and CO, gave a factor ranging from 1.1 to 1.4. Water gave 1.1, and methylic alcohol 1.1 to 1.2. He also recorded some which are exceptionally high, but in most of these cases the results of the experiments seem untrustworthy in consequence of chemical action having taken place. Having determined his factor, he was able to divide by it the recognised refractions of the elements according to Brühl, and so to get what he termed the 'atomic critical co-efficient,' from which he could build up the critical co-efficient of any substance of which the theoretical constitution was determined.

Dispersion formulæ. As the observations of Gladstone extended to the solar line A, his calculations were but slightly affected by dis-persion; whereas nearly all the Continental observers have used the hydrogen light, and have no actual measurements below the line a. They have, therefore, usually sought to get rid of the effect of dispersion by adopting one or other of the suggested formulæ for calculating the theoretical ray of infinite wave length, and have worked out their results both for the observed line a, and for the assumed limit. The simplest of these methods, and on that account the one most generally adopted, is that of Cauchy. It is usually expressed by the formula

$$\mu = \mathbf{A} + \frac{\mathbf{B}}{\lambda^2} + \frac{\mathbf{C}}{\lambda^4} + \dots$$

in which A represents the wave length of any given line of the spectrum. As this formula con-

tions: but the third term is often dispensed with ! to reduce the amount of calculation required. By the process of elimination, the values of A, B, and Care obtained, A being Cauchy's co-efficient of refraction, and B and C the co-efficients of dispersion. This theory accords fairly with the experimental data for substances of moderate dispersive power, though by no means well with the data for substances of high dispersive power, such as oil of cassia. Wüllner (A. 133) considered that this formula was sufficiently exact for bodies of low dispersive pover when two constants were used; but that for highly dispersive substances, such as carbon disulphide, it was necessary to go to the third term, as the difference between the observed value of us and that calculated from μ_a and μ_{γ} amounted to as much as 0.0022; while on using three terms the calculation was correct to the fourth decimal place. He also tried the formula of Christofle

$$n = \frac{n_0 \sqrt{2}}{\sqrt{1 + \frac{\lambda_0}{\lambda}} + \sqrt{1 - \frac{\lambda_0}{\lambda}}}$$

in which n_0 and λ_0 signify two selected constants, and n is the corresponding index of refraction of the wave length A; this also gave results which were not sufficiently accurate. Taking the observed indices for the lines a and y of carbon disulphide at 0° as 1.634066 and 1.692148, this formula gave 1.669397 for β , while the observed value was 1.669076. At 20° the calculated value for \$\beta\$ was as much as 000494 too high. Langley (P. M. [5] 17, 194) has discussed the relative merits of Biot's, Cauchy's, and Redtenbacher's formulæ, and has come to the conclusion that while each of them is sufficiently exact within the limits of the visible spectrum, they soon begin to give too small results for μ when that limit is passed. Biot's formula

$$\frac{1}{n^2} = a + b \binom{n^2}{\lambda^2} + c \binom{n^4}{\lambda^4} + k \binom{\frac{\lambda^2}{n^2}}{n^2}$$

gives more trustworthy results than either of the

Redtenbacher's formula $\frac{1}{n^2} = a + b\lambda^2 + \frac{c}{\lambda^2}$ has the serious objection that it reached a minimum at a point corresponding to n = 1.5647 in the prism which he employed, so that for every value of n greater than 1.5647 it gave two different values for λ . Langley has experimentally determined wave lengths in the invisible prismatic spectrum far beyond the extreme limit possible according to Cauchy's formula. Brühl, after working out his results for R_∞ as well as for R_a, has latterly (A. 235, 1; 236, 233) come to an adverse conclusion as to the utility of Cauchy's co-efficient of refraction for getting rid of the effect of dispersion, and he even asserts that when three terms are used the results are less to be relied upon for this purpose than when two terms only are employed. The following table shows the differences in Cauchy's A when calculated with two and Cauchy's A with calculated with two three terms respectively, from the observed indices μ_{α} and μ_{γ} in the former case, and from μ_{α} , μ_{β} , and μ_{γ} in the latter; and also μ_{α} as observed, compared with the same index of refraction as calculated by Cauchy's formula from μ and μ_{γ_i} showing in this case a difference

of from one to five units in the third place of decimals :--

	Cauch	y's A	μρ		
Substance	2 terms	3 terms	Ob- served	Cal- culated	
Benzoyl chloride Orthotoluidine Clinnamic alcohol Aniline Furfurol Cinnamic aldehyde	1:51:006 1:53715 1:54307 1:54741 1:48269 1:55:066	1 52700 1 54460 1 55253 1 55689 1 49816 1 58256	1.56964 1.58945 1.59993 1.60434 1.54566 1.65090	1 57097 1 59069 1 60151 1 60592 1 54824 1 65622	

In the case of substances of small dispersion, Brühl regards the use of Cauchy's formula as superfluous; with substances of medium dispersion, the results are generally preferable to those for the line a, though not to any great extent; but with substances of great dispersive power the differences are too great to be neglected in considering questions of chemical structure.

Nasini (Lincei, Atti, 18 [3]) comes to the same conclusion, that Cauchy's co-efficient of re-fraction ought to be rejected in studies of this nature, and that his co-efficient B is still more misleading if it be regarded as a measure of dispersion. N. (Lincei, Atti, 19 [3]) had already tested the merits of several formulæ, and given the preference to that of Lommel as affording better results than those arrived at by Cauchy's formula with two terms. The following table will show the differences between μ_{β} as observed, and as calculated by these two formula :-

Substance	μρου-	Calcu	lated	Difference		
Substance	served	Cauchy	Lommel	Cauchy	Lommel	
Benzene. Aniline. Methyl-a-	1·51339 1·60434			0.00065 0.00158	0.00088 0.00088	
naphthol .	1.64597	1.6477	1 64678	0.00173	0-00081	
naplithalene	1.63200	1.6330	1.6324	0.00100	0.00010	

Weegmann (Bonn., 1888) gives reasons why Cauchy's formula for the limit of the spectrum is not to be relied upon; and maintains that his B, or co-efficient of dispersion, must not be taken as a measure of dispersive power, but that it should in any case be divided by the relative density.

Helmholtz has proposed the formula
$$n^2 - 1 = Q_{\frac{\lambda^4}{\lambda^2 - \lambda^2 m}} - P\lambda^2$$

in which n and λ represent the index of refraction and the corresponding wave length, and Q, P and A2m are three constants dependent upon the nature of the medium. Ketteler has

$$n^2-1=\frac{A}{\lambda^2-B}+\frac{C}{\lambda^2-D}+\cdots$$

subsequently proposed another, viz. $n^2-1 = \frac{A}{\lambda^2-B} + \frac{C}{\lambda^2-D} + \cdots$ Brühl has tested the comparative merits of both these tested the comparative merits of both these formulæ, as well as that of Cauchy. Taking Gladstone and Dale's observations of a solution of phosphorus in carbon disulphide, he calculated the values of the lines B, D, F, and G from the observed values of A, E, and H, and again those of A, B, E, and G from those of D, F, and H. The following table above the differences in the two cases between the observed and calculated values (A. 286, 238):

Line	4	observed	Canchy	Helmbo:tz	Ketteler	Cauchy	Helmholts	Ketteler	
_	7.606	1.9209				+19	+48	+108	i

H	8.956	2-0746		۱ ۱					

The difference between Dispersive power. the indices of refraction of the rays of the spectrum of any refracting medium is termed the 'dispersion'; and by the dispersive power of a substance is expressed the ratio of the co-efficient of dispersion to the index of refraction of the mean ray minus unity. Thus taking the full length of the visible spectrum as extending from A to H, and F as the mean ray, the dispersive power would be represented by the formula, $\mu_{II} - \mu_{IA}$. $\mu_{IV} - 1$ Ketteler (Theoretische Optik, Braunschweig,

1885) has proposed two formulæ for dispersion based upon theoretical grounds:

$$\frac{\mu_n^2-1}{\mu_m^2-1}$$
 and $\frac{\mu_n^2-\mu_m^2}{\mu_n^2-1}$

 $\frac{\mu_n^2-1}{\mu_m^2-1} \text{ and } \frac{\mu_n^2-\mu_m^2}{\mu_n^2-1}$ when n is a ray more refractive than m. Costa (G. 19) regards these as having the advantage over the formula $\frac{\mu_n - \mu_m}{d}$ on account of their being independent of the density of the

medium. Early experiments. Newton, Herschel, Young, Wollaston, Browster, and others deter-mined the indices of refraction of a large number of solids and liquids, in most cases for the yellow or brightest part of the spectrum. The index for the solids ranged from 1:111 for tabasheer to 2.974 for chromate of lead, and for liquids and soft solids from 1.0570 for ether expanded by heat to thrice its volume, to 1.678 for disulphide of carbon, and about 1.8 for chloride of antimony (Encyc. Brit., 8th edit. Optics, 558).

Arago and Fresnel applied the method of interference to the comparison of the refractive indices of moist and dry air, with the result that moist air was found to be rather less refractive than dry air. Dulong determined the indices of refraction of a considerable number of gases and vapours.

Dulong, together with Arago, Biot, and others, adopted the formula of Newton $\frac{\mu^2-1}{d}$, and

came to the following conclusions; that the refractive power of a mixture of gases is equal to the mean of the refractive powers of the constituent gases calculated for the pressure to which each gas is actually subjected in the mixture, and that the refractive power of a compound gas is not equal to the mean of those of the component gases, but is sometimes greater and sometimes less.

Höck also found this formula to apply to some mixtures of liquids, and Schrauf (P. 133, 479) has more recently supported the same mode of calculating the refractive power; but Ketteler (P. 124, 890) found that liquid sul-Voz. IV.

phurous acid was not accordant with the known refraction of the gas as arrived at by the formula $\frac{\mu^2-1}{d}$, while the two came into agreement when he adopted the modern formula for the specific refractive energy $\frac{\mu-1}{d}$.

Jamin (A. Ch. [4] 3, 49) made careful experiments on the influence of the presence of aqueous vapour in the atmosphere upon the refractive index, and he found that the difference between the refractive indices of dry air and air saturated with aqueous vapour was only 000000726, a quantity so small that it may be safely neglected in the calculation of atmospheric refraction for astronomical purposes.

Ketteler (B. B. 1865) adopted Jamin's interference refractor for the measurement of the index of air, CO₂, CN, H, and SO₂, for the line D. He calculated the lithium and thallium lines from the wave length of the sodium line, according to the proportional number of rulings that coincide, it being found that this is independent of density and is a true function of the wave lengths.

RELATIONS BETWEEN PHYSICAL AND CHEMICAL PROPERTIES AND REFRACTION OF LIQUIDS.

Dale and Gladstone (T. 1858, 887) made an elaborate series of experiments on what they then termed the sensitiveness of liquids, or the effect of temperature on the refractive index. The principal conclusions they arrived at were that both the index of refraction and the length of the spectrum, $\mu_{\rm H} - \mu_{\rm A}$, diminish as the temperature rises, and that the sensitiveness of a substance is independent of its specific refractive or dispersive power. These conclusions were the result of observations on CS2, Et2O, H2O, P alcohols, &c. The following table and the table on p. 226 give the data for CS2 and H2O: -

Carbon disulphide (b.p. =43°)

Temp.	μ	μ _D	μ _{ιτ}	Sensi- tiveness	μ _Η μ _Α	Disper- sive power
0° 5° 10° 15° 20° 25° 30° 35° 40° 42.5°	1-6217 1-6180 1-6144 1-6114 1-6076 1-6036 1-5995 1-5956 1-5919 1-5900	1·6·442 1·6·397 1·6·346 1·6·303 1·6·261 1·6·290 1·6·182 1·6·140 1·6·103 1·6·082	1.7175 1.7119 1.7081 1.7085 1.6993 1.6942 1.6896 1.6850 1.6810 1.6778	0*0045 0*0051 0*0043 0*0042 0*0011 0*0038 0*0042 0*0042	0-0958 0-0939 0-0937 0-0921 0-0917 0-0906 0-0901 0-0891 0-0878	0-1489 0-1407 0-1477 0-1462 0-1463 0-1460 0-1457 0-1456 0-1459 0-1443

The sensitiveness is reckoned from the indices of the line D, and the dispersive power repre-

sents $\frac{\mu_{\rm H} - \mu_{\rm A}}{\mu_{\rm D} - 1}$. The sensitiveness indicates an anomaly in water, which has also been observed by others.

Gladstone and Dale (T. 1863. 317) extended the same inquiry to the following five points:— (1) the relation between sensitiveness and the change of volume by heat; (2) the refraction and dispersion of mixed liquids; (3) the refraction, dispersion, and sensitiveness of different members of homologous series; (4) the

	Water

refraction, dispersion, and sensitiveness of isomeric liquids; (5) the effect of chemical substitution on these optical properties. As to the first point of the inquiry, they came to the conclusion that the specific refractive energy

 $\left(\frac{\mu-1}{d}\right)$ is a constant not affected by temperature. They made the reservation, however, 'that there is some influence, arising wholly or partially from dispersion, which gives rise to the slight progression of most of the calculated products, and perhaps to the non-inversion of the sensitiveness of water at 4°, remarked on already by Jamin and ourselves.' As to the second point of inquiry, it was found 'that the specific refractive power of a mixture of liquids is the mean of the specific refractive powers of its constituents,' subject to some slight exceptions, as in the case of sulphuric acid and water. The inquiry into the refraction, dispersion, and sensitiveness of different members of homologous series showed a progressive increase in the specific refractive energy as the series advanced; but that the influence of each addition of CH., which is observable throughout the series of the methyl group, does not necessarily hold good with reference to substances of quite another type. The observations on isomeric bodies showed that some of them are widely different in their optical properties; but that those which have a close chemical relationship show an identity in their optical properties also. In the last branch of the inquiry it was sought 'to determine the amount of change in the optical properties which results-from a replacement of one element by another, the type remaining the same,' in order to 'attain to a knowledge of the influence of the individual elements on the rays of light transmitted by them.' The general conclusion of Gladstone and Dale was that every liquid has a specific refractive energy composed of the specific refractive energies of its compound elements, modified by the manner of combination, and which is unaffected by change of temperature, and accompanies it when

question which has since occupied the attention of many observers.

Landolt (P. 117, 122, 128) took up the inquiry, adopting the formula $\frac{\mu-1}{d}$ used by

mixed with other liquids.' This opened up a

Gladstone and Dale, and applied it in the first instance to an investigation of the values of C, H, and O. He simplified the investigation by multiplying the specific refractive energy by the molecular weight of the compound, which gave P $\frac{\mu-1}{d}$ as the molecular refractive power, or refraction equivalent, terms which had already been applied by Berthelot and Schrauf to the formula P $\frac{\mu^2-1}{d}$.

By comparing series of homologous compounds, acids of the series $C_nH_{2n}O_2$, alcohols of the series $C_nH_{2n}O_2$, and esters of the series $C_nH_{2n}O_2$, L. obtained the increment due to each addition of CH_2 as shown in the following selection from his data:—

The mean of Landolt's comparisons gave the value R=7:60 for CH₂. Dealing in the same manner with compounds differing by one atom of carbon, by two atoms of hydrogen, and by one atom of oxygen, respectively, he assigned to the several elements the following refraction-equivalents; C=5:00; H=1:30; O=8:00. Subsequent investigations would lead one to reject several of the substances which he brought into comparison.

Landoit also adopted a modification of Biot and Arago's formula for mixtures of gases, by substituting n for n² throughout, so that

$$\frac{N-1}{D}P = \frac{n-1}{d}p + \frac{n'-1}{d'}p' + \cdots$$

N, D and P representing the index of refraction, density, and 'molecular weight' of the mixture, and the small letters the same values of the several substances forming the compound. In this manner he calculated the value of n_c or n_c for mixtures of liquids as shown in the follow-

ing table. It will be seen that the calculated and observed values correspond very closely.

Refraction-equivalents of the elements. Gladstone (T. 159, 18; Pr. 18, 49) applied Landolt's P $\frac{\mu-1}{d}$ to inorganic compounds in order to arrive at the refractionequivalents of the several elements, and also to determine whether or not any of the elements had more than one definite refraction-equivalent. As most of his observations were made upon crystalline salts, many of which were doubly refracting, Gladstone adopted the plan of dissolving them in water, or alcohol, and deducting from the R of the solution the R due to the solvent. This mode of operation was supported by the consideration that in the cases of rocksalt and sugar, where the refraction equivalent of the substance has been obtained both in the solid and dissolved condition, it is found to be the same. Ca comparing a series of salts of K and Na, it was evident that, while the refractionequivalents of the compounds differed very widely, according to the nature of their negative constituents, the refraction-equivalents of the compounds of Na differed pari passu with those of the K compounds, and hence it was concluded that the negative constituent has the same effect on light, whichever metal it is united with. Values were arrived at for forty-six of the elements, a number which has been subsequently somewhat increased; and more recent investigations have led to slight modifications in the figures. The latest list is as follows: -

Anomalies were pointed out in the refractionequivalents of the hydracids, and of the benzenoid carbon compounds. With regard to the specific refractive energy it was remarked ;-First, hydrogen has more than double the energy of any other element, even in the lowest number that Second, phosphorus, can be assigned to it. vanadium, titanium, and sulphur have singularly high energies, and they are substances that present certain chemical analogies. Third, there are several pairs of analogous elements having nearly the same energy; thus bromine and iodine, arsenic and antimony, potassium and sodium, manganese and iron, nickel and cobalt. Fourth, an element in altering its valency alters its energy. Fifth, if the metals are arranged in the order of their energies, they are, with few exceptions, in the inverse order of their atomic weights.

Benzenoid hydrocarbons.—The anomalous refraction and dispersion of the hydrocarbons already referred to was treated in a paper by Gladstone (C. J. 23, 147), the tables in which indicated that the values for all these bodies and their derivatives were largely in excess of the normal, calculating R_A of carbon at 5·0. The refraction-equivalents of the typical hydrocarbons were expressed as in the following table; but while the physical fact indicated has been fully verified by subsequent research, the particular numbers in the third column have been modified, and a plue has been assigned to the olefines.

A similar table is given illustrating the inereased influence on light of carbon which is combined with two atoms of hydrogen or one of oxygen, in a series of oxidised bodies obtained from essential oils, differing from one another only in the quantity of hydrogen.

Bedson and Williams (B. A. 1881, 155) tested the question whether the specific refraction of a solid body could be determined from the refractive power of its solution as stated by Dale and Gladstone, as this method had been called in question by Janovsky (Sitz. W. 82, 148). They found the specific refractive energy for the ray of infinite wave length, calculated from solutions of NaCl, Na₂B₂O₃, H₂BO₃, and NaPO₃ to be in substantial accord with the results derived from observations on the solids. They also found that the specific refraction of liquid phenol is practically identical with the value calculated from solutions in alcohol and in acetic acid.

In taking the index of refraction of solid NaPO₃, B. and W. immersed it in a liquid of greater refractive power, and then added a feebly refractive liquid until the refractive power of the mixture appeared to be the same as that of the solid suspended in it. The index of refraction of the mixture was then determined. The result being found satisfactory, the prisms of rocksalt and of fused borax were also tried by the same process, as well as in the ordinary way, and with similar results.

Double values of carbon and oxygen. Brühl, in 1879 and 1880 (A. 200, 139; 203, 1, 255), conducted a long investigation into the chemical constitution of carbon compounds in reference to their relative densities and their power to refract light. Taking up the observations of Gladstone, and also referring to some of the anomalous results in the tables issued by Landolt, whose mode of investigation suggested that the grouping of the atoms exercised a certain influence upon the refraction of light, Brühl set himself to inquire: What is the typical peculiarity which must be common to all the bodies that refract light in an abnormal manner? He usually determined the indices for the three H lines, μ_{β_1} and μ_{γ_1} and for the Na line μ_{D_1} and calculated the refraction-equivalents both for the line α , and for Cauchy's A, viz. R_{∞} . The following table is so arranged that between each horizontal line the first-named substance has the highest molecular weight, while those below differ only in having a smaller quantity of hydrogen, and, therefore, contain doubly-linked carbon atoms.

It will be observed that the density, the index of refraction, and the co-efficients of refraction and dispersion of Cauchy always increase with the diminution of H, and that the loss in specific refractive energy which is suffered by the disappearance of two atoms of H is at least fully made up by the consequent double linking of the carbon atoms. For the calculated values of the refraction-equivalents, Brühl has adopted the following values for the elements, vis.—for R. C=5-0, H=1-3, O=3-0, Cl=9-8, Br=15-3,

			T			1	1	R.

N = 5.8; the first three being the values given by Landolt, the two halogens those by Haagen, and that for N being determined by Brühl himself. From the observations recorded in the foregoing table and others, Brühl has arrived at the following conclusions:—That the closing of the chain of atoms in the form of a ring, with which so marked an increase in the density and index of refraction is associated, exercises a very special influence on the power of the substances to disperse light; that the mol. refraction of the substances in which the existence of one or more pairs of doubly-linked carbon atoms is recognised is greater than the sum of the refractions of the constituent atoms by 2.0 in the case of Cauchy's limit, and 2.3 in the case of the line H. for each such pair. For combinations of the acetylene type, including the propargyl derivatives, he gives a rather lower value, viz.: 1.8 and 1.9 respectively. These data give the following atomic refractions for earbon, viz.—

Nasini and Bernheimer (Lincei, Atti, 18) do not, however, admit Brühl's views as to the constitution of the propargyl compounds, as well as some of the other conclusions at which he has arrived. They give tables of observations on naphthol compounds, styrol, cinnamic alcohol, anethol, anisol, thymol, and diamylene, and have worked out the results by the two

Ro and Ro, as well as showing the small differences both in specific refraction and specific disperson due to differences in temperature. The principal conclusions at which they arrive are as follows:-The statement that every double bond, and only every double bond, causes the mol. refraction to increase by a constant quantity is not confirmed by complete series of substances, because in compounds containing only four or five double bonds the increase in refraction indicates a much greater number. That the increase in mol. refraction grows step by step as the compounds become poorer in H; but no proportion exists between the increased values and the number of pairs of atoms of H that is lost; nevertheless, a simple relation exists with the other structural changes in the formula, expressed by double bonds, closed chains, &c. That the augmentation increases more or less rapidly from the paraffins to the olefines, and thence to the benzenes, and again to the naphthalenes, but by what law is not evident, and is not capable of expression by our structural formulæ. They consider it established, however, that the principle is approximately valid, that in every series of compounds each atom in the molecule furnishes its fixed contribution of refraction, and that in the paraffin series the mean values of the atomic refractions coincide with those derived directly from the elements them-selves. They remark that even in the paraffin series the constancy of the atomic refractions is not absolute; because the more the mol. w. increases the greater is the difference between ordinary formula for B. and B., and also for the calculated and experimental values. For

other series the same values no longer apply, being too low, and hence other constants are required.

Kanonnikoff (Bl. [2] 36, 557) has published observations confirming Brühl's calculation of the increase due to the double bond between carbon atoms, and of the loss in specific refractive energy due to the elimination of two atoms of hydrogen being counterbalanced by the increase due to the consequent double linking of the carbon atoms.

Landolt (P. 117, 122) had determined the refraction of oxygen from a comparison of the refraction-equivalents of various substances the empirical formulæ of which differed by one atom of oxygen; and from acids of the formula $C_nH_{nn}O_n$ by deducting the value of n times CH. The results were somewhat discordant, the first series giving a mean value for oxygen of 2.76, and the latter of 3.0. The former of these manifestly represented the atomic refraction of oxygen in hydroxyl; and if oxygen varied in its refraction according to its valency it is evident that a general average resulting from these two modes of determination could not be taken. Brühl shows that, adopting Landolt's second plan for arriving at the value of oxygen in the aldehydes and ketones of the formula C, H,,O, the R_a for oxygen will average 3.4; and that chloral, butyl-chloral, and the oxychlorides give substantially the same result. On the other hand, deducting the refraction-equivalents of the aldehydes from those of their corresponding acids, of the alcohols from the glycols, and of the acids from the oxyacids, he obtains 2.75 as the mean value for oxygen. An approximate result, 2.80, is obtained if, from the ethers, $C_nH_{2n}O_2$, the value of n times CH_2 + the higher value (3.4) for one atom of oxygen be deducted. For oxygen united to carbon by a double bond Brühl therefore assigns the refraction-equivalent 8.4 for the line a; and for oxygen in hydroxyl, or generally for oxygen united to two other atoms, he gives the value 2.8; he represents the former as O" and the latter as O'.

Hence C=0 = 5.0 + 3.4 = 8.4. C=0 = 5.0 + 2.8 = 7.8.

Whether, however, the increased result of the double linking of the carbon and the oxygen is due to one of the elements only, or whether both of them share in it, he leaves an open question, though he regards the latter as the more probable. If two atoms of H are removed from a substance without involving the double linking of carbon atoms, as in the case of an alcohol being converted into an aldehyde or ketone, there follows a very marked reduction of the specific refractive energy. This reduction, however, becomes less and less marked as the quantity of C increases in the higher members of the series. When the removal of two atoms of H involves the double linking of the C, the loss of refractive energy is more than compensated by the increase due to the doubly-linked C.

A comparison of a considerable number of isomeric bodies of the paralinoid series of acids ahows that the indices of refraction of the primary and normal compounds are a little greater than those of the secondary and iso-compounds, and that the densities are proportional in the case of unsaturated compounds of similar

empirical composition, however, the double linking of the carbon atoms increases the refractive power more than the density.

In a subsequent paper (A. 235, 1), Brühl treated of the molecular refraction of organic liquids of high dispersive power. He arrived at the conclusion that the dispersion of different substances stands in no clearly recognisable relation either to their refraction or chemical constitution; and that it cannot be numerically expressed. This, however, is contested by Gladstone (Pr. 42, 401), who, while admitting that there are difficulties in the investigation of dispersion which are not felt in dealing with refraction, still holds (1) 'that dispersion, like refraction, is primarily a question of the atomic constitution of the body: the general rule being that the dispersion-equivalent of a compound is the sum of the dispersion-equivalents of its constituents; (2) that the dispersion of a compound. like its refraction, is modified by profound differences of constitution, such as changes of atomic valency; (3) that the dispersion frequently reveals differences of constitution at present unrecognised by chemists, and not expressed by our formulæ.' Brühl held that the differences which still appear between the calculated and experimental values when Lorenz's formula is used, and which he showed to be less in proportion than when the old empirical formula is used, are principally due to the influence of dispersion, and that they would in great measure vanish if this disturbing cause could be overcome; that with substances with a dispersion equal to about that of cinnamic alcohol the molecular refraction for the line a would serve as a help to the determination of the chemical constitution, but beyond that limit the numerical results are too uncertain to be of use except as collateral evidence; that there is a direct and simple proportion between the number of unsaturated groups of atoms in any compound and the increase of the molecular re-

fraction $\left(\frac{\mu^2-1}{\mu^2+2}\right)\frac{p}{d}$ over the value derivable

from the empirical chemical formula; that the effect on refraction of the acetylene combination, which he represents by \equiv , is analogous to that of the ethylene, or doubly-linked carbon, \equiv , and that it is somewhat greater, but not twice as great, as the latter.

Gladstone questions Brühl's assumption that both cinnamic alcohol and cinnamic aldehyde have four pairs of doubly-linked carbon atoms, on the ground that they have widely-different dispersions; also that allyl paracresolate and anethol are similarly constituted, for the same reason. He also thinks that the evidence as to: the constitution of cymol and hexahydro-naphthalene from Brühl's observations is not conclusive as to the one having three pairs, and the other two pairs, of doubly-linked carbon atoms, seeing that they have nearly the same dispersion. Nasini (Lincei, Rc. 3, 164) in like manner holds. that these particular compounds do not justify the conclusions that Brühl has come to respecting them, and agrees with G. that the dispersion may be a constant, and a much more sensitive one than the specific refraction; and that as such it is affected more and varies more

by certain little differences of composition and constitution of which the specific refraction does not feel the influence.

Brühl (Z. P. C. 1, 6) maintains that Erlenmeyer's constitutional formula, with five ethylene combinations, correctly represents the structure of naphthalene, and those derivatives in which hydrogen is replaced by monovalent elements. But the results of the observations on which he bases this conclusion all show a larger increment than can be accounted for by this formula: the excess he attributes mainly to the influence of dispersion. In this and all the other inquiries he has adopted Lorenz's formula, and the solar line C, without attempting to get rid of the influence of dispersion by the use of Cauchy's co-efficient of refraction. In the same paper he formulates the following six propositions:-(1) Isomerides of similar atomic arrangement (Stellungsisomere) have similar specific and molecular refractive powers; on the other hand, those isomerides which show differences of saturation (Sättigungsisomere) have various specific and molecular refractive powers; (2) polymeric combinations never show similar specific refractive energy, or multiple molecular refraction corresponding to the molecular weights; (3) transformations of multiple linkings of atoms into simple ones have as their result a diminution of refraction, equally, whatever the kind of chemical change may be (polymeric or isomeric change); (4) the optical effect of the accumulation of multiple linkings is the same, whether it produces open chains (amylene-diamylene) or ring formations with one or more groups of rings (as in paraldehyde, cymhydrene, menthol, &c. in the one case, and in turpentine and cajeputol in the other); (5) the molecular refraction of a fully saturated body is very nearly that of the sum of the refractions of the atoms of the empirical chemical formula, each of these being reckoned as united by single bonds-all those are to be regarded as saturated bodies in which there is no multiple linking of the atoms, such as the true paraffins, or derivatives of the general formula $(C_nH_{2n+2})-xH_2$; (6) all unsaturated bodies show an increased refraction which is proportional to the number of ethylene, acetylene, or carbonyl combinations present; the proportion, as a rule, is the more exact the less the substances in question are distinguished by a specially great dispersion. While holding to the opinion that the monovalent elements have virtually each but one refraction equivalent, and that the change of valency in the others is the chief cause of their variable refraction, Brühl considers that exact values cannot be obtained, because the mode of the grouping of the atoms may not be altogether without influence.

In the meantime, Gladstone (C. J. 45, 241) had brought together a large number of observations on organic compounds, both liquids and solutions of solids, and placed against them the refraction-equivalents calculated on the basis of the following values for the elements:—

Carbon, saturated .			R	₄ 5·0
$_{n}$ in $C_{n}H_{n}$.				5 ·95
" doubly linked	• *	•	•	6·1

Nitrogen				•		4.1
	in bases,	NO,	æc.	•	٠	5.1
Chlorine						9.9
Bromine.						15.3
Iodine .						24.5
Sulphur,	singly lin	iked				14.1
,, ,	doubly li	nked				16 ∙0

Gladstone's observations confirm Landolt's original determination for H, and also for C in saturated compounds. Gladstone points out that the hydrocarbons of the formula C.H. scarcely come up to Brithl's previous estimate of the higher value of C, so that in these cases he has adopted the figure 5.95 instead of 6.1, as the difference is more than he considers can be accounted for either by dispersion or by the distance from the boiling-points. In the case of those substances where the C atoms outnumber those of II, all of which show an inordinately high refraction and are at the same time enormously dispersive, Glaustone points out that Kanonnikoff's view that the increase is due to dispersion alone is not established by that observer's own figures for the theoretical limit of the spectrum according to Cauchy's formula. He admits, however, that if the limit were carried back considerably further, though still fairly within what Langley's observations would allow, the values would so far approximate as to render it not impossible that the refraction equivalent of C might prove to be the same in these compounds as in the benzenoid series, or wherever it is doubly linked. As to the halogens, the figures in the table are generally consistent with the values which were originally assigned by him to Cl, Br, and I, viz. 9.9, 15.8, and 24.5 respectively. These numbers are very nearly the same as those arrived at independently by Haagen, viz. 9.8, 15.3, and 24.8. The values for O are taken from Brühl's original determinations, though the evidence of the alcohols rather favours his old estimate of 2.9 for the line A.

With regard to the phenomena of dispersion, Gladstone points out 'that the double linking of carbon atoms, while it does not much affect the specific refraction, widens the spectrum greatly, to such an extent indeed that where there are three pairs of such carbon atoms the specific dispersion is about double that of a saturated compound; where, however, the carbon atoms are actually in excess the dispersion becomes far more rapid. This is evident throughout, but the following typical hydrocarbons may illustrate it:—

II		0.7000	a:	0.0040

'The effect of the halogens in lowering both the specific refraction and dispersion is very marked, and that of NO₂ is still more remarkable.'

Gladstone (C. J. 59, 290, 589) has since published other long series of observations; including a record of experiments on the effect of changes of temperature on the refraction of

some highly-refractive substances, which seem to confirm the opinion previously expressed by Dale and himself. Among the substances contained in these tables the benzyl and benzal camphors of Haller call for special notice, as they have a very high refraction, and a dispersion which is altogether excessive. The latter compound has in like manner a very high rotatory power. The hydracids in aqueous solution are shown to have not only a higher value than the normal, a fact which has long been observed, but also that the value rises with dilution; and that in the dispersion the excess is still more striking. The same fact was observed by Perkin in regard to the molecular magnetic rotation of these acids dissolved in water, both as to the initial excess, and to its increase with the dilution up to a certain point where it remained nearly constant.

Other investigators have availed themselves of the optical proporties is order to determine the constitution of compound bodies, or to emfirm the views arrived at on other grounds. Knops (A. 248, 175) has determined the indices of refraction of the methyl, ethyl, and propyl salts of fumaric, malcic, mesaconic, citraconic and itaconic acids. A comparison of these acids with their ethereal salts leads to the conclusion that fumaric and maleic acids contain only one dopbly-linked carbon atom; and that fumaric acid stands in the same relation to malcic acid as mesaconic acid does to citraconic acid.

Kanonnikoff (J. pr. [2] 31, 321, 497) has made a long series of observations on solutions of solids, of which he tabulates seventy-nine different substances, using water, alcohol, benzene, and chloroform as the solvents. As a preliminary inquiry, he reviewed the work of former investigators, and in some cases added experiments of his own to confirm previous conclusions: that the refractive energy of a substance is not changed in passing from the state of a liquid to that of a gas or vapour; that the same applies to bodies in passing from the solid to the liquid condition; that the refraction-equivalent of a mixture of liquids is the sum of the refraction-equivalents of its constituents; and that if the refraction-equivalent of a mixture and that of one of the components, together with the proportion of the same, is known, the refraction-equivalent of the other component can be calculated; that the same law applies to solutions of solid bodies, and that like results will be obtained whatever the solvent may be; that a derivative will be comparable with the substance from which it is derived, though the one may be a liquid and the other a solid body, as in the case of mesaconic acid and ethyl mesaconate. From the results of the observations above referred to, K. has determined the refraction equivalents of fourteen of the elements, as follows :-

Element	Ro	R_{∞}	Element	R_{σ}	R _{so}
Lithium	3·16 4·22 7·75 12·04 13·05 19·55	8·00 4·00 7·40 11·30 11·60 12·53 18·70	Magnesium . Calcium . Zinc . Strontium . Cadmium . Barium . Moreury .	7.03 9.32 9.80 11.61 13.03 15.84 19.20	6:47 9:05 9:40 11:25 12:66 15:28 17:90

K.'s values for the solar line C will be found to be generally slightly lower than those determined by Gladstone for the line A. The refraction-equivalents for the theoretical limit of the spectrum were also calculated by Cauchy's formula from observations of the lines α and β of hydrogen. K. also gave determinations of refraction-equivalents of thirty organic liquids, showing the excess due to the double linking of the carbon atoms wherever this occurred.

Nasini (Lincei, Rc. 1, 1) points out that the suggestion thrown out by Gladstone that there may be a third and higher value of carbon when its four bonds are satisfied by other carbon atoms, is supported qualitatively by the researches of Bernheimer and himself, but not quantitatively, and that, therefore, this hypothesis is not a sufficient explanation of the facts. He argues as follows: naphthalene derivatives have two such atoms, while cinnamic alcohol has but one, whereas the values differ but very little. Anethol with one such carbon atom has a much greater excess than the naphthalene derivatives, while styrol shows so slight an excess, that on this hypothesis it could hardly be allowed to have any carbon atom in this condition. He compares two pairs of isomeric bodies, both as to refraction and dispersion

Substance		R _a	$\frac{\mu_{\beta}-\mu_{\alpha}}{d}$
Allyl phenylate. Cinnamic alcohol	:	70·45 73·83	0·0173 0·0220
Allyl paracresolate Anethol	:	78·79 82·95	0·018 0·0257

from which he infers that when the allyl group is directly united to the benzene nucleus the molecular refraction greatly increases, whereas when the union takes place through the intervention of oxygen no augmentation takes place; so far, therefore, while supporting the hypothesis of Gladstone, he does not find any proportionality between the number of such carbon atoms and the increase of refraction.

Nasini (Lincei, Rc. 3, 164) criticises some of the conclusions of Brühl in the paper on the molecular refraction of organic liquids of high dispersive power (A. 235, 1) already referred to; and in particular he points out that the elimination of dispersion, if that were possible, would not get rid of the discrepancies between the observed and calculated values for the refraction of substances of high refractive power, and he cites 'observations on a series of substances in which he finds the constant fact that on adding a saturated side chain to an aromatic nucleus the specific dispersion diminishes while the refractive power increases.

Costa (G. 19) has made observations with the special object of testing the effect on dispersion of adding saturated side chains to a benzene or naphthalene nucleus. For this purpose he used compounds of amyl with benzene, thymol, eugenol, resorcin, and naphthol, and found in each case a still further increase in the refraction-equivalent than could be accounted for by the nucleus itself, while at the same time the specific dispersion showed a decrease.

Dispersion equivalents. In the same way that Gladstone arrived at the refraction-equivalents of the elements, he has sought also to determine the dispersion-equivalents of several of them; and (Pr. 42, 401) he has given the results of his observations upon nine of them, together with the values for the combinations CH2 and NO. The values are as follows:-

Su	bstar	100		R_{\blacktriangle}	Disp. Eqt. II-A

It will be observed that G. gives three dispersion equivalents for C, which he considers pretty well established, and he raises the question whether there may not be an intermediate refraction-equivalent corresponding to the dispersion-equivalent 0.51, which is found in such bodies as the allyl compounds and olefines. In his previous paper (Pr. 31, 327), G. suggested that there is a still higher refraction-equivalent of C in those cases in which it has four bonds satisfied by other C atoms, as in naphthalene and pyrene. Whatever may be the truth of this view, it appears that the dispersion-equivalents of these bodies are enormously high - much beyond what is recognised in the above table.

Brühl (Z. P. C. 7, 2, 140) has since modified his views upon the subject of dispersion; and has worked out carefully the atomic dispersions of some of the most important elements that enter into organic compounds. In the course of this investigation he has been led to revise his previous figures for the refraction as well as the dispersion. They now stand as follows: -

	Symbol	R.	R,-R.
Carbon, singly linked .	C'	2.365	0.039
Hydrogen	H	1.103	0.036
Oxygen (hydroxyl) .	0'	1.506	0.010
" (ether)	0; 0;;	1.655	0.012
" (carbonyl)	0"	2.328	0.086
Nitrogen, linked singly			
with C	N'	2.76	0.19
Chlorine	Cl	6.014	0.176
Bromine	Br	8.863	0.348
Iodine	I	13.808	0.774
Ethylene bond	-	1.836	0.23
Acetylene bond	=	2.22	0.19

It will be observed that B. retains Lorenz's formula; and that he takes the difference between the refraction of the hydrogen lines γ and α as his measure of dispersion. He now acknowledges that the molecular dispersion can be re-

garded and employed in like manner with the molecular refraction as a specific expression of the material composition of chemical bodies; and that the dispersion is decidedly more sensitive to structural influences than the refraction. His inquiries have convinced him that refraction and dispersion are in no general sense cor-relative properties; but that certain structural peculiarities that have much influence upon refraction have little upon dispersion, while others have the opposite effect, and, as a rule, exercise a much stronger Influence upon the dispersion. It is evident that this must be so, from the very high relative dispersion of O" as compared with that of O' or O<, and the large proportionate dispersion due to the ethylene bond. This figure, ·23, B. does not, however, recognise as a constant value. These revised values have since been used by him in his inquiries into the relations between the optical properties and chemical constitution of enchlorhydrin, the aldehydes and benzoyl (B. B. 24, 656), in which he draws attention to the concurrence of the evidence derived from chemical, calorimetrical, and optical investigations.

Essential oils. Gladstone (C. J. 17, 1; 25, 1) gave a long list of observations in which he recorded the circular polarisation as well as the index of refraction. The power of the oils in rotating the plane of polarisation appears to be very diverse, both in degree and direction; but he suggests that a comparison of the specific gravity and of the length of the spectrum may in some cases be of service in determining the genuineness or otherwise of the oils. The hydrocarbons obtained from these oils (of which a long table is given) divide themselves into two great groups, which are more fully investigated in the second paper.

Subsequently (C. J. 49, 609) the effect of the higher refraction and dispersion of C when united by double bonds was applied to the determination of the structure of the essential oils. Taking 2.2 as the increased refraction for the solar line A, and 0.8 as the increased dispersion, H-A, due to one pair of doubly-linked carbon atoms, the terpenes indicate, both by their refraction and dispersion, that they contain only one pair of carbon atoms doubly linked, thus corroborating the views of those who, on chemical grounds, have held that a terpene requires the addition of only two atoms of hydrogen, or their equivalent, to saturate it. The refraction and dispersion of solid inactive camphene also show that this substance does not contain more than one pair of doubly-linked carbon atoms, which is consistent with the fact that it combines with only one molecule of hydrochloric acid, and is directly converted by oxidation into camphor C₁₀H₁₅O, which is certainly a saturated compound both by c'emical and optical evidence. In the same way, the citrenes give a refraction and dispersion indicative of the presence of two pairs of doubly-linked carbon atoms. Allied to these are several hydrocarbons having different amounts of hydrogen, and the number of doubly-linked carbon atoms varying accordingly. Thus, while citrene C₁₀H₁₁ has two pairs, cymene O₁₄H₁₄, has three, while menthene C₁₀H₁₅ has but one pair of doubly-linked carbon atoms, and cymhydrene C₁₀H₂₀ has none, being

a saturated body. Pentene and isoprene C_sH_a are identical in their optical properties, and indicate that no less than four of the five carbon atoms are doubly linked, which accords with the fact that these compounds combine with four atoms of bromine or two molecules of hydrochloric acid. The following table will illustrate the foregoing conclusions:—

 μ_{L4} 2.408449 μ_{Na} 2.417024 and 2.417227 μ_{T1} 2.425487

These figures give R=4.8, a result slightly lower than his earlier observations on the diamond, in which the index for the red part of the spectrum is recorded as 2.434, and the S.G. 3.55. Selenion. Sirks (P, 143, 429) made

The advance in these experimental figures with the double linking is evident, though it is obscured in the first two cases by the larger amount of hydrogen contained in cymhydrene and menthene. The influence of the double linking upon the specific dispersive energy is apparent at a glance, and renders this property more valuable than the refractive energy in determining the rational constitution; though, of course, it is in the agreement of the two that the most conclusive evidence must be sought.

Kanonnikoff (Bl. [2] 36, 557) had already pointed out the differences between the calculated and observed refraction equivalents for the following substances:—

Substance	R_{∞}	Calcu- lated	Differ- ence
Peppermint camphor .	77.6	77:1	+ 0.5
Cajeputene hydrate .	74.8	74.5	+ 0.3
Terebenthene hydrate, lævogyrate	77.1	74.5	+ 2.6
French terebenthene, lævogyrate	71.7	69.2	+ 2.5
Hydrocarbon from oleum camillæ.	71.9	69.2	+ 2.7
Hydrocarbon from oleum thymiani .	71.4	69.2	+ 2.2
Isoterebenthene	73·6 74·8	69·2 69·4	+4·4 +5·4
Cymene from camphor .	72.0	66.6	+5.4

K. has drawn the conclusion that the first two contain no double bond, that the two terebenthenes and the two hydrocarbons contain one double bond, that isoterebenthene contains two, and that carvol and cymene contain three, double bonds.

Carbon. Schrauf (W. 22, 424) made observations on the refraction of a Brazilian diamond of the first water, the S.G. of which was 8.516, with the following results:

observations on the refraction and dispersion of solid Se. By pressing a small quantity of melted Se between two glass plates, he prepared a thin film of the substance, which exhibited Newton's interference bands. From these he was able to calculate the index of refraction for the solar lines A_a , B and C_a , with an estimated error not exceeding 0.003; and for D_a , with some difficulty and uncertainty, to the second place of decimals only. The values obtained were:— μ_A 2.654, μ_a 2.692, μ_a 2.730, μ_c 2.737, μ_D 2.98. From these S. calculated the dispersion as compared with water, calespar, and CS_a, the figures in each case being reduced to the standard of μ_0 — μ_A =100;—

Water 36 31	83	
		88
Calcspar 36 30 Disulphide of	34	90
carbon 34 31 Selenion 29 30	35 °	99 146

Comparing Se with CS, he found that while in the case of CS₂ $\mu_D - \mu_O$ differed very slightly from $\mu_O - \mu_A$, in the case of Se $\frac{\mu_D - \mu_O}{\mu_O} = 1.46$.

In testing Cauchy's and Christofle's formulæ for the index of the ray of infinite wave-length by the above observations, the former gave 2.733 and the latter 2.433. It will be observed that Cauchy's co-efficient of refraction is somewhat higher than the observed value for the solar line \mathbf{n} , which is 2.730, the co-efficient of dispersion in this particular case being a minus quantity.

Phosphorus. Gladstone and Dale (P. M. 1859) measured the index of refraction of both solid and liquid P. an elementremarkable not only for its very high refractive power, but for an unprecedented amount of dispersion. For solid Pat 25° they obtained for u. 2 1059, for u. 2 1442, and for the extreme limit visible in the violation.

fortion of the spectrum 2-3097. Assuming the latter to be equivalent to $\mu_{\rm H}$, the length of the spectrum $\mu_{\rm H}$ — $\mu_{\rm A}$ = 0-2038. For liquid P at 35° they obtained the following:—

μ	μ_{D} μ_{F} μ_{G}		μ _G	End of violet
2.0389	2.0746	2·1201	2.1710	2.2267

The change from the solid to the liquid state is attended with a considerable diminution of density, the ratio between the density and the refraction being about the same in the two conditions. The B_A of P is taken at 18:3 from the above observations on liquid P, but Gladstone points out (C. J. 23, 101) that when combined with O it seems to have a much smaller refraction, HPO_a giving a less value (18:0) than the P it contains, while H_APO₄ also has a refractionequivalent of only 23:6.

Sulphur. It was pointed out by Gladstone in 1869 (T. 159, 9) that while S, whether solid or liquid, has a refraction-equivalent of 160 or 163 for the solar line A, the equivalent for S deduced from CS_2 was 15.85; that the difference between KCN and KCNS gave a value of 16.24, and that S_2Cl_2 gave a similar figure. On the other hand, however, it was evident that in the two gases $H_2S = 14.28$, and $SO_2 = 14.91$, or in liquefied $SO_2 = 14.59$, the refraction-equivalent of S cannot amount to 160, nor yet in H_2SO_4 , which has a refraction-equivalent of only 21.9.

Wiedemann and Nasini have subsequently given considerable attention to the values of S in combination. Wiedemann (W. 17, 577) investigated the sulphur substitution products of the carbonic esters, and obtained the following results:—

influences, in a very distinct manner, the value of the index of refraction. From the refraction-equivalents given above W. obtains the value 14.04 for 8' in the compounds II. and III.; and for S'' 15.20, 16.31, and 17.45 respectively. Using Lorenz's formula he gets the value of 7.94 for 8', and 9.09, 9.44, and 9.38 for S''. Whichever formula be adopted, the figures show that the atomic refraction of S, like that of O, is greater when S is doubly linked to an atom of carbon. It should be observed that the above results are based upon the recognised values of O, H, O', and O'', which give

$$CO_{OC_2H_3}^{OC_2H_3} = R_{\infty}$$
 45.91, and R_{∞} 27.76;

and also that W. takes as the value of S' the mean derived from the observations II. and III. If Wiedemann had adopted a direct comparison of the actal observations, the values of S' would approximate more closely according to the old formula, and less closely according to Lorenz's formula.

Nasini (G. 13, 296; Lincei, Rc. 1, 1) has determined the value for S in various compounds. From sundry organic sulphides and mercaptans he obtained the atomic refraction of S corresponding to alcoholic oxygen. From CS₂, and from the compound CS(OC,II₂)₂, he deduced the refraction of S corresponding to aldehydic oxygen:—

Sulphur	Ra	R_{∞}	Ra	R _∞
	14-10	13.53	7.87	7.65
S" (doubly linked) .	16.05	15.09	9.02	8.84

		đ	μ1.1	μ _{Na}	μ	R_{∞}	R _∞
I.	COOC'H'	0.975	1.3837	1.3858	1.3876	45-66	27:80
II.	co ^{OC} ,H,	1.0285	1.4479	1.4515	1.4544	56-95	84-11
III.	COSC,H,	1.085	1.5168	1.5237	1.5287	69-15	40.57
IV.	CSOC,H,	1.0325 ?	1:4563	1.4601	1.4632	57.82	84.56
٧.	CS SC,H	1.085	1.5301	1.5370	1.5431	70-26	41.28
VI.	CS SC,H,	1.152	1.6105	1.6210	.—	82.73	47.56

From these figures it will be seen (1) that the index of refraction rises whenever an atom of O is replaced by an atom of S, and that so much the more, the more S there is already in the compound; (2) that the refractive indices of the combinations which contain the radicle CS are greater than those of their analogues containing OO; (3) that the refractive index likewise increases if, besides the radicle, first one and then a second atom of S replaces O, and in the latter case more than in the former; (4) the isomeric bodies II. and IV., as well as III. and V., have quite different indices of refraction, and in both cases the compound that has the S in the radicle has the higher index. This indicates that the mosition of the S in the compound

But when examining other compounds, such as H_xSO_t , SO_x , and SO_x . N. found that whatever hypothesis he adopted as to their constitution—or, in other terms, whatever value he took for the atomic refraction of O—he obtained values for S, not very discordant among themselves, but totally different from those given above. Treating the sulphur as divalent, R_∞ varied from 8:10 to 9:01; as tetravalent, from 6:94 to 6:43; as hexavalent, from 6:63 to 7:85. Calculating by Lorenz's formula, R_∞ ranged from 5:24 to 6:27 in the first case, from 4:51 to 4:91 in the second, and from 8:13 to 8:79 in the third. Some observations recorded by Kanonnikoff (J. R. 15, 434) substantially support these figures.

Nasini and Scala (Lincei, Rc. 1886. 617, 623) record observations on the sulphocyanides, which show that the mustard-oil compounds have refractive and dispersive powers in excess of those of their isomerides, while phenylic isosulphocyanide has a specific refraction and dispersion far above the calculated values-exceeding, in fact, oil of cassia or CS₂. In this combination the union of the group S=C=N, endowed with a high refractive power, with the phenylic group, also highly refractive, appears to produce a heightening of the refrangibility, a phenomenon which N. regards as analogous to the increase in refraction which he observed when in the benzene group an unsaturated side chain is ioined to an unsaturated carbon atom. In compounds containing four atoms of S there is an excess of refraction above what is estimated from the value of S in CS, the monothiocarbonates of Et and Pr giving a value of 17.4 and 17.5 for the refraction-equivalent of sulphur.

Nasini a. Costa (Ist. Ch. Rome, 1891) made

lished (Ar. N. 8) a long series of very careful determinations of the indices of refraction of mixtures of H.SO, and H.O, in various proportions for all the principal lines of the solar spectrum from A to H inclusive. These show a progressive increase in refraction and dispersion with every addition of H2SO4, until a maximum is reached at a point corresponding, apparently, with the monohydrate of the acid. after passing which the refraction and dispersion suddenly decline, while the density of the mixture continues to increase. Out of the seventeen series of determinations at different concentrations, the seven most conc. are given below, the central one of the series representing the nearest approach to the maximum. The indices are all reduced to a temperature of 18.3°. The specific gravity given in the line below is for 0°, water at the same temperature being taken as 1.0. In the cases of the two G's and the two II's, the higher one in each corresponds with the lines so designated by Fraunhofer.

further studies of S and its compounds. They conclude that the oxygen compounds, which are generally distinguished by a low refractive and dispersive power as compared with those not oxygenated, may be divided into two principal groups: those which may be regarded as derived from SO, have the higher, and those derived from SO, have the lower, refractive and dispersive powers. Kanonnikoff (S. Ph. Ch. Russ. 16, 129) assumed that the refraction of S varies with the change of valency, and assigned the following values for R_a:—

S divalent 14:10 S tetravalent 8:72 (in sulphones) S hexavalent 4:85 (in H₂SO₄)

but this is not accepted by N. and C. They find that the accumulation of S in the molecule is almost always accompanied by an increase in the refractive and dispersive power. In this respect, though not in others, S appears to have much analogy with carbon. Throughout this investigation N. and C. tested the dispersion formula of Ketteler, $\frac{\mu_a^*-1}{\mu_b^*-1}$, in which a and b represent rays of different wave-length, and found that it gave very uniform results; but from a physico-chemical point of view they do not regard this fact as an argument in favour of the formuls.

Sulphuric acid. Van der Willigen pub-

Van der Willigen pointed out that the formula $(100-p)\frac{n^2-1}{d}+p\frac{n'^2-1}{d'}=100\frac{n''^2-1}{d'}$ will not apply to mixtures of $H_2\mathrm{SO}_4$ and water, where 100-p and p are the respective weights of the two mixed liquids, n, n', and n'' the indices of refraction, and d, d', d'' the densities of the two liquids and the mixture respectively. Dale and Gladstone had formerly stated that the same was the ease in respect of their formula.

Nickel and iron carbonyls. Mond has prepared Ni(CO), and Fe(CO), both liquids of a highly-refractive character. former has been examined optically by Nasini (Lincei, Rc. 7, 411), and the latter by Gladstone. Ra for the nickel compound was found to be as high as 57.7, which, deducting 8.4 for the value of each CO, gives Ra = 24.1 for the metal itself, instead of about 10.0, as determined from the chloride, sulphate, and nitrate. This would seem to confirm the hypothesis that the refractive power varies with change of valency, increasing with the increased power of combination. In this compound the Ni is regarded by Mond a. Nasini as octovalent, and as justifying Men-deléeff in placing it in Group VIII. of his system of classification. Gladstone, on the other hand, is disposed to think that the metal in both compounds is, as usual, divalent, and that it is the

60 which has a greatly increased value. He obtained for Fe(CO), $R_{\rm h} = 67.33$, $R_{\rm p} = 69.40$. These figures show not only a very high refraction, but also very great dispersive power.

Silver iodide, bromide, and chloride.

Silver iodide, bromide, and chloride. Wernicke (A. 142. 560) measured the refraction and dispersion of light by these salts in two different ways: (1) by examining the light reflected from glass plates covered with a layer of these salts, by means of a spectroscope, and noting the position of the dark interference-bands; (2) by direct measurements of small prisms made of the fused salts. The portion of the spectrum observed ranged from the solar line C to G. The dispersion \(\mu_{\text{O}-\text{W}} - \mu_{\text{D}} \) was about twenty-seven times that of water in the case of the iodide; that of the other two salts is much less, though considerably greater than that of fint glass. AgI seems capable of existing in two conditions: at temperatures above 138° it gives a short spectrum limited to the red, yellow, and green, while below that temperature it gives a spectrum twice as long, showing all the colours. W. believes that AgI is partly dissociated at the higher temperatures.

ciated at the higher temperatures.

Bromino. Weegmann (Diss. Bonn, 1888) determined the refraction-equivalent of Br by Lornz's, as well as by the older, formula, for both the hydrogen lines, a, and Cauchy's limit, from a series of ethylene and acetylene compounds, adopting Brühl's values for C, II, and the ethylene linking. The following are his figures for Br compared with those arrived at by Brühl:—

Bromino	Rx	R.	R _∞	R.
Weegmann .	14·78	15·38	8·56	8·83
Brühl	14·81	15·39	8·70	8·95

Fluorine. The writer of this article has collated the observations made by various observers on bodies containing. F in order to arrive at the refraction-equivalent of this element (P. M. 1885, 481). Those of Brewster on cryolite, of Brewster, Wollaston, Fizeau, Stefan, and Kohlrausch on fluorspar, and of Gladstone on aqueous solutions of KF, give a refractionequivalent for F varying from 0.29 to 0.32. Those of Topsöe and Christiansen on crystalline silicofluorides of Cu, Ni, Zn, Mg, and Mn, of the formula RSiF, 6H,O, give a refractionequivalent for F varying from 0.62 to 0.84; while (NH.), SiF. gives 0.59 for F. The latter figures must be accepted with caution, as a very slight difference in the values ascribed to the other elements will account for the whole of the discrepancy. It is evident, however, that in any case the refraction-equivalent is of exceedingly small amount, and that the specific refraction, even if the highest value be taken, can scarcely be the half of that of any other element known.

J. H. and G. Gladstone (P. M. 1891. 1) have investigated the optical properties of fluorbenzene and allied compounds. The molecular refraction for C_bH_cF, for six lines of the solar spectrum, is given in the following table; from this is deducted the value for benzene less one atom of H, leaving a small balance as the atomic refraction of fluorine.

These figures are remarkable as giving a negative value for the dispersion R_B-B_A namely the

	R	R _a	R	R	Ro	RH
C.H.F C.H.	42·92 42·29	43·33 42·70	43·70 43·17	44.68 44.20	45·61 45·17	46·40 46·05
F	0.63	0.63	0.53	0.48	0.44	0.85

quantity, -0.28. According to Lorenz's formula $\mathbf{R}'_{\mathbf{A}} = 0.92$ and $\mathbf{R}'_{\mathbf{R}} = 0.84$, showing in like manner a negative dispersion. The observations of Baille, Stefan, and Sarasin on fluorspar, and those of the authors on solutions of KF and NII, F, all distinctly confirm the foregoing evidence as to the anomalous dispersion; while a comparison of the refraction of the three lines C, D, and F of the solid silicofluorides measured by Topsöe and Christiansen, and the author's observations on aqueous solutions of $\mathbf{H}_{\mathbf{Z}}\mathbf{SIF}_{\mathbf{z}}$, seem to point in the same direction.

Liquefied gases. Bleckrode (Pr. 87, 889) adopted a special apparatus for measuring the indices of refraction of liquefied gases, consisting of a modification of a Faraday tube, forming a vessel having two parallel side plates, free from leakage even at high pressures. By observing, through a microscope provided with a graduated scale and a micrometer screw, test objects, such as lepidoptera scales, attached to the inner surface of the glass plates of the cell, the variation in the focus between the direct observation and that through the cell and liquid was found, and, with a correction for the effect of the glass, he obtained the data from which to calculate the index of refraction according to D

the equation $\frac{D}{D-d} = \mu$, in which D represents the thickness of the layer of liquid and d the apparent displacement of the test object. The observations were taken both with a sodium flame and with daylight, and the calculated probable error of the result amounted to \pm 0-003. The first table on p. 218 gives the results of B.'s observations compared with those of Dulong, Ketteler, Croullebois, and Lorenz on the same substances in the gaseous state; the specific refraction is calculated by both the formulæ in common use.

B. drew attention to the remarkably low S.G. of cthylene, as the lightest fluid substance known; his determinations gave 0.335 at 8°, 0.361 at 6°, and 0.386 at 3°. B. also gave determinations of the indices of refraction of the following substances taken by the same process; and commented on the high indices of the organo-metallic compounds as inconsistent with the opinion expressed by early observers that a high index of refraction is indicative of a body being combustible.

Alums. The indices of refraction of some of the alums have been measured by several observers, amongst them Grailich, Fock, Kohlrausch, Stefan, Topsöe, and Christiansen. The most complete series of observations on inorganic sulphuric alums is that of Soret (Ar. Sc. Geneve, 12, 553; 14, 96; 20, 517), including those containing Rb, Cs, In and Ga. His mode of determination was by total reflection, which he considered the best adapted for the purpose; he gave indices which he calculated to be correct to two units in the fourth place of decimals. His observations were given for eight rays of the solar spectrum, viz. the lines a, B, C, D, E, b, F and G. He remarked on the very low value of the index of refraction of the Na-Al alum. He gave the following comparative table for $\mu_{\rm D}$, showing that the different series of alums vary in general with much regularity. The horizontal lines contain the same metal, and the vertical lines the same metal or alkaline radicle.

	NH.	K	Rb	Cs	Ti
Aluminium Indium Gallium Chromium	1:4594 1:4664 1:4683 1:4842 1:4848	1.4564 1.4658 1.4814 1.4817	1·4566 1·4638 1·4658 1·4815 1·4823	1:4586 1:4652 1:4649 1:4810 1:4838	1·4975 1·5066 1·5228 1·5236

Calculating for each salt the difference between its $\mu_{\rm D}$ and that of the ammoniacal alum on the same horizontal line, Soret obtained:—

	NH ₄ -K.	NH ₄ -Rb	NH ₄ -Cs	NH ₄ -Tl
Aluminium Indium Gallium Chromium Iron	+0.0080 0.0080 0.0028 0.0081	+0.0028 0.0026 0.0025 0.0027 0.0025	+0.0008 0.0012 0.0034 0.0082 0.0010	-0.0381 0.0383 0.0386 0.0388

These figures show a close accord, except in the case of Cs, in which the Gs and Cr compounds

appear to be too low. Soret did not consider that the impurity in the specimens, if any existed, could be due to the Ca.

could be due to the Cs.

Gladstone (P. M. 1885. 162) worked out the refraction-equivalents from the data given in the first named of Soret's papers, and also from those by Topsõe and Christiansen, in order to test his former conclusions that a salt has the same specific refraction whether it is in a solid form or in solution, and that the refraction-equivalent of a compound body is the sum of the refraction-equivalents of its constituents. As to the first point, in the case of the two alums given below he found the specific refractions, after deducting the amount due to the solvent, to be in substantial accord:

Dissolved Crystallised Ammonium-aluminium alum 0.2780 Sodium-aluminium alum . 0.2613 To test the second point, the alums were regarded as compounds of the sulphates of two metals of different kinds with twenty-four molecules of water. Taking the RA of water in the uncombined state at 5.926—and taking the observations of Kanonnikoff, Topsöe, and Christiansen, as well as his own, of the several sulphates-Gladstone arrived at the results given in the following table. The other observers did not take the A line, but their observations have been reduced to A for purposes of comparison. The agreement between the calculated and observed refraction-equivalents is as near as might be expected, except in the case of Cs.

		RA observed and reduced		
Substan ce	R _A calcu- lated	Boret	Topsöe and Christiansen	
Ammonium-aluminium alum Sodium " " " " " " " " " " " " " " " " " " "	252-0 239-8 267-2 345-1 254-0 268-0 257-1 266-0 280-0 370-6 263-7 273-6 286-6	252·2 238·5 267·7 246·8 253·7 265·9 261·2 266·7 275·5 269·1 265·0 278·2 278·0	268-6	

Gladstone also sought, by means of Soret's observations, to determine the refraction-equivalents of In and Ga, and (B. A. 1892) he gave the following constants:—

				At. W.	RA
Indium Gallium	:	:	:	113·4 69·9	13·7 11·6

These figures, however, can only be looked upon as approximate, as all experimental errors are accumulated on these residual numbers.

Perrot (Ar. Sc. Genève, 1880) has made a series of observations on the refraction and dispersion of an isomorphous series of biaxial orystals -the double sulphates of Zn with K., Rb₂, (NH₄)₂, Cs₂, K₂, and of Mg with Rb₂, and in each case 6H₂O. He has followed the plan adopted by Soret in his observations on the alums. The results conform satisfactorily to the values computed on the same principle as that adopted by Gladstone with respect to the alums, except in the case of casium and rubidium, in both of which, especially the former, the observed values are lower than the theoretical. The mean ray adopted for this calculation is, however, the arithmetical mean of the three indices observed for each of the lines of the spectrum, and has, therefore, no real physical significance. A glance at the tables of observations will show at once what a wide scope for error there is in arriving at a mean value by this process.

Analogy between refraction and dispersion and magnetic rotation. Gladstone and Perkin have recently observed an analogy between the magnetic rotation and the refraction and dis-persion of light. They have tested this in the case of organic compounds containing nitrogen (C. J. 55, 750), with the result that they have found a correspondence that points to some connection between the rotation of the polarised ray under magnetic influence and the retardation of the rays of light in passing through a material substance. These three properties are really comparable with one another, for in each case the observed value is divided by the density of the substance, and it is determined, not for equal weights, but for an equal number of molecules. It has been found that each property is determined in the first instance by the atomic composition of the substance, so that it may be laid down as a primary law that the molecular magnetic rotation, like the molecular refraction or dispersion. of a compound is the sum of the molecular magnetic rotation, refraction, or dispersion of its constituents. The values are, however, subject to large modifications dependent upon differences in the structures of the compounds. Thus a change of valency-is attended by a marked change of value in these optical properties, and they are apparently affected by some circum-stances which are not as yet recognised in structural formulæ.

The following values have been deduced by Perkin for the molecular magnetic rotations of certain elements in the paraffin group of carbon compounds; and against them are placed the recognised values for their molecular refraction and dispersion:—

	Molecular mag- netic rotation	R_{A}	R _{H-A}		
CH	1.023	7.6	0.34		
c	0.515	5.0	0.26		
H	0.254	1.3	0.04		
O, alcoholic .	0.194	2.8	0.10		
O, aldehydic.	0.261	3.4	0.18		
ci	• 1.733	9.9	0.50		
Br	3.562	15.3	1.22		
Ι	7.757	24.5	2.62		
N, in amines	0.717	5.1	0.88		
· .					

These figures show a certain analogy; and when modifications are introduced by changes in the mode of combination, the change that occurs in the one property is noticeable also in the other two, and that in the same direction, though not necessarily to the same extent. Thus there are in all cases two different values for oxygen in alcohol and aldehydes, and a very great increase of the values in the case of unsaturated carbon compounds. The values also of CH, in the first and second members of homologous series (such as the alcohols, parallinoid acids, &c.) are different from its value in the higher members of the same series, and always in the same direction.

P. also applied the same inquiry to solutions of HCl, HBr, and HI, which when dissolved in water were known to give higher values for refraction and dispersion than the normal. The same was found to be the case in the magnetic rotations. When HCl was dissolved in isoamyloxide, however, all three values were found closely approximating to the normal, as will be seen in the following table:—

Hydrochloric acid	Molecular magnetic rotation	$\mathbf{R}_{\blacktriangle}$	R _{H-A}
In water , isoamyloxide .	4·412 2·238	14·45 11·36	1·12 0·51
By calculation for free acid	2·187	11.20	0.54

It is, therefore, laid down as generally, if not always, true, that where there is a departure from the normal values in regard to one or other two. The different properties are evidently similarly affected by change in chemical constitution. The investigation seems to indicate another close relationship between electro-magnetism and the velocity of light. G. G.

OPTICAL METHODS.—Section 2: SPEC. TROSCOPIC METHODS.

Historical notes.—Spectrum analysis is an optical method of making a diagnosis of the chemical composition, and in certain cases the chemical constitution, of either (a) a self-luminous body, or (b) an absorbing medium, whether self-luminous or not. Newton first discovered that light could be analysed when passed through a prism, and, in 1752, Thomas Melvill made an optical analysis of alcohol fiames coloured with

salt and with nitre. Wollaston, in 1802, observed with the prism certain obscure bands in the solar light which had traversed a narrow slit in his window shutter. Fraunhofer, in 1814-15, was the first to employ a very narrow and accuratelyformed aperture with a prism, telescope, and divided circles, and he not only observed the dark lines in the solar spectrum, but measured their indices of refraction or refrangibilities. He examined, subsequently, the spectra of the stars, of electric light, and of the exterior envelope of the flame of a wax candle. 'The latter spectrum he discovered to consist of homogeneous yellow light, composed of two distinct rays very close together, and coincident with the two dark lines in the solar light which he had termed D. Brewster floted the presence of this yellow light in the combustion of many substances, but it was Box Talbot who, in 1826, clearly proved that the source of this light was sodium. He likewise connected a red ray with the presence of potassium and an orange ray with strontium, and concluded that a glance at the prismatic spectrum of a flame may show it to contain substances which it would otherwise require a laborious chemical analysis to detect. Herschel had previously described the spectra of a few of the metals and of boracic acid. In 1834 Fox Talbot described the strontia and lithia spectra, and stated that optical analysis could distinguish the most minute portions of these two substances with as much, if not greater, certainty than was afforded by any other known method.

Wheatstone, nearly at the same time, published some experiments similar to those of Fox Talbot, and Swan first estimated the amount of sodium which can produce the D lines. At the Manchester meeting of the British Association in 1842, Brewster read a paper On Luminous Lines in Certain Flames corresponding to the defective Lines in the Sun's Light. He discovered the dark lines of absorption in nitrogen peroxide gas when white light is directed through it, and he observed and mapped a number of atmospheric lines in the solar spectrum. In 1849 Foucault obtained a reversal of the D lines in the electric arc. Stokes, about 1850, gave in his lectures the true explanation of the coincidence of sodium lines with the dark lines D. Angström in 1853 stated that an incandescent gas emits luminous rays of the same refrangibility as those which it absorbs, and Balfour Stewart, 1858-9, based the following statement on experimental data: The radiating power of a body for any ray is equal to its absorbing power for the same ray.
In 1859, Kirchhoff and Bunsen gave a great

In 1859, Kirchhoff and Bunsen gave a great impetus to spectrum analysis by publishing their researches on the constitution of the sun, and also by designing an extremely simple spectroscope and describing its use. Chemists were further made aware of the new power placed in their hands by Bunsen's discovery of two new metals, rubidium and cessium, in 1860, by the discovery of thallium by Crookes and by Lamy in 1862, of indium by Reich and Richter in 1863, and of gallium by Lecoca de Boisbaudran in 1875.

and of gallium by Lecocq de Boisbaudran in 1875.

Fundamental laws. Spectrum analysis primarily depends on the following two laws:

1. Every solid and liquid when heated begins by emitting rays of longest wave-length, which are

the result of comparatively slow vibrations, but as the temperature rises the vibrations become more rapid, and shorter waves are emitted, so that at the highest temperatures the sum of the radiations is white light, consisting of waves of all possible lengths, the effect of which is a continuous spectrum. A mass of iron gradually raised to its melting-point would be an example of this. 2. Every substance vapourised by heat emits rays of definite wave-lengths, and these rays are characteristic of each substance, because it alone can emit them. In other words, every substance vapourised by heat has its own definite periods of vibration, by which it can be absolutely identified, because no other substance can vibrate in the same manner and with the same periods. All flame and spark spectra furnish examples. From this second law it follows that the spectrum of an element is a constant of very great importance. The determinations of the spectra and of the atomic weights present similar diffi-culties, which arise from the necessity for obtaining the elements or their compounds in the highest possible degree of purity, and also in many cases from the complexity of the spectra, and the careful observations which are necessary in identifying and measuring the wave-lengths of the rays.

Determinations of the absolute wave lengths of the bright lines in any spectrum are now usually made either with a plane or a concave diffraction grating ruled on speculum metal. When a sufficient number of accurately-measured lines is known for any region of the spectrum, determinations of the wave-lengths of lines in new spectra may be made by observing with a prism-spectroscope, and by the use of an interpolation curve the wave-lengths corresponding to the positions of the lines measured may be found. From time to time the curve will require verifying and correcting.

There are two classes of spectra, emission and absorption spectra.

Emission spectra consist of: (1) Continuous spectra and (2) Interrupted spectra. 1. Continuous spectra are characteristic of most incandescent solids, liquids, and gases at great pressures, or of a cloud consisting of solid glowing particles. 2. Interrupted spectra consist of: (a) Bands of light or 'fluted band' spectra, characteristic of certain vapours, especially the vapours of compound substances rendered glowing at comparatively low temperatures; (b) bright line spectra, characteristic ohiefly of transparent vapours at high temperatures or at low pressures; (c) reversed line spectra, which are dark lines segn on a brilliantly-illuminated ground. When a bright line spectrum is observed in front of a more brilliant continuous spectrum, the lines appear dark on a bright ground of colour, instead of bright and coloured on a dark ground, and they are then said to be reversed.

Absorption spectra. When rays capable of giving a continuous spectrum are made to traverse (ag transparent solids, (b) transparent liquids, (c) transparent gases at ordinary temperatures, it is frequently observed that a definite band of rays is absorbed at either end of the spectrum. This is called a continuous absorption. Quite as frequently a band of rays is out out of the middle of the spectrum; this is called a

selective absorption, and the region of the rays absorbed is said to be occupied by an absorption band.

The production of emission spectra. Emission spectra may be produced in the following ways (a) By flames of low temperature, e.g. by a spirit lamp or Bunsen burner, acting on solids, or the spray of solutions. The flame may be fed with chlorine, bromine, or iodine, or with hydroshlorine acid when salts of the halogens are examined. (b) By flames of high temperature: blow-pipe, and oxyhydrogen flame. (c) By sparks in vacuum tubes containing residual gases or vapours. (d) By sparks of low tension acting on solids or solutions. (e) By sparks of high tension. (f) By solids in the electric arc. (g) By electric discharge on solids in vacuo; these are phosphorescence spectra.

As a rule, line spectra are the spectra of elements, band spectra are the spectra of compounds.

Salts of the alkali metals in the Bunsen flame emit line spectra characteristic of the metals, while the alkaline earth salts emit lines and bands which are characteristic of the metallic oxides. On the other hand, the burning of hydrogen and of hydrogen compounds causes the emission of more than 160 lines in the ultraviolet region, which can only be assigned to the vapour of water at a high temperature. Carbon is an element which emits bands in the coloured region, in hydrocarbon flames. A list of compounds which emit characteristic banded flamespectra is given on p. 246. Erbia and erbium phosphate emit luminous bands when the solid substances are heated in a Bunsen or blow-pipe flame. Discharges in vacuum tubes sometimes emit a continuous spectrum; oxygen does so at the lowest temperature at which it is luminous. Most gases emit a banded spectrum with low tension sparks at ordinary pressures; The spectrum alters with diminution of pressure until finally nothing but a line spectrum is visible - for example, this is the case with air in the ultraviolet region. Sparks of low tension from solids, such as metallic electrodes, and from solutions, emit lines chiefly in the visible region, while those of high tension are generally richest in radiations of high refrangibility, chiefly in the ultra-violet region.

Low-tension sparks may be produced in two ways from solutions, first by wires of platinum moistened by the liquid, secondly by pieces of charcoal giving the flaming spark used by Bunsen. Many elements have been shown to emit a few bands or lines in the infra-red. The difference in action of high- and low- tension sparks is chiefly, if not entirely, due to temperature; the highest temperatures cause the emission of rays of the highest refrangibility. Solid elements, with few exceptions, yield spectra in the electric arc. The lines exhibited by some of the metals are exceedingly numerous. Reversed line spectra are common in the sun, and afford evidence of the presence of metals whose bright line spectra are coincident therewith. number of bright lines seen reversed in the sun's spectrum indicates the strength of the evidence of the existence in the sun of certain elements.

As to the distribution of known kinds of Vol. IV.

matter in space, the following list shows the elements observed in the sun with the numbers of their reversed lines seen in the solar spec trum: Fe 730, Ti 230, Ca 94, Mn 85, Ni 102, Co 91, Cr 71, Ba 26, Na 11, Mg 17, Cu 7, H 5, Pd 5, V 4, Mo 4, Sr 4, Pb 3, U 3, Al 18, Ce 2, Cd 2, Be 2, Sn 1.

Methods of spectrum analysis. For efficient work with the spectroscope an instrument is to be preferred which admits plenty of light, has a rigid collimator, and immovable prism. Compound prisms of Grubb's and of Thollon's construction are among the best. The arc should be divided on the vertical edge of the prismtable or on an edge inclined at an angle of 45%. A vernier travelling over the are and a mounted lens, for convenience in reading the scale and vernier, should be fitted ficar the telescope. A beautiful instrument made by the Societé Génevoise pour la Construction des Instruments de Physique has a circle completely divided, and titings for investigating ultra-violet spectra, either by photography or with a fluorescent eyepiece of Soret's design. It is provided with two verniers, and an automatic arrangement admitting of the prism being placed at the minimum angle of deviation for each ray under examination. This is necessary in order to secure the best definition. The instrument, of whatever form. should be capable of dividing and measuring the lines D1 and D2 of sodium, the first, second, and third lines of the yellow band; and in the carbon spectrum the first, second, third, and fourth lines of the green band, and the first, second, and third lines of the blue band, which are seen in the green inner cone of a powerful Bunsen burner. An instrument with a photographic scale, if it is sufficiently delicate, which is seldom the case, is of great use. One of these, constructed by Duboscq, was employed by Lecocq de Boisbaudran. A lens of short focus should be used to concentrate the light, from whatever source, upon the slit of the instrument. A test tube about 12 mm. diam., supported vertically, if filled with water and placed close to the slit of the instrument. answers this purpose. The telescope should be capable of easy movement without vibration, and be supported for two-thirds of its length from the object glass; neither clamping nor the use of the focussing screw should be capable of displacing its position. The rays should pass straight down the collimator and completely fill the lens. Before commencing any serious work. the capabilities of the instrument and its use for obtaining measurements should be carefully studied.

Supports of platinum wire fused into glass tubes are used for examining concentrated solutions and fused beads of salts in ordinary flames. Bunsen burners with steatite tops are particularly useful. Blow-pipe flames with a vertical direction, urged by bellows worked by the food are useful for examining the alkaline earths. Hydrogen gas from a constant generator made of lead and of large size is better than coal-gas or hydrogen be used, it is advantageous in examining salts of the alkaline earths, particularly chlorides, to pass the gas through a litre of strongest hydrochloric acid into a Bunsen burner, which is made of hard glass tube tipped

with platinum. The flame is thus supplied with hydrochloric scid, and the chlorides are volatilised apparently without decomposition, so that they emit rays of great brilliancy which yield simple line spectra. For high temperatures a very small gas blowpipe may be supplied with oxy-In this case the supports of platinum would be fused, and it has therefore been found convenient to use a wire of iridium, twisted into a loop, the compound being placed in the loop. In this manner manganese dioxide yields the bands of the dioxide, the spectrum of which is observed in the Bessemer flame. Calcium fluoride and copper oxide readily yield characteristic spectra. The alkaline earths yield very brilliant spectra, which are due to the metallic oxide in each case. When volatile substances, such as salts of lithium and the other alkalis, are under observation, it frequently happens that a difficulty in measuring their lines occurs owing to the evanescent appearance of their spectra; more lasting spectra may be produced by converting the volatile salts into silicates or borates by heating in a platinum spoon, or even in a porcelain crucible, with crystals of boracic acid. Beads of the borates will continue to illumine a flame for a lengthened period; with lithium and thallium, measurements have been made for as long as twenty minutes without renewing the material. Should the alkalis be accompanied by lime, strontia, or baryta, the spectra of these earths are suppressed, but towards the end of the observation sometimes the green colour of boric oxide appears. Sparks, both of low and high tension, may be used with Delachanel and Mormet's fulgurator. This instrument has the advantage of using very little solution, and losing none. Some solutions, such as salts of yttria, do not yield their characteristic spectrum to lowtension sparks, and it is necessary to strengthen the current by interposing a Leyden jar in the circuit, or, what is better, a pane of glass coated on either side with 930 square centims. of tinfoil. The spark should be 3 to 6 mm. in length. The lines of platinum, hydrogen, sodium, and a few of chlorine are visible, but these are known and are measurable. When the solution becomes contaminated with platinum, it may be removed and purified to be used over again if necessary. For such work it is best to use a coil which can yield sparks 170-180 mm. long in air.

For observations on ultra-violet spectra the arrangements described by Soret and by Cornu consist of an optical train of quartz and a prism of 60°, which is composed of two halves each of 30°; one of the two lenses and one half of the prism are out from a right-handed crystal, the other corresponding parts from a left-handed crystal, so that the double refraction of one is corrected by that of the other. One half of the prism may be fixed on the collimator close to the lens, the other in front of the object-glass. For ordinary observations a fluorescent eye-piece is necessary, but generally photography is more convenient. Cornu has used lenses achromatised with colourless fluorspar, but this is not necessary, because the peculiarity of the camera employed by Hartley enables whole spectra to be accurately focussed on one plate if only one prism of 60 degrees be used. The camera back is sloped at an angle of about 22° to the normal,

which brings one end of the plate nearest to the rays of shortest wave-length, and the locus of the foci of all the rays, from the least to the most refrangible, lies upon the plate. There is thus a saving of time in the observation of complicated spectra, with the additional advantage that angular measurements are abolished and linear measurements substituted. Moreover, an increased dispersion and separation of the rays is obtained. This arrangement is most suitable for use with two half-prisms of quartz of 30°. Six hundred lines in the spectrum of iron have thus been photographed with such excellent definition that a magnifying power of 25 diameters was used in their measurement. A quartz lens 75 mm. in diameter and of 75 mm. focus is placed in front of the slit. The camera back is so constructed that by a rack and pinion motion a succession of twelve or fifteen spectra may be taken on one plate. The lenses, which are not achromatised, are of 425 mm. focus for vellow light, and 50 mm. in diameter, the prisms being of corresponding dimensions.

Sparks of high tension obtained in the manner already described are necessary. They may be passed between metallic electrodes 3 to 6 mm. apart.

For photographing spectra yielded by solutions electrodes of graphite are used, or wicks of fine wire drawn from pure gold. The solution is placed in a small I tube; in the shorter limb the electrode is placed, and a platinum wire passes down the longer limb to make connection with the coil. By means of a pipette the tube is easily charged. The graphite electrodes are cut from good sound pieces of Ceylon or Siberian graphite, and are chisel-shaped, with grooves scored along them with the point of a pin. The opposite electrode may be of graphite or of any suitable metal. In order that the strongest discharges may pass from below upwards the lower should be the negative electrode. The admirable work of Lecocq de Boisbaudran on flame and spark spectra (Spectres Lumineux, 1874) not only gives the practical details, but maps of prismatic spectra, and the same applied to a scale of wave-lengths, as well as a complete description of the spectra and a description of each line. The publication proves to be all that a guide to the use of the spect oscope should be, but it deals only with the visible region. In photographing spark spectra the trouble of making drawings is unnecessary, since the photographs themselves are better than any reproduction; all that is required is a description and a map of the principal lines on the scale of wave-lengths. In photographing the spectra of solutions by means of graphite electrodes it is, of course, necessary to ascertain that the material does not yield any of the numerous lines in the spectrum of iron, generally speaking four lines of magnesium with wave-lengths 2801-1 to 2789-6 are visible. Although photography has been applied almost exclusively to the ultra-violet rays and to the infra-red, there is no reason why it should not be used for visible rays, since gelatin plates stained with cyanine, eosine, erythrosine, and some other dyes, render the plates sensitive to the orange, red, and yellow rays. Cyanine is a dve which is sensitive to most of the spectrum as far as the rays of very long wave-lengths.

On the sensitiveness of emission spectra.

The following table gives the sensitiveness of the emission spectra of various elements in fractions of a milligram. It will be observed that radiations in different regions, and excited by different means, greatly vary in emissive power even with the same element.

Photographed ultra-violet spark spectra (Hartley).

Mgr. 1 100,000,000

On ultra-violet spectra. The conditions necessary in photographing ultra-violet spectra, are: 1st, a sensitive salt exerting an equality of action throughout the whole range of the spectrum; 2nd, a perfectly diactinic vehicle to hold the salt; 3rd, a process of development which will not exert a preferential action on any portion of the spectrum. These conditions are fulfilled tain the lines of calcium, with wave-lengths

by the use of silver bromide emulsion, the gelatin being of the purest description, and the image being developed by pyrogallol, hydroquinol, or hydroxylamine hydrochloride and caustic sods. The new developer eikonogen is suitable. Ferrous oxalate, as usually employed, is not to be recommended, because strong lines become developed much more strongly than weak lines. The exposure varies slightly with the sensitive nature of the plates, the width of the slit, the conducting power of the electrodes, the emissive power of the rays to be observed, and lastly with the excellence of the developer. Having once ascertained by comparative exposures how to obtain the best effect, there is very seldom any necessity for altering the exposure.

The following facts have been established regarding ultra-violet spark spectra: 1. When carbon or metallic electrodes, which emit short lines, are moistened or partially immersed in water, the short lines are lengthened. 2. The impurities in a metal, or the minute constituents of an alloy, generally appear as spectra com-posed of short lines. When both electrodes are of the same material, the impurities in minute proportion appear at the negative pole only, but when the proportion of the impurity or alloy is increased, the long lines are seen as short lines at both poles; a further increase in proportion brings them out as long lines. 3. Of the nonmetallic elements, boron, carbon, and silicon exhibit line spectra. The line spectra of the elements are seen in spectra of borates and silicates, and in boracic and hydrofluosilicie acids. 4. The spectra of carbon and silicon may nearly always be detected in photographs taken from electrodes of metallic iron. 5. Insoluble compounds which are not volatile, such as ferrous sulphide, ferric oxide, and ferrous phosphate, do Insoluble, though not yield spark spectra. somewhat volatile, compounds, such as thallium chloride, yield a feeble spectrum of metallic lines. 6. With the exception of boron and silicon, the non metallic constituents of a salt do not affect the spark spectra of solutions. 7. The spectrum of a metallic chloride, nitrate, or sulphate yields spectral lines identical in number and position with the principal lines of the metal itself. Some of the short lines become long lines, but whether the spectra are produced by metallic electrodes or solutions their character is identical. 8. The effect of diluting solutions of metallic salts is first to weaken and attenuate the metallic lines, then, with a more extensive dilution, to shorten them, the length of the longest and strongest lines generally decreas. ing until they finally disappear. There are two lines in the spectrum of copper which disappear by attenuation only, and a similar pair of lines in the spectrum of silver behaves in like manner. Both pairs of lines have been observed as short lines in alloys containing very small quantities of these metals. 9. Accidental differences in the passage of the spark, or in the time of exposure of the photographic plate, when the normal period varies from half-a-minute to five minutes, do not cause sensible variations in spectra obtained from the same substances, under any ordinary circumstances. 10. Spectra of metallic

2967.3 and 8933, also occasionally those with wave-lengths 3736.5 and 3705.3. These calcium lines are due to dust when the electrodes are dry, and to impurity in the acids when solutions are prepared therewith and examined. 11. Five modified spectra have been observed in photographs taken from graphite electrodes. which apparently belong to no other element but carbon. The first and second were produced under identical circumstances, and were taken from dry points in air. The first contains 20 lines, the second only 12. The third was taken from wet electrodes in air, and consists of 20 lines, some of which are lengthened. The fourth was taken from dry electrodes in oxygen, and consists of 17 lines, some being much lengthened. The fifth was taken from dry electrodes in carbon dioxide, and consists of 18 lines, all much lengthened and strengthened

(T. pt. i. 1884).
The examination of metals and altoys. When a metal is to be examined it may be filed or hammered into electrodes of a convenient shape, and held between screw clips or between the points of cheap drawing pens. According to circumstances, both electrodes need not be of the same metal, but one may be of gold, platinum, or a tin-cadmium or lead-cadmium alloy containing in either case 20 p.c. of cadmium. Such an alloy gives convenient reference lines. If it be required to bring out the lines of the constituent of an alloy present in the metal in minute proportion, or present as an impurity in the metal, it is best to partially immerse the lower electrode in water contained in a small glass J tube, as if a solution were being photographed. Under these circumstances the short lines become much lengthened and consequently more prominent. The best form for electrodes is flat with curved edges, or even somewhat rounded discs, such as blow-pipe globules flattened.

The identification of lines in photographed pectra. When the spectrum of an alloy, metallic precipitate, or solution has been photographed, it is seldom easy to determine what substances are present or absent, partly on account of the complexity of the spectra and partly from the absence of colour. It is necessary in such cases to have recourse to one or both of the following methods of identification. (a) Method of identifying the elements by lines photographed from a known specimen. A series of photographs taken from metallic_electrodes and from solutions should always be kept for reference. A substance may then be readily identified even when the wave-lengths of its lines are unknown, by superposing one photograph on the other, film to film, since there are but very few cases of actual coincidences of lines of similar character belonging to different elements. If this examination does not account for all the lines, it is necessary to proceed according to the next method. (b) Method of identifying lines when comparison-spectra are not available. By chemical processes of separation it is easy to ascertain what metals may be looked for. The wave-lengths of the unrecog-· nised lines may then be ascertained by measurements and reference to an interpolation curve. The measurements need not be made with a

micrometer unless great accuracy is required. It suffices generally to measure the spectra by means of an ivory scale with bevelled edges, the divisions on the scale being hundredths of an inch. With a strong magnifier we may read by judgment to tenths of a division or thousandths of an inch. The best form of magnifier is made like the compound eyepiece, of a microscope with cross hairs or fibres of cocoon silk in the field. The lens is placed very close to the surface of the scale and photograph, so that false readings caused by parallax are avoided. When all the lines in a photograph which have been recognised, or vice versa, have been pricked off, the scale is very carefully adjusted so that it gives correct readings with lines of known wavelengths at different parts of the spectrum, such for instance, with Nos. 9, 10, 11, 12, 17, and 25 of cadmium. In order to adjust the scale accurately, it is advisable to rule a line along the whole of the spectrum, which may be done when photographing by placing a wire at right angles to the slit, and one-third or one-fourth the length of the spark, above the lower electrode. The edge of the scale is applied to this line, and held in position by spring clips or screws. The scale numbers of the unrecognised lines are then read off, and by reference to the interpolation curve their oscillation-frequencies or their wavelengths are obtained. From maps, or descriptions of spectra, accompanying a list of wavelengths, the corresponding lines are selected and identified.

Descriptions of the spectra of the elements. Emission spectra. The spectra of non-metallic elements, particularly those which are gaseous, have been found to vary in character with the conditions under which they have been obtained. Thus N, O, C, Br, I, S, Se, Te, and P yield band spectra or, line spectra, according to variations in temperature or pressure. The chlorides of B and Si likewise give line spectra due to Band Si; under certain conditions they emit spectra of their own. The fluted spectrum of carbon has given rise to great discussion. Swan, and later Angström, attributed the bands to a hydrocarbon, so also did Morren, and Liveing a. Dewar, but they finally arrived at the conclusion first enunciated by Attfield, that the bands were caused by the element carbon. Van der Willingen, Plücker and Hittorf, Marshall Watts, Wüllner, Lockyer, and Fievez, have all adduced evidence of this. It appears, however, that a banded spectrum of cyanogen can be obtained which is distinct from that of carbon. Certain bands in the ultra-violet spark spectrum, which have been considered by Liveing and Dewar to be caused by cyanogen, have been observed by Hartley, and he is led to the conclusion that they are in reality carbon bands intensified by the presence of an atmosphere of nitrogen, but not cyanogen bands, for the reason that they cannot be obtained from various cyanogen compounds, such as soluble cyanides. They are always. present when graphite electrodes are used in air, they are intensified when the electrodes are moistened, and they become particularly strong when concentrated solutions of chlorides, such as zine chloride or calcium chloride, surround the electrodes; moreover, the strength of the bands increases with the strength of the solutions.

A review of the facts shows that large mole-

cules give banded spectra, as is evident from the spectra of compounds, and various other considerations lead to the conclusion that the elements which give such are capable of existence in different molecular conditions, the most complex molecules emitting bands of rays, the simpler molecules emitting line spectra.

Hydrogen. When sparks are passed through hydrogen, four very well known lines appear. Huggins has observed the same in some stars, together with a remarkable series of lines in the ultra-violet, and it has been surmised that the whole series, visible and invisible, belong to the one element. Cornu has recently proved this to be the case. Fifteen lines in the visible and ultra-violet constitute the only true line spec-

trum of hydrogen.

The alkali metals, Li, Na, K, Rb, Cs. These metals are distinguished by the fact that most of their salts are decomposed in the flame, and the metal set free, or the metallic oxide formed from it, is sufficient to colour the flame intensely. The spectra are very simple, and all the principal lines are in the visible region. Their ultra-violet spark spectra are insignificant.

The alkaline earth metals, Ca, Sr, Ba. The spectra of these elements are obtainable by flames. When the chlorides are fused and heated in a flame supplied with hydrochloric acid, lines due to the metallic chlorides are visible. Without hydrochloric acid, the spectrum is at first a simple line spectrum, but subsequently bands, shown by Mitscherlich to be due to the oxides, take their place. Feeble sparks give line spectra with solutions of salts. In the ultraviolet, a series of well-marked groups of doublets and triplets is seen.

The magnesium group, Be, Mg, Zn, Cd. The element beryllium stands at the head of two families, that of the alkaline earths and the magnesium family. It occupies a position similar to that of lithium with regard to the alkali metals and the copper and silver family. Its spectrum is similar in many respects to that of lithium, being very simple and composed of iso-lated lines. There are two in the blue and five in the ultra-violet not visible in the flame, but obtainable by the action of condensed sparks. Magnesium and the compounds of the other metals of this group do not easily yield flame spectra, but give characteristic groups of lines when solutions are submitted to feeble or condensed sparks. In the ultra-violet these consist of well-marked groups of isolated lines, pairs, triplets, and groups of four and of five lines.

The aluminium elements, B, Al, Ga, In, Tl. Boron, which stands at the head of this group, gives a flame-spectrum only of its oxide, but the boron compounds, such as borates, emit three lines in the ultra-violet due to this element. Aluminium gives no flame spectrum, but gallium, indium, and thallium emit rays in the violet and green. Sparks taken from solutions of indium and thallium yield characteristic spectra in the ultra-violet consisting of many isolated lines and pairs of lines.

The tin elements, C, Sn, Ge, Pb. Carbon presents a very simple spectrum when condensed sparks are used; most of the lines are in the ultra-violet. It is a remarkable fact that under the same conditions the number of lines some-

times varies, and no satisfactory reason for this can be assigned. Four spectra of graphite have been mapped from photographs described as follows: 1. Dry electrodes in air. 2. Wet electrodes in air. 8. Dry electrodes in oxygen. 4. Dry electrodes in carbon dioxide. The strength and length of the lines vary under certain circumstances; in 1 the lines are all short, in 2 some lines are lengthened, in 3 some lines are much lengthened, and in 4 all the lines are lengthened and strengthened.

The spark spectra of tin, germanium, and lead contain numerous lines which are not characterised by any evident special grouping. The ultra-violet spectrum of germanium has yet

to be photographed.

The group of rare earths, Ce, La, Di, Sm, Yt, Sc, Er, Tr. These elements give no flame spectra, and but weak spectra with feeble sparks. Ce, Di, Yt Sm, Sc, Tr yield very complicated spectra to powerful sparks, the spectrum of cerium in the ultra-violet being remarkable for the immense crowd of lines. Attrium and scandium chlorides give spectra composed of bands which are very characteristic in the visible region. Didymium, samarium, erbium, and thallium will be dealt with under the head of Absorption spectra. Lanthanum gives a large number of lines in the visible region, but very few in the ultra-violet.

The nitrogen elements, N, P, As, Sb, Bi, V. Nitrogen gives a large number of lines under the action of condensed sparks. The ultra-violet portion of the spectrum has been photographed. Nothing of the same kind is known of phosphorus. Phosphorus in a current of hydrogen gives a beautiful banded flame spectrum, especially when the flame is cooled. This reaction is exceedingly sensitive. The spectra of arsenic, antimony, and bismuth in the ultra-violet are very well marked, and they each contain a large number of lines, some of which are nebulous, others are mere dots, and there is a characteristic background of continuous rays. Vanadium yields spark spectra, with a large number of lines.

The chromium elements, Te, Cr, Mn. The line spectrum of tellurium obtained from the element is very complex, and by far the greater number of lines are in the ultra-violet; the character of the spectrum resembles those of arsenic, antimony, and bismuth. The chromium and manganese spectra are very complex and similar to those of the iron group.

The iron, nickel, and cobalt group. These metals present very complicated spectra when condensed sparks are employed in the visible, and more particularly the ultra-violet, regions. The grouping of the lines in the dif-

ferent spectra is similar.

The palladium, gold, and platinum These elements present complicated spectra, though less so than the foregoing. The strong lines of gold are few in number. These metals do not excel in emissive power. Feeble sparks with them give feeble spectra. Iridium gives a spectrum only with condensed sparks, which in the ultra-violet consists of a great crowd of lines.

The spectra of many elements, such as tungsten and uranium, have yet to be examined

thoroughly. It may here be remarked that elements usually associated by their natural occurrence, or by classification according to their chemical properties, exhibit spectra with characters in common.

A very important paper by Mitscherlich (A. 121, 459) first drew attention to the fact that a number of compounds emit distinct spectra, for the most part band spectra. A list of such compounds here follows, most of the gpetra of which were originally described by Mitscherlich. Diacon also (Thèses de Physique et de Chemie, Montpelier, 1864), using a flame the interior of which was fed with chlorine, obtained distinct spectra of chlorides, such as those of the alkaline earths, gold, lead, iron, cobalt, and nickel; the alkalis gave no spectra excepting where they became converted into oxides or metal, as in the mantle of the flame.

Other observers have discovered and described specific spectra emitted by the following compounds:—Al₂O₃; feeble sparks (Wüllner and others). NH₃; flame (Dibbits). CO; spark others). NH₃; name (Dibbits). CO; spark (Plücker and others). CN; flame (For Talbot, Draper, Dibbits, and others). Er₂O₃ and ErPO₄; flame (Bunsen a. Bahr). MgO and hydride of Mg; flame and spark (Liveing a. Dewar). PH₃; flame cooled (Christofle a. Beilstein). SiCl. SiBr, SiI, spark (Plücker, also Salet). H.O.

flame (Liveing a. Dewar; Huggins).

Harmonic relations between the lines of a spectrum. The self-luminous nature of a molecule is connected with the vibrations of those The number of vibrations is indicated by the inparts of the molecule which are called atoms. verse wave-lengths of the lines in the spectra. The spectrum of iron contains more than 1,200 distinct lines, and it follows, therefore, that the molecule or its atoms must simultaneously excite as many different vibrations. We are acquainted with similar relations in acoustics. For instance, it has been observed by Hipkins that the simplest vibration of a pianoforte string will cause it to emit its own proper note, and as many as twenty-four overtones or harmonics. Johnstone Stoney first discovered such harmonics in spectra. The visible spectrum of hydrogen contains the three lines Ha wavelength 6563.9, $H\beta = 4862.1$, $H\delta = 4102.4$, these are the 20th, 27th and 32nd overtones of a vibration. of which the wave-length = 0 013127714 mm. But the fourth line $H\gamma = 4341$, and the lines in the ultra-violet do not fall in with this system. Soret has calculated the harmonics of the three groups of triplets in the magnesium spectrum to be the 20th, 27th, and 31st harmonics of the fundamental vibration. Similar groups occur in the cadmium spectrum, which are the 20th, 23rd, 27th, and 31st of a fundamental vibration. Schuster has observed several harmonics in the

bismuth, calcium, thallium, and gold. According to Mascart, sodium has five series of doublets which are the 132nd, 138th, 143rd, 158th, and 163rd harmonics. One of the most remarkable spectra is the absorption caused by chromyl chloride. Johnstone Stoney and Emerson Reynolds have shown that under great dispersion and lime-light illumination it gives a series of harmonics which are similar to those of a violin string, and of which the order lies between 628 and 733. Liveing and Dewar have observed that many ultra-violet spectra contain lines which are harmonically related, not so simply related perhaps as the harmonics of a uniform stretched string, but like the overtones of a string which is not of uniform thickness, or is loaded at different points, similarly related in origin though not exact harmonics. Lithium, potassium, calcium, magnesium, and zinc are such elements. The alkali metals have each one series in the visible spectrum, and another in the ultra-violet. It may happen in other cases that two or more such series overlap, and it may be very difficult to distinguish and separate them. There is a remarkable fact to be noted with regard to ultraviolet spectra, namely, that similar groups of lines, evidently harmonically related, are alternately sharp and nebulous in character.

Huggins discovered that the four hydrogen lines in the solar spectrum are part of a much longer series of lines which occur in the spectra of white stars. Cornu discovered the whole series in the spectrum of pure hydrogen, and Balmer showed that the whole series of lines can be expressed by the following formula:

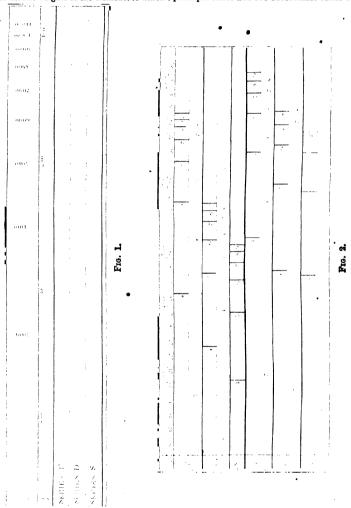

$$N_{m-2} = k\left(1 - \frac{4}{m^2}\right)$$
, in which k is a constant

for the whole series, and by substituting the whole numbers 3, 4, 5, 6, &c., for m, we obtain values for N which are the oscillation-frequencies of the successive lines.

Relations between the spectra of different elements. Lecocq de Boisbaudran has observed such a relationship between the lines in the different spectra of the alkali metals and their atomic weights, that he has been able to calculate the atomic weight of gallium from its spectrum. It may be stated that the atoms of greater mass vibrate more slowly, and therefore emit rays of proportionally greater wave-lengths. Ciamician made an extended series of observations on the spectra of elements usually classed together on account of their chemical properties. and he described several of these spectra as being homologous, that is to say, similarly constituted. A. Grünwald observed mathematical relations between the spectrum of water vapour and the line spectra of H and O, which led him to predict the existence of many lines in the spectrum of water vapour which had not been photo-graphed. By prolonged exposures, Liveing and Dewar obtained photographs of a number of lines approximating very closely to those calculated by Grünwald.

Hartley, in 1883, observed the law of homology in the visible and ultra-violet spectra of the magnesium, zinc, and cadmium group. Elements with properties in common exhibit spectra with Schuster has observed several harmonics in the similar groupings of lines, but the dispersion of spectrum of strontium; also in the spectra of the lines and the refrangibility of the strong lines in each group vary with the atomic weights of ; the elements. In each spectrum the differences between the oscillation-frequencies of the individual lines of each triplet is a constant quantity. The law also applies to the series of doublets. The differences between the oscillation-frequencies of individual rays in the series of triplets increases with the atomic weights of the elements to which

who it appears recognised it independently in 1885. J. S. Ames, in 1890, proved the perfect homology, line for line, of the arc spectra of zinc and cadmium. Kayser and Runge have shown that the series of triplets referred to in the magnesium, zinc, and cadmium spectra are in reality three series of harmonic vibrations, a principal series and two subordinate series over-

the triplets belong. A survey of these facts led to the conclusion that as the molecules of these elements contain but one atom, the atoms have a complex constitution, and that those elements the spectra of which are homologous are composed of the same kind of matter in different states of condensation, the molecules having similar modes, but different rates, of vibration. The law

lying each other. The magnesium series they place along with those belonging to the calcium, strontium, and barium family, but according to the periodic law, the magnesium spectrum might be expected also to stand at the head of the spectra of the family which includes zinc and cadmium. The series of lines in the alkali and alkaline earth metals do not fall in with Balmer's law for the of homology has been studied by J. R. Rydberg, hydrogen lines. Homology has been observed in the spectra of the following groups: lithium, sodium, potassium, rubidium, exsium, also in aluminium, indium, thallium. Runge announces that doublets and triplets existing in the spectrum of an element can be arranged in series which show an appearance of great regularity, and are seemingly analogous to the overtones of a vibrating body (see figs. 1, 2, and 3). In fig. 1 the spectrum of sodium is shown with a scale of unequal parts, A corresponding to wave-lengths,

and a scale of equal parts 1 corresponding to

oscillation-frequencies. The lines forming the entire spectrum are arranged in three series. Each line in the maps indicates a closely-placed pair of lines. Series P is the principal series, series D is the subordinate series of diffuse lines, series S the subordinate series of sharp lines. The three series are regular, the intervals between the lines decrease as the wave-lengths of the lines diminish from right to left. In fig. 2 we have similar maps, but the scales run the reverse way, from left to right. The principal and subordinate series of lines are shown in the spectra of Mg, Ca, Zn, Cd, and Hg. Corresponding lines in two different series of the same spectrum are numbered alike. The homology of the spectra is evidenced, and also variations following increase of atomic mass in elements of the same group. In fig. 3 the homology of

determined the composition of some homogeneous alloys of gold and silver, also of lead and cadmium, by comparison of their spectra with check pieces of known composition. Sir J. G. Alleyne estimated phosphorus in iron and steel, and Ballman attempted the estimation of lithium by the spectroscope. Liveing and Dewar made observations on a spectroscopic method of estimating sodium by measuring the width of the sodium lines. Hartley determined the different spectra emitted by solutions of different strengths, and found these constant when the ultra-violet lines were photographed. Accordingly, by comparison, the metals may be determined in solutions made from determinate weights of material, diluted to a definite volume. Quantitative determinations of the basic constituents of limestones, of copper in pyrites cinder, and of lead, silver, and copper in zinc blende, have been made with quantities of matter so small that no other method could have dealt with them. It will be seen later on, that absorption spectra are serviceable in quanti tative analysis.

Spectra of the infra-red region and spectra of solids in vacuo. There are three methods of spectroscopy which have not yet been much employed. 1. The method of E. Becquerel for observing the infra-red rays. This is accomplished by the use of an eyepiece covered with Balmain's phosphorescent paint. When it is excited by exposure to a brilliant

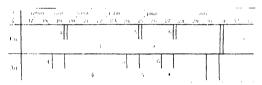

Fig. 3.

the spectra of copper and silver is well shown. The difference of two consecutive oscillationfrequencies decreases as these values increase, and there seems to be a finite limit to the oscillation-frequencies of a series. If n represent whole numbers, the oscillation-frequencies of a series may, with great accuracy, be represented by the formula $A - Bn^{-2} - Cn^{-4}$, where A, B, C, are positive constants. B has nearly the same value for all the series of the different spectra.' A is the limit towards which the oscillation-frequency tends when n increases. For elements that are chemically related the series are distinctly homologous, both in appearance of the lines and the values of A, B, C, and with increasing atomic weight they shift towards the less refrangible end of the spectrum. The spectra show relationships between the elements similar to those between their chemical proper-

Quantitative analysis by the spectroscope. In 1862 W. A. Miller first attempted to apply the spectroscope to the quantitative estimation of the constituents of an alloy. Jansen, in 1870, proposed two methods of quantitative analysis. Champion, Pellet, and Grenier successfully applied a spectro-photometrical method to the estimation of alkalis. Lockyer and Roberts-Austen

light, it glows, but as soon as any radiation of very low refrangibility falls upon it the phosphorescence is destroyed. 2. Abney observes the same rays by means of specially-prepared photographic plates, sensitive to exceedingly slow vibrations. Even the radiations from a kettle of boiling water can impress themselves permanently on his preparation of silver bromide. V. Schumann and also Waterhouse have used photographic plates prepared with cyanine, erythrosine, and other dyes for the same purpose with some success. 3. Crookes has made much use of the phosphorescent spectrum obtained by the action of an electric discharge in high vacua, and has made a most interesting series of observations on the rare earths by this means. Among other results he has proved the wide distribution of yttria, its occurrence in strontianite, coral, oyster shells, and limestones. He considers that there are several kinds of yttria with different phosphorescent spectra, but as they all give the same spectrum when excited by the spark in the usual manner, they must be considered as being derived from the same elementary yttrium.

Absorption spectra. In dealing with absorp-

Absorption spectra. In dealing with absorption spectra, we may observe the effect on a continuous spectrum of (a) gases, (b) liquids, (c)

solids. When rays enter a transparent medium—either gaseous, liquid, or solid—they do not leave it in a condition identical with that in which they entered it. They may be either partially absorbed or altered in refrangibility. No known substance is capable of transmitting radiations of all known wave-lengths; those media which do not absorb appreciably any of the coloured rays, or any of the rays in the ultra-violet which are capable of being photographed, absorb a portion of the infra-red spectrum. It may be remarked that substances like air and water which in thin layers do not appear to absorb the rays in the visible spectrum, in thicker layers are seen to absorb the rays of a limited region. The A and B groups of lines in the solar spectrum have been shown to be due to oxygen in the atmosphere, while nine lines lying between the two D lines in the solar spectrum were observed, and proved by Josiah P. Cooke, in 1866, to be caused by water vapour in the atmosphere amounting to not more than 1.5 g. in 100 litres of air. With 0.18 g. only one line was visible, and with 0.55 g. two lines. The successful application by Piazzi Smyth of the spectroscope to weather forecasts is based upon such facts.

Many cases of absorption are known in the. infra-red and in the ultra-violet, when no visible rays are absorbed. Colours may be either visible or invisible; since we must regard every substance which absorbs rays as coloured. The eye cannot always distinguish colour, because the most sensitive eve cannot observe the rays which are absorbed by its own aqueous humour, and are thus prevented from affecting the optic nerve. Hence the infra-red rays have no effect upon the retina, and most of the ultra-violet cannot affect it. The colour of a substance is determined by the combined effect of the rays which are not absorbed. Cobalt glass, which absorbs the yellow and green rays, transmits the red, blue, and violet, but as it transmits comparatively little of the red its colour appears blue. The purity of the light by which the substance is examined is of importance. Chromium solutions which are green by daylight are red by gaslight, because the yellow and red rays are predominant in gaslight, and as the red rays and the green are transmitted by pure white light, the dominant colour is red by light of less purity. There is but little importance to be attached to the general absorption of rays, but well-defined absorption bands afford evidence both of the composition and the constitution of substances.

The theory of absorption spectra. It is a well-known fact in acoustics that a vibrating musical instrument, a tuning-fork, or a stretched string, will communicate its vibrations to any similar instrument near to it which is capable of similar vibrations, and a sufficient number of strings or tuning-forks can entirely absorb the vibrations of a similar string or fork. In like manner when a molecule of a substance is capable of vibrating synchronously with a radiation, the rays received on the substance are absorbed by reason of the molecules being put in motion by the waves which strike them. The absorption is complete if the direction of vibration of the rays and of the molecule is the same, but the phase is opposite. A general absorption appears fin the ultra-violet at any rate) to be due

to the vibration of the molecule, while selective absorption appears to be caused by the vibrations of atoms within the molecule. When a substance in solution absorbs all the rays of a certain region of the spectrum which fall upon it, it is because the molecules are vibrating synchronously with these rays, and the number of molecules present is sufficient to damp all the vibrations. When the rays traverse a smaller quantity of substance—as, for instance, when a solution is diluted - the number of molecules present is not sufficient to damp all the vibrations, and some rays pass through. If, however, certain atoms within the molecule are vibrating synchronously with certain rays, we shall have a selective absorption of these rays after the general absorption has been so weakened by dilution as to allow them to pass. It has been shown by Hartley that the vibrations of the atoms depend upon the rate of vibration of the molecule, or in other words, the rate of vibration of the molecule determines the rate of vibration of its parts. Four absorption bands in the three hydrocarbons benzene, naphthalene, and anthracene are evidence of this. The mean rate of vibration of the rays absorbed by naph-The mean thalene and anthracene is less than that of the rays absorbed by benzene, and the vibrations of the carbon atoms within the molecule are not independent of, but are a consequence of, the molecular vibrations; they must, in fact, be regarded as overtones or harmonics of the fundamental or molecular vibrations. When the rate of the fundamental vibration is reduced by an increase in the mass of the molecule, the rate of vibration of the carbon atoms is reduced in a similar ratio. Greater amplitude of vibration means a louder note, or in the case of luminous radiations a brighter light. Consequently the converse of this may be considered to hold good, that a greater intensity of absorption is caused by a greater amplitude of vibration in the molecules of the absorbing medium, the number of atoms or molecules remaining constant.

An examination of the three hydrocarbons benzene, naphthalene, and anthracene shows that the mean rate of vibration of the rays absorbed by benzene is greatest, naphthalene comes next, and anthracene is least; but the absorptive power is in the reverse order, that of anthracene being greatest. Hence we conclude that the amplitude of vibration is greater as the rate of vibration is slower (C. J. 1881). The approximate rates of vibrations of the three hydrocarbons are given as follows:—

	ave-length absorbed.		lar vibra- r second.	Molecular weights.
Benzene	2526	1,248	billions	78
Naphthalene	2687	1,177	***	128
Anthracene	8489	910	**	178

The various absorption spectra may be referred to in no better order than that of the refrangibility of the rays absorbed.

tion, the rays received on the substance are absorbed by reason of the molecules being put in motion by the waves which strike them. The absorption is complete if the direction of vibration of the rays and of the molecule is the same, but the phase is opposite. A general absorption acid, chloroform, carbon tetraphate is opposite. A general absorption acid, chloroform, carbon tetraphate is opposite. A general absorption acid, chloroform, carbon tetraphate is opposite. A general absorption acid, chloroform, appears (in the ultra-violet at any rate) to be due

lines, which, however, do not appear in carbon compounds containing no hydrogen; they do not all appear in some hydrogen compounds. The inference is that they belong to hydrogen. When oxygen is present as a part of hydroxyl it obliterates the rays between two of those lines which are due to hydrogen. When it forms part of the carbon nucleus of a compound, as it does in aldehyde, the spectrum is inclined to be linear, or the bands are bounded by well-defined lines. There appear to be characteristic bands which indicate the carbon nucleus of a series of substances. Certain radicles have a distinctive absorption lying near \$\lambda 7000 and others about λ 9000; thus in the three compounds C₆H₈, C₈H₅,H₂N, C₆H₄(C₂H₅).H₂N we have the following coincident bands probably due to the benzene nucleus; the line \(\lambda \) 8670 is the principal one; λ 8670, λ 8670 to 8720, λ 8720 to 8850, a fourth band about λ 9300, a fifth about λ 10400-10660. In benzene and ethyl-aniline there occurs a band also at \$10970 to 11050. If the line \$8670 is associated with a band, it is almost certain to be caused by the benzene nucleus. Ethyl compounds are indicated by absorption at \(\lambda \) 7410, λ 8950 to 9030, 9040 to 9070, 9130 to 9180, 9270 to 9300.5, 9320 to 9420. The solar spectrum shows an absorption at A 8660, and, with the excention of the line at 7410, the absorptions noted above have been observed to be coincident with bands or lines in the solar spectrum.

Visible and ultra-violet absorption spectra. The absorption spectra of the coloured region were long since carefully studied by Gladstone. These spectra pass gradually into the extreme violet and ultra-violet. In dealing with the subject it will be convenient first to consider the absorption caused by gases and vapours, elementary or compound, then the absorption by inorganic salts, and lastly the spectra of organic substances.

hydrocarbons and ter-

Organic suostances which exhibit absorption spectra. All benzenoid hydrocarbons and tentary bases derived from the same. All haloid, hydroxyl, carboxyl, and amide, derivatives of benzenoid hydrocarbons. Cyanuric and uric acids, with colouring matters derived therefrom. Albumens and allied substances. Organic colouring matters of unknown constitution, such as chlorophyll and hæmoglobin. Many alkaloids and their derivatives, e.g.: Aconitine, pseudaconitine, japaconitine, morphine, narcotine, codeline, papaverine, oxynarcotine, apomorphine hydrochloride, tetracetylmorphine, diacetyl-

containing hydrogen show the same group of codeline, quinine, quinine sulphate, cinchonine sulphate, which, however, do not appear in carbon sulphate, quinidine sulphate, cinchonidine sulcompounds containing no hydrogen; they do phate, veratrine, piperine, brucine, strychnine.

The relation of absorption spectra to the chemical constitution of carbon compounds.

1. Substances with a nucleus consisting of an open chain of carbon atoms transmit continuous spectra and are highly diactinic. Examples: the alcohols, acids, ethereal salts, haloid ethers, and the carbohydrates. 2. In homologous series the greater the number of carbon atoms the shorter the transmitted spectrum. 3. In substances with the same carbon nucleus that containing the most oxygen transmits the shortest spectrum, as, for instance, in acids the spectrum is shorter than in alcohols, and in dibasic shorter than in monobasic acids. 4. Substances with a closed chain nucleus when not more than two atoms of carbon are doubly linked transmit continuous spectra, but their absorptive power is much greater than that of open chain compounds; e.g. camphor, benzene hexachleride, and the terpenes, also hexahydropyridine. 5. The more closely the carbons in a closed chain are linked, the greater is the absorptive power of the molecule; e.g. the terpenes withstand dilution more strongly than benzene hexachloride, and camphor. 6. The carbon nuclei of benzenoid hydrocarbons possess strong absorptive power, and after great dilution exhibit absorption bands; e.g. four bands are seen in the spectrum transmitted by benzene when 1 part is diluted with 2,400 parts of alcohol, three bands in naphthalene with a dilution of 1 in 100,000 parts, one band in phenanthrene with 1 in 500,000 parts, and one band in anthracene with 1 in 5,000,000 parts of alcohol. 7. The introduction of radicles in place of hydrogen and of side-chains into the benzenoid nuclei diminishes the number of absorption bands, but increases their width and intensity. 8. The simple union of carbon to nitrogon does not cause selective absorption ; e.g. in hydrocyanic acid and cyanides. 9. When a benzenoid nucleus contains an atom of nitrogen in place of an atom of carbon, the molecule exhibits absorption bands, and its absorptive power is generally not impaired, but is sometimes increased, e.g. picoline, pyridine, quinoline, and their derivatives. 10. Isomerides exhibit different spectra, e.g. the terpenes and isomeric benzene derivatives. 11. When the condensation of the carbon atoms in the quinoline nucleus is modified by the combination therewith of four atoms of hydrogen, the intensity of the absorption bands is reduced but is not de-12. Nitrogen combined with oxygenas in nitroxyl, nitrites, and nitrates—exhibits absorption bands. 13. When several carbon atoms are united by oxygen and nitrogen atoms, the resulting compounds exhibit intense absorption bands, e.g. cyanuric acid, uric acid, and derivatives, including murexide. 14. Molecules of compounds—that is to say, molecules composed of dissimilar atoms-vibrate as wholes or units, and the fundamental vibrations give rise to secondary vibrations which stand in no visible relation to the chemical constituents of the molecule, whether these be atoms or groups of atoms. Hence it appears that a molecule is a distinct and individual particle which is not fully represented by our usual chemical formula.

since these only symbolise certain chemical reactions and fail to express any relation between physical and chemical properties. As certain molecular groupings are characterised by the absorption of rays of particular wave-lengths (absorption bands), it is evidently possible to draw conclusions as to the constitution of substances from their absorption spectra. Many of the foregoing statements may be usefully and clearly summarised by means of formulæ. These render evident how the optical properties of a compound are determined by the skeleton of carbon atoms.

compounds which exhibit selective absorption of the ultra-violet rays are coloured. The subtlety of the colour, however, is such that the eye cannot perceive it without the aid of photography or a fluorescent screen.

That which in the ordinary acceptation of the term is a coloured substance is merely one in which the absorption of rays extends into a region limited by the red and violet ends of the spectrum, or between wave-lengths 7000 and 4000. According to this view, the colour of a substance may be fivisible to the unaided eye. As bands of selective absorption appear to be the

On the cause of colcur in organic compounds. According to 0. With, the tinctorial character of aromatic compounds is conditional upon the simultaneous presence of a colour-producing group and a salt-forming group in the molecule. A group of atoms of the former kind he terms a chromogen, and of the latter a chromophor. He says: 'For instance, NO₂ is the chromophor of nitraniline and nitrophenol, but nitrobenzene is the chromogen of these bodies. The different nitrodiphenylamines are all acids and dye-stuffs, and their tinctorial power increases with the number of nitroxyls.' In this connexion it is of interest to study the relation of the hydrocarbons to the more complex compounds which are colouring matters derived from them.

If a source of light emits all luminous and invisible vibrations capable of being transmitted through 8 feet of air, a perfectly colourless substance will transmit these rays without impairing their intensity. A coloured substance is one which absorbs rays at either end of the spectrum, or selects rays of a definite wave-length from the middle of the spectrum. Every fluorescent substance is therefore coloured, and benzene, benzenold hydrocarbons, phenois, and other derived

effect of vibrations taking place within the molecules of a substance, and these are dependent upon the rate of vibration of the molecules themselves, they are called in general 'molecular vibrations.' If, then, it be desired to convert a substance such as benzene, the colour of which is invisible, into a compound with a visible colour, it is necessary to slacken its rate of vibration so that the molecule will absorb rays with oscillation-frequencies (inverse lengths) occurring within the limits of visibility. That which is called a chromogen is an invisibly coloured substance, and that termed a chromophor is an atom or group of atoms capable of so affecting the molecule as to reduce its rate of vibration, so that it absorbs rays within the limits of visibility. Under certain conditions of combination, nitrogen and oxygen are chromophors, hence also nitroxyl and hydroxyl; that is to say, they are themselves coloured either visibly or invisibly. When two benzene mole-cules are doubly linked by two nitrogen atoms, as in azobenzene, their mode of vibration is profoundly modified, and a brilliant colour as low down in the scale as the yellow rays is the result.

A similar modification takes place when two

atoms of oxygen replace two of hydrogen, as in quinone, which is of a golden-yellow colour. The effect of linking two or more benzene nuclei by carbon atoms has been already dealt with; the colours are not rendered visible, but the molecular vibrations are greatly reduced in rapidity. and the amplitude of the vibrations is much increased. That is to say, the absorption bands are transferred to less refrangible rays, and withstand a much larger amount of dilution. These modifications are both observed in the curve of benzene as modified in trip! envlmethane. The vibrations of this radicle are reduced in rapidity in rosaniline hydrochloride, Hofmann's violet, iodine green, and other such derivatives in which the carbon nucleus remains intact.

There is a family likeness in the curves of azo-benzene, azo-naphthalene, chrysoïdine, and other derivatives of these substances, which is quite in accordance with these observations. In short, in a general way, the change of colour effected by any given series of reactions may be predicted from an inspection of the curve of molecular vibrations of any benzenoid hydrocarbon. Ŵ. Ν. H.

OPTICAL METHODS .- Section 3: ROTA-TION OF THE PLANE OF POLARISATION OF LIGHT.—When a ray of plane polarised light is passed through a plate of quartz cut at right angles to its optical axis, it is found that the plane of polarisation of the emergent ray is not coincident with that of the incident ray; the angle through which the plane has been rotated is called the angle of rotation. If the rotation takes place in the same direction as that in which the hands of a watch move when the face of the watch is looked at, the quartz is said to show dextrorotatory power; if the rotation is in the opposite direction, the quartz is said to show levorolatory power. The symbol + is used to express dextrorotation, and the symbol - to express levorotation. Substances which rotate the plane of polarisation of a ray of light passed through them are said to be optically active.

The polarimeter is an instrument wherein a ray of light can be polarised, the position of the plane determined, the ray passed through a determinate quantity of an optically active substance, and the position of the plane of the

The angle of rotation depends upon (1) the nature of the active substance, (2) the thickness of the layer of the substance through which the

fight passes. (8) the wave-length of the light !

used, and in most cases (4) the temperature.

The composition of the substance examined must then be known; the length of the column of liquid used if the substance be liquid, or the thickness of the layer if the substance be a solid, must be measured; the temperature must be noted-observations ought to be made at a common temperature; and monochromatic light should be employed.

Suppose we are dealing with a liquid carbon compound. Let l = length of column of liquid in decimetres, d = sp.gr. of liquid (referred to water), and a = angle of rotation of the plane of polarisation of light of stated wave-length; then

$$[a] = \frac{a}{l \cdot d}$$

The value of [a] is usually called the specific rotatory power of the substance. It is customary to indicate the light employed by placing a letter to express the wave-length below the bracket: thus [a], means spec. rot. power for light of wave-length D. The spec. rot. power of a liquid as thus defined is the angle through which the plane of polarisation of a ray of light of stated wave-length is rotated by passing through a column one decimetre long of the liquid containing one g. of the substance in 1 c.c.

If a solid compound is to be examined, it must be dissolved in an optically inactive solvent. In this case l = length of column of solution in decimetres, d = sp. gr. of solution, p = g, of optically active substance in 100 g, of solution; then, assuming that the solvent is without influence on the rotatory power of the 100a

dissolved substance, $[a] = \lim_{t \to 0} \frac{1}{t} \cdot p \cdot d$ The question as to the effect of an inactive solvent on the rotatory power of an active substance in solution will be examined later (p. 257).

Connections between optical activity and constitution. Landolt (Handbook of the Polariscope, English trans.) has divided substances which rotate the plane of polarisation of a ray of light into three classes: (1) those which are active only when in the form of crystals; (2) those which are active only when liquid or in solution; (3) those which are active both as crystals and also in solution or in the liquid state. The only substance at present known to belong to the third class is strychnine sulphate. The liquid crystals examined by Lehmann (Z. P. C. 4, 462; 5, 427) probably belong to the first class.

The optical activity of carbon compounds. All compounds which exhibit optical activity unconnected with crystalline form-in other words, all compounds which are optically active when liquid or in solution - are compounds of carbon. Le Bel (Bl. [2] 22, 337) was the first (1874) to trace a definite connection between the optical activity and the constitution of carbon compounds. He was followed by van't Hoff (Bl. [2] 23, 295 [1875]). The subject has been much advanced by van't Hoff in his pamphlet, La Chimis dans l'Espace, and more especially by a small book published in 1887, Dix Années dans l'Histoire d'une Théorie (translated into English by Marsh, and published in 1891, entitled Chemistry in Space).

The hypothesis of Le Bel and van't Hoff

connects optical activity with the presence of one or more asymmetric atoms of carbon in the molecule of the active compound. An asymmetric atom of carbon is one which is in direct combination with four different atoms or radicles. these atoms or radicles being arranged so that any three are similarly situated with regard to the fourth. The conception of the asymmetric atom carries with it the conception of the arrangement in space of the parts of the molecule. The asymmetric atom of carbon is supposed by van't Hoff to be placed in the centre of regular tetrahedron, and a different radiole is supposed to be held by the carbon atom at each summit of the tetrahedron. Two forms of this arrangement may exist, and these forms are geometrically different. Neither is superposable on the other. They bear to one another the relation of an object to its image, or of the right hand to the left, as shown in the figure.

This arrangement corresponds to the enantiomorphous (non-superposable) form of crystals. Ammonium malate, for instance, crystallises in two non-superposable forms, which differ in exactly the same way as the molecules of two geometrical isomerides, each containing an asymmetric carbon atom and both having the composition CR₁R₂R₃R₄, are supposed to differ. If one of the isomerides CR₁R₂R₄, rotates the plane of polarisation to the right, the other rotates to the left. If this hypothesis is to be accepted, every compound of carbon which is optically active must contain at least one asymmetric carbon atom. So far as investigation has gone, this deduction from the hypothesis has been confirmed (v. van't Hoff, Dix Années &c., 31; Landolt, Handbook, 25 et seg.). Further, it has been found that compounds which do not themselves contain asymmetric carbon atoms are inactive, although they are derived from optically active compounds.

There is no doubt that compounds exist which contain asymmetric carbon atoms but do not affect the plane of polarisation of a ray of light. At first sight this fact might be supposed to be irreconcileable with the hypothesis; but the recognition of the existence of inactive compounds containing asymmetric carbon atoms has led to a most ingenious and interesting development of the hypothesis.

Some inactive compounds containing asymmetric carbon atoms can be separated each into two optically active isomerides, one of which is dextrorotatory and the other is isovorotatory. Some inactive compounds which contain asymmetric carbon atoms cannot be separated into active isomerides. Racemic acid, which can be resolved into dextrorotatory and laworotatory tartaric acid, is an example of the first of these classes, called inactive resolvable compounds; mesotartaric acid, which cannot be resolved into active isomerides, is an example of the second class, called inactive non-resolvable compounds.

Inactive resolvable compounds are said, in the language of van't Hoff's hypothesis, to be inactive by external compensation; inactive nonresolvable compounds are said to be inactive by internal compensation.

To understand these expressions consider

the formulæ $(R_2R_2R_1)C.C(R_1R_2R_3)$ and $(R_2R_2R_1)C.C(R_1R_2R_2)$; an italicised C represents an asymmetrical atom of carbon. Each formula contains two asymmetric carbon atoms, and both carbon atoms in either formula are united to the same radicles; in the first formula each C is united to the radicles R_1 , R_2 , R_3 , and $C(R_1R_2R_3)$; in the second formula each C is united to the radicles R_1 , R_2 , R_2 , and $C(R_1R_2R_2)$. The structure represented by one of these formulæ is the reflected image of that represented by the other: hence if one of these geometrically isomeric compounds is dextrorotatory, the other will be laworotatory, and both will rotate the plane of polarisation to the same degree. But if a compound were formed by the combination of equal numbers of molecules of these two geometrical isomerides, that compound would be inactive, for the tendency to righthanded rotation of one part of the compound molecule would be exactly neutralised by the equal tendency to left-handed rotation of the other part. Moreover, if the inactive compound were split into two compounds, one consisting of molecules of the form represented by the first of the above formulæ, and the other of molecules of the form represented by the second formula, then each of these compounds would be optically active, and the compounds would be active in opposite directions. The hypothetical inactive compound $(R_2R_2R_1)C.C(R_1R_2R_3) \times (R_2R_3R_1)C.C(R_1R_2R_2)$ would be said to be inactive by external compensation.

Racemic acid, which is optically inactive, can be resolved into dextrorotatory and hevorotatory tartaric acids. Both tartaric acids have the formula C₂H₂(OH)₂(CO₂H)₂; the hypothesis we are considering represents one of these acids as (H.OH.HOOC) C.C(COOH.OH.H); and the other acid as (H.COOH.OH)C.C(OH.COOH.H); and the hypothesis represents racemic acid as made up of an equal number of molecules of the two active acids, and therefore as a substance which

is inactive by external compensation.

But suppose the molecule of a compound contained two asymmetric carbon atoms, both united to the same radicles but having one half of the molecule the reflected image of the other. then the tendency to right-handed rotation belonging to one part of this molecule would be neutralised by the tendency to left-handed rotation belonging to the other part of the molecule; the molecule as a whole would be incapable of rotating the plane of polarised light, and the compound would be inactive by internal compensation. The general formula of such an in**set**ive compound is $(R_2R_3R_1)C.C(R_1R_2R_3)$.

A compound of this type cannot be resolved into active isomerides, because a resolution into parts is only possible by splitting the molecule, removing one of the radicles, and so destroying the asymmetry of one, or both, of the atoms of

carbon. Mesotartaric acid, which is non-resolv. able, probably belongs to this class of com. pounds; it may have the formula

'H.COOH.OH)*C.C*(COOH.OH.H).

The hypothesis therefore provides for the exis. tence of two classes of optically inactive compounds, both containing asymmetric carbon atoms; the members of one class are resolvable into active isomerides, the members of the other class cannot be so resolved.

Those compounds which contain in their molecules more than one asymmetric carbon atom, each of which atoms is united to the same radicles, whether these radicles are arranged in space in exactly the same way, relatively to each carbon atom, or not, are called by van't Hoff symmetrical compounds; and the term unaummetrical compounds is used to designate those which contain more than one asymmetric carbon atom each of which is united to different radicles. The typical formulæ for symmetrical compounds containing two asymmetric carbon atoms are

 $(R_1R_2R_3)C.C(R_3R_2R_1), (R_1R_3R_2)C.C(R_3R_2R_1), \&c.$ The typical formula for an unsymmetrical compound containing two asymmetric carbon

atoms is (R₁R₂R₃)C.C(R₄R₅R₆).

Unsymmetrical compounds may be either active or inactive; if inactive, they must be inactive by external compensation, and therefore they must be resolvable into pairs of active isomerides. Symmetrical compounds may be active or inactive; if inactive, they may be inactive by external, or by internal, compensation, and therefore they may be either resolvable or not resolvable.

An unsymmetrical compound containing n asymmetric carbon atoms may exist in 2" isomeric forms, which will always be grouped in pairs, one being dextrorotatory and the other lævorotatory. A symmetrical compound containing n asymmetric carbon atoms may exhibit \$2ⁿ active isomeric forms, grouped in pairs of opposite rotatory power, and may also exist in

 $\frac{1}{2}$ non-resolvable inactive modifications (van't Hoff; Dix Années &c., 54-5).

There are three general methods for separating inactive resolvable bodies into their dextrorotatory and lavorotatory isomerides.

In the first method advantage is taken of the differences between the actions of certain minute organisms on the two active isomerides. The second method proceeds by treating the inactive compound with an active body with which one of the isomeric constituents of the inactive compound combines more readily than the other. The third method consists in separating the inactive body into two active isomerides by crystallisation at a definite temperature (van't Hoff. l.c. 63-69).

Racemic acid, which is an inactive compound, can be resolved into equal quantities of rightand left-handed tartaric acid by each of the three methods. When penicillium is allowed to act on a dilute solution of ammonium racemate, lævorotatory ammonium tartrate is found in the solution after a time, the dextrorotatory tartrate having been destroyed by the action of the or-ganism. When a quantity of active cinchonine sufficient to neutralise half of a determinate quantity of racemis acid- is added to a solution of the racemic acid, crystals of levorotatory cinchonine tartrate are obtained, and dextrorotatory tartaric acid remains in solution. When a solution of racemic acid is neutralised by soda, and another equal quantity is neutralised by ammonia, and the solutions are mixed, and evaporated at a temperature slightly below 28°, crystals of two forms are obtained; one set of crystals is dextrorotatory, and the other is levorotatory, sodium-ammonium tartrate. Hoff (l.c. 69) has shown that sodium-ammonium racemate is changed to a mixture of the active isomeric tartrates by heating the dry salt with water, in the ratio NaNH, H, C,O6, H,O:3H,O (the salt crystallises with H2O), to a little under 27°, and that the reverse change is effected by heating the mixed tartrates to a little above 27°. The changes may be represented thus-

centre of figure of the tetrahedron. When the molecule is asymmetric, the centre of gravity will not be situated on any one of the six planes of symmetry of the tetrahedron. So long as the substitution of one radicle by another does not move the centre of gravity of the molecule to the other side of one of the planes of symmetry of the tetrahedron, Guye supposes that the rotatory power is increased or diminished, but is not changed in sign, by such substitution; but that a change of sign of the rotatory power accompanies a substitution which results in moving the centre of gravity of the molecule from one side to the other side of one of the planes of symmetry of the tetrahedron. Guve gives about fifty cases to which he has applied his hypothesis successfully. The derivatives of tartaric acid afford the most complete example.

Replacement of the acidic hydrogen of tar-

$$2(\mathrm{NaNH_4.H_4C_4O_6.4H_2O}) \underset{\leftarrow}{\longrightarrow} 2(\mathrm{NaNH_4.H_4C_4O_6.H_2O}) + 6\mathrm{H_2O}.$$

The racemate crystallises with H₂O, and the tartrates with 4H₂O. Slight variations of temperature above or below 27° determine the direction in which the change shall occur.

The change of inactive sodium-ammonium racemate to a mixture of the active tartrates, and vice versa, is very similar to some changes which occur among inorganic compounds; for instance, when a mixture of MgSO.7H₂O and Na.SO.10H₂O is heated to a little above 21°, it is changed to the double sulphate MgNa₂(SO₄).4H₂O, and water, and this double sulphate is resolved into the two single sulphates at a little under 21°; these changes may be represented thus:—

tario acid by alcoholic radicles is accompanied by increase of rotatory power, and the greater the molecular weight of the replacing alkyl the greater is the increase of rotatory power; thus—

Methyl tartrate
$$[\alpha]_D = +2.14$$

Ethyl , 7.66
Propyl , 12.44
Isobutyl , 19.87

Replacement of the hydroxylic hydrogen of the acid by benzoyl moves the centre of gravity to the other side of the plane of symmetry which is situated between the COOH and OH groups; this replacement is accompanied by a change of sign of the rotatory power. But if the H of the COOH group is now replaced by one alkyl group,

$$MgSO_4.7H_2O + Na_2SO_4.10H_2O \longrightarrow MgNa_2(SO_4)_2.4H_2O + 13H_2O$$
.

Van't Hoff calls the temperature at which such a chemico-physical change as this occurs the transition-point of the system (v. Z. P. C. 1, 165, 227).

Extension of the hypothesis of van't Hoff and Le Bel. The hypothesis of van't Hoff and Le Bel connects the power of rotating the plane of polarisation of a ray of light primarily with the configuration of the parts of molecules, but it points to the formation of molecular aggregates, without change of molecular structure, as a cause of the disappearance of optical activity. Although optical activity is primarily dependent on the arrangement of the parts of certain molecules, and although we cannot assign a definite part of the total rotatory power of a molecule to each atom, or to each group of atoms which together form the molecule, nevertheless a consideration of the constitution of optically active compounds shows that the amount of the activity of any compound is dependent on the greater or less differences between the four radicles which are in direct union with the asymmetric carbon atom or atoms in the molecule of that compound. The greater the differences between the radicles the greater will be the asymmetry of the molecule, and, therefore, the greater will be the rotatory power. An attempt has been made by P. A. Guye (C. R. 110, 714) to connect the degree of asymmetry of the molecule of an optically active compound with the mass of each radicle, and the distance of its centre of gravity from the

the centre of gravity is moved back towards the plane of symmetry already mentioned, and the rotatory power is diminished. Thus—

Dibenzoyl tartaric acid $[a]_D = -117.7$ Methyl salt of , 88.8 Ethyl , , 60.0 Isobutyl , , , 42.0

If acetyl is used in place of benzoyl the rotatory power changes its sign, but the value of the leworotation of diacetyl tartaric acid is less than that of dibenzoyl tartaric acid; the replacement of acidic hydrogen in the diacetyl acid by alkyl radicles decreases the rotatory power, and, as the alkyl radicles of large molecular weight exert a greater effect than the acetyl group, and an effect in the opposite direction, the rotatory power again changes its sign. Thus—

Diacetyl tartaric acid $[a]_{b} = -23\cdot 1$ Methyl salt of , 14·3 Ethyl , , , +1·0 Fropyl , , 6·5 Isobutyl , , , 10·3

Crum Brown (Pr. L. 17, 181) has tried to connect the greater or less rotatory powers of different active compounds with differences between the constitutions of the substituting radicles. Crum Brown admits the influence of the masses of the radicles, but he tries to show that their constitution must also be taken into account. If two methyl groups are introduced into destrorotatory tartaric acid, the salt thus obtained is still dextrorotatory; in this change

two CO.OH radicles have been changed into two radicles CO.O.CH_a. If now this dimethyl tar-trate is treated with acetyl chloride, a strongly isvorotatory dimethyl diacetyl-tartrate is obtained; in this change the CO.O.CH, groups remain, and two OH groups have been changed to two groups O.CO.CH. In the first change, the introduction of the group CO.O.CH, for H altered the rotatory power but did not change its sign, in the second change the introduction of the group O.CO.CH, changed the sign of the rotatory power; therefore, Crum Brown argues, the effect of the radicle O.CO.CH, on the rotatory power is greater than the effect of the isomeric radicle CO.O.CH₃. As the masses of these two radicles are the same, it is evident that the constitution of the substituting radicle affects the rotatory power of the compound.

The specific rotatory powers of compounds often change more or less with small changes in certain physical conditions. Some active Lodies become inactive by heating, and at another temperature the change is sometimes reversed. The values of the rotatory powers of active bodies dissolved in inactive solvents are dependent on the nature and the quantity of the solvent used (v. post, p. 257); the rotatory power of a solution sometimes changes on keeping until a constant value is attained (v. Landolt's Handbook of the Polari-scope, 62). This readiness to change shown by the rotatory powers of carbon compounds finds some explanation in van't Hoff's hypothesis, and especially in the development of it made by Wislicenus. According to Wislicenus (Kön. Sächsischen Ges. der Wiss. 14, 1) the arrangement of the four radicles attached to an asymmetric carbon atom is conditioned chiefly by the affinities of these radicles for one another in the sense that those radicles which have the greatest mutual affinity will tend to get as near as possible to one another; but besides those configurations which are conditioned by the affinities of the radicles, and which will be comparatively stable, other configurations will probably exist con-ditioned by the temperature and by the collisions of other molecules—for instance, the molecules
of the solvent—and these arrangements will be
relatively unstable. These unstable forms may be optically active, as they are only geometrically different from the stable forms, but their rotatory powers will probably differ from those of the stable forms. This way of looking at the question of optical activity enables us to connect the fact that active compounds easily undergo changes in the values of their rotatory powers with the conception which the hypothesis of van't Hoff and Le Bel furnishes of the cause of optical activity.

Molecular rotatory power. The notion of molecular rotation, as the product of the specific rotation into the molecular weight of a substance, was introduced by Wilhelmy (P. 81, 527). Krecke (J. pr. [2] 5, 12) proposed to define molecular

rotatory power as $[m] = \frac{m}{100} \times \frac{a}{l \cdot d}$, where m =

molecular weight of compound, and a, l, and d have the same meaning as before (p. 253); m is divided by 100 to obviate the use of inconveniently large numbers.

Krecke endeavoured to generalise the rela-

tions between the values of [m] for certain com-pounds and bodies derived from, or closely connected with, these compounds. Some years before Krecke's attempt, Mulder (Z. 1868. 58) put forward a statement to the effect that optically active compounds contain certain active radicles, which may be transferred to other active atomic aggregations, and the rotatory powers of the new bodies bear a simple relation to those of the original radicles. Krecke, on the basis of further experimental results, modified and extended Mulder's statement. Krecke announced two generalisations:

(i.) 'When an optically active body forms a compound with an inactive body, or when it is altered by the action of chemical reagents, either the molecular rotatory power of the body is unchanged, or the molecular rotatory power of the new substance is a simple multiple of that of the parent substance.

'(ii.) 'The molecular rotatory powers of iso-merides are multiples of one and the same value.'

Most of Krecke's values were obtained from measurements of substances in solution, and, as we shall see in another paragraph, the results of such measurements are trustworthy only in a few cases. Landolt (B. 6, 1073) made a careful examination of the rotatory powers of tartrates in solution; he came to the conclusion that the value of [m] for tartrates containing a single atom of a monovalent metal is double the value of [m] for free tartaric acid, and that [m] for tartrates containing two atoms of a monovalent metal is three times [m] for the free acid. In this case, Krecke's first statement was confirmed.

In 1885, Oudemans (v. P. B. 9, 635) arrived at the conclusion that the compounds of active bases with inactive acids, and also the compounds of active acids with inactive bases, follow the simple law that 'the molecular rotatory power of a salt, in fairly dilute solution, is independent of the nature of the inactive part of the salt.' This result has been confirmed by the measurements of camphorates and tartrates made by Landolt, of salts of cholic acid by Hoppe-Seyler, of malates by Schneider (A. 207, 286), and of camphorates by Hartmann (B. 21.

221).
This result indicates that the rotatory powers like the extent that the rotatory powers of liquid compounds are affected, by the nature of the radicles which compose them. The rotatory power of a salt in solution approaches to being an additive property, whereas the rotatory power of a liquid compound is a constitutive property (cf. Ostwald, Lehrbuch, 1, 499 [2nd ed.]).
Optical activities of bodies in solution. The

specific rotatory power of an active substance in an inactive solvent has been defined (p. 253) as [a] = $\frac{100a}{l \cdot p \cdot d}$, where l = length of column of solution in decimetres, d = spec. grav. of the solution, and p = g. of active substance in 100 g. of the solution. This formula is expressed in more general terms as $[a] = \frac{n \cdot a}{l \cdot g \cdot d}$, where n = g. of solution containing g g, of the substance; in this case, 1 c.c. of the solution weighs d g. and contains $\frac{g.d.}{n}$ g. of the active substance.

This formula assumes that the rotatory power of the dissolved active substance is not affected by the inactive solvent. In 1838 Biot (A. Ch. [3] 36, 257; cf. 59, 206) found that the rotatory power of tartaric acid in aqueous solution increased with increasing dilution; that solutions of equal concentration, of the same active substance in different inactive solvents had different rotatory powers; and that the same inactive solvent raised the rotatory powers of some active substances, and decreased the rotatory powers of others. Results similar to those of Biot were obtained by Oudemans (A. 166, 65; 182, 33), Hoorweg (Maanblad voor Naturwet, 3, 12 [1873]), and Hesse (A. 176, 89, 189).

Landolt (A. 189, 241; B. 21, 191; Handbook of the Polariscope, 80-94) made many observations on the effect of inactive solvents on the rotatory powers of active substances; he came to the conclusion that the specific rotatory powers of such solutions are expressed by equations of the following forms: [a]=A+Bq, or

$$[\alpha] = A + Bq + Cq^2$$
, or $[\alpha] = A + \frac{Bq}{C+q}$, where A, B,

and C are constants, and q is weight of active substance in 100 pts. of the solution. Which formula must be employed is discovered from the results of several observations made with solutions of different concentrations in different solvents. In some cases the observed values of [a] for liquid compounds agree with the values calculated from series of observations of a for solutions of the same compounds. Thus Landolt got the following results:—

on the solubility in water of the salt used; the greater the atomic weight of the metal, the greater was the concentration whereat the change began, and the greater was the difference from the normal state of the salt. Schneider (A. 207, 257) found that the rotation of an aqueous solution of malic acid was right-handed in concentrated solutions, left-handed in dilute solutions, and at 34 p.c. was equal to zero. These observations, and others of a similar character, seem to me to show that observations of the rotatory powers of solutions of solid compounds cannot be applied, at least not in all cases, to draw conclusions concerning the connections between the rotatory powers and the chemical constitutions of the compounds themselves. There is undoubtedly an action of some kind between the molecules of the active dissolved substance and the molecules of the inactive solvent. Molecular aggregates of the solid substance may be broken down by the solvent, or the solvent may form a series of unstable compounds with the dissolved substance, or the solvent may bring about changes in the configuration of the atoms which form the molecule of the dissolved body, or the dissolved compound may be electrolytically dissociated into ions by the solvent. Some of these actions may occur in certain cases, and others in other cases. The action of much water on active salts dissolved therein seems to consist in the electrolytic dissociation of the salts into their ions.

Magnetic rotatory power. Following observations made in 1871 by A. de la Rive (A. Ch. [4] 15, 57), Becquerel in 1877 (A. Ch. [4] 22, 5) made a number of measurements of the rotations.

It is not possible to determine with certainty whether the true values of [a] for solid compounds can be determined from observations on solutions of such compounds. In some cases the values obtained seem to approach constancy when the solutions become very dilute; but according to Pribram (B. B. 1887, 505; B. 20, 1840), who used a very delicate method of measuring, [a] does not certainly attain final constant values in aqueous solutions of tartaric acid, nicotin, and cane sugar, even with very great dilution. R. von Sonnenthal (Z. P. C. 9, 656) determined [a] for dilute aqueous solutions of normal and acid tartrates of K, Na, Li, and NH,; he found that [a] decreased as dilution increased, but that when the solutions became very dilute (c. '4 to '2 p.c. salt in solution) [a] began to increase as dilution still further increased. conclusion come to by von Sonnenthal was, that a change in the state of the dissolved tartrates occurred when more water was added to the very dilute solutions; this change was supposed to be of the nature of dissociation. The dilution whereat the change occurred was found to depend on the nature of the metal of the tartrate, and

Vor. IV

tory powers of liquid substances, and of salts in solution. The subject was taken up by Perkin in 1882, since which time a series of memoirs by this investigator has appeared (C. J. 45, 421; 49, 777; 51, 808; 53, 561; 55, 680; 59, 981; 61, 800). The methods employed in the measurements are based on the discovery which Faraday made in 1846 (T. 1846. 1), that most transparent bodies acquire the power of rotating the plane of polarisation of a ray of light when they are brought within the action of a magnet, or of an electric current which is made to pass round the body so that its plane is at right angles to the direction of the ray of light. Faraday showed that the amount of rotation is proportional to the strength of the current, or the intensity of the magnetic action, and to the length of the laver through which the light passes, and that it is dependent on the temperature and on the nature of the substance examined. Perkin has worked with liquid compounds and with solutions. The fluid to be examined was placed in a glass tube about 103 mm. long. and 9 mm. diameter, the ends of which were closed by circles of glass cemented on; the ends of the tube were let into

the pole-pieces of a large electro-magnet. Sodium light was employed by Perkin. (For a description of the apparatus, and the various precautions and corrections, v. Perkin, C. J. 45, 421-445.) Perkin calculates his results so that the observed rotations of liquid compounds are referred to lengths of the liquids related to one another in the same proportion as the molecular weights of the gaseous compounds obtained by vapourising the liquids; the results when thus calculated represent the magnetic rotatory powers of quantities of the various-compounds proportional to the weights of the gaseous molecules of these compounds.

The molecular rotation of water is taken as unity. If r is the rotation of unit-length of liquid, and r' is the rotation of the same length of

water under the same conditions, then γ is the specific rotation of the liquid; and

sp. rot. $\times \frac{\mathbf{M}}{\mathbf{M'} \cdot \mathbf{d}}$ is the molecular rotation, where $\begin{vmatrix} \text{series.} & \text{Per} \\ 45, 574 \end{vmatrix} : -$

is not constant; the change from a normal paraffin, CH_nCH_CH_, to the next higher isoparaffin, CH(CH_), nCH_nCH_, CH_n, raises Mol. R. by 1.023 + .105; in the change from a normal acid to the next higher iso-acid of the same series, CH_has a different value; and so on. When Cl is substituted for H in a hydrocarbon the mol. rotatory power increases, but each Cl atom has a different value from the others. So with the replacement of H in a hydrocarbon by OH; each OH group has its own value, the effect on Mol. R. of the second OH being less than that of the first. So again with the group NO₃; the second NO₃ does not increase Mol. R. so much as the first.

The molecular rotatory powers of various homologous series of carbon compounds may be expressed by the general formula

(Mol. R.) = $c + nI \cdot 023$, where n = number of atoms of C in the molecule of any stated compound in the series, and c is a constant for each series. Perkin gives the following table (C. J. 45, 574):—

M = molecular weight of substance, M' = molecular weight of water, and d = relative density of substance. The calculation may be expressed by

one equation, thus: (Mol. R.) =
$$\frac{r \cdot M}{r' \cdot M' \cdot d}$$

About 200 compounds have been examined by Perkin, the observation of r being repeated five to ten times for each compound, and the specific gravity of each being determined with great care

Magnetic molecular rotatory powers of liquid carbon compounds. In strictly homologous normal series of carbon compounds, each increment of CH, produces a constant increase in molecular rotatory power, amounting to 1023. But when the addition of CH, is accompanied by a change in the distribution of the atomic interactions the change of Mol. R.

These results indicate that the molecular rotatory power of a liquid carbon compound is not the sum of certain constant values belonging to each atom or atomic group, but that it depends, to some extent, on the arrangement of the atoms which form the molecule. This result is confirmed by the outcome of attempts to assign values to the atomic rotatory powers of oxygen and carbon. The following data are given as examples of such attempts.

The atomic rotatory power of hydrogen may be deduced thus:

- 1. Mol. R. $C_nH_{2n+2} = Mol.$ R. $nCH_2 + H_2$; but Mol. R. $nCH_2 = n1.023$.
- The value thus deduced for At. B. of H = 254.
- 2. Mol. R. C_nH_{2n+2} minus Mol. R. $C_nH_{2n+3} = At$. R. of H.

Thus, Mol. R. C.H. = 8.577

Mol. R. C.H. = 3.323 = Mol. R. C.H. At. R. of H = .254

Now, At. R. of C = Mol. R. CH, minus At. R. of $H \times 2 = 1.023 - .508 = .515$.

By applying similar methods to the data for compounds of O, the following results are obtained:

The At. R. of Cl varies according to the series of compounds considered, and also as one or two atoms of II are replaced by one or two atoms of Cl, according as the H replaced is in one part of the molecule or in another part, and so on. Two values are obtained for At. R. of N, according as the atom of N is directly connected with 3 or 5 other atoms or groups. The general conclusion is that changes in the magnetic molecular rotatory powers of liquid carbon compounds are intimately connected with changes in molecular structure, so that any cause which alters this structure also alters the rotatory power.

In C. J. 61, 800, Perkin gives an elaborate study of the constitution of ethyl acetoacetate and allied compounds, which elucidates very clearly the connections between the constitution and the magnetic rotatory powers of carbon compounds.

Mol. R. of compounds in presence of water. Perkin has used determinations of Mol. R. of certain compounds before and after addition of water, to throw light on the question whether hydrates are formed by the action of water on these compounds (C. J. 49,777; 51,808; 55,680). In all measurements of Mol. R. the molecular rotatory power of water is taken as unity; if therefore a compound is formed by the Addition of water to another compound, the Mol. R. of the new compound might be expected to be nearly equal to that of the original compound, plus one unit for each molecule of water added; if the observed Mol. R. is distinctly less than that calculated in this way, the difference may be explained by supposing that the formation of the new compound has been accompanied by a rearrangement of the atoms of the reacting moleoules.

The following are examples of the application of this method. In each case the compound and

formic, acetic, and propionic acids in the ratio of equal molecules of water and acid, either a hydrate or a mixture is formed in each case; but that when H.,SO, and H.O react in about the ratio H.,SO,:H.O (or a little more H.O than this), a rearrangement of atoms occurs with formation of a new compound of S, O, and H (perhaps SO(OH),); and that reactions of this nature, involving rearrangements of atoms, also occur between HNO, and H2O, and CCl2.CHO and H.O.

The following data are interpreted by Perkin to mean that a solution of NH, in water, or in alcohol, 'simply consists of the solvent and ammonia':

$$\begin{array}{ccccc} \text{Mol. R. NII}_{J} + 2 \cdot 11\text{H}_{2}\text{O} = 3 \cdot 91 \\ & 2 \cdot 11\text{H}_{2}\text{O} = 2 \cdot 1 \\ & \text{NII}_{2} & 1 \cdot 81 \\ \\ \text{Mol. R. NII}_{J} + 2 \cdot 18\text{C}_{2}\text{H}_{4}\text{O} = 7 \cdot 886 \\ & 2 \cdot 18\text{C}_{2}\text{H}_{4}\text{O} - 6 \cdot 06 \\ & \cdot & 1 \cdot 826 \end{array}$$

Mol. R. of acids and salts in aqueous solu-tions. Perkin (C. J. 55, 680; 59, 981) gives Mol. R. for HCl as 2:187. This is arrived at by finding values for At. R. of H and Cl from observations of Mol. R. of various chlorides of alcoholic radicles. By similar methods of cal-culation values for Mol. R. of HBr and HI were obtained. The three results are:

The value for HCl was confirmed by measuring Mol. R. of HCl dissolved in isoamyl oxide; the result was Mol. R. HCl = 2.24.

Values were then obtained for the three soids in aqueous solutions. The numbers increased as dilution increased; in any case they were much larger than the values obtained by the method stated above. The following table gives the minimum and maximum values for each acid:

Mol. R. in aqueous solutions.	Maximum.	Minimum.
HCl	4.419	4.045
(15.63 p.c. HCl)	(41.7 p.c. HCl)
HBr	8.519	7.669
(15·47 p.c. HBr)	(65.99 p.c. HBr)
ш	18:451	17.769
	(31·77 p.c. HI)	(67·02 p.c. HI)

Compound and water	Mol. R. observed	Mol. R. calculated for	Diff.
HCO,H.H.O CH,CO,H.H.O C,H,CO,H.H.O H.SO,H,O H.SO,2H,O H,SO,3H.O HNO,2-67H.O CCI,CHO.H.O	2:666 3:554 4:512 3:188 4:113 5:064 8:656 7:037	H.CO,H+1=2:671 CH,CO ₂ H+1=3:525 C ₂ H,CO ₄ H+1=4*462 H ₂ SO ₄ +1=3:315 H ₂ SO ₄ +2=5:188 H.SO ₄ +3=6:188 HNO ₃ +2:67=3:85 CCI_CHO+1=7:591	- ·005 + ·029 + ·05 - ·127 -1·076 -1·124 - ·194

water were mixed in the ratio shown by the formula given, and the Mol. R. of the product was determined; the Mol. R. of the product was then calculated by adding one unit for each molecule H.O to the observed Mol. R. of the original compound without water.

It is evident that the magnetic mol. rotatory powers of HCl, HBr, and HI in aqueous solutions are much greater than the values calculated from those obtained for the same three acids from observations made with compounds of them with C and H; in the case of HCl, the Perkin thinks that when water is added to value of Mol. R. in aqueous solution is much

greater than the value for the same compound in solution in isoamyl oxide. There must be an action of some kind between water and these three compounds.

It has been shown already that addition of

It has been shown already that addition of water to H₂SO₄ results in a value for the Mol. R. of the acid different from that observed for the pure acid itself; but in this case addition of water reduces the Mol. R. of the acid. A similar reducing effect was noticed as accompanying the addition of water to HNO₃.

Perkin was unable to explain these results. Ostwald, however, has shown that they are in keeping with the electrolytic dissociation hypothesis (C. J. 59, 198). According to this hypothesis strong acids are dissociated in aqueous solutions into their ions. Aqueous solutions of

HCl, HBr, and HI, contain the ions H and Cl,

H and Br, and H and I, each with its electric charge. The observed rotatory powers of these solutions, minus the value for the water contained in them, therefore represent the rotatory powers of these ions, and not of the compounds themselves; and the rotatory powers of these ions are considerably greater than those of the non-dissociated compounds. An aqueous solution of H₂SO₄, or HNO₂, must also contain dissociated, electrically charged, ions—according to the hypothesis; but Perkin's observations (ante, p. 259) show that the rotatory powers of the ions of these acids are slightly smaller than those of the acids themselves.

Now, the hypothesis of electrolytic dissociation asserts that the metallic salts of acids are dissociated into electrically charged ions in dilute aqueous solutions; hence determinations of Mol. R. for aqueous solutions of metallic salts of HCl, HBr, HI, H₂SO₄, and HNO₂ ought to give results different from the values obtained for these salts themselves. But the values obtained for aqueous solutions of salts of HCl, HBr, and HI ought, on the whole, to be greater than the calculated values, whereas the values obtained for salts of H₂SO₄ and HNO₄ ought, generally, to be slightly smaller than the calculated values. This deduction is partly confirmed by Perkin's results.

The values of Mol. R. for NH,Cl is calculated by Perkin as follows (C. J. 55, 743). The value for HCl is found from determinations of Mol. R. of alcoholic chlorides, which enable values to be found for H and Cl in combination; the value for NH, is taken as 1.818, which is the mean of the values found from observations on NH, in water and alcohol (ante, p. 259); the sum of the values for HCl and NH₃, with the subtraction of 5, gives the calculated Mol. R. of NH₄Cl. The number .5 is taken from the sum of the values for HCl and NH, because observation has shown that this is about the difference between the values for N^{III} and N^v, and in NH, the N atom is trivalent, while in NH,Cl it is supposed to be pentavalent. The values for the other salts of NH, are calculated in a similar way. Perkin's results for Mol. R. of NH,I, NH,Br, and NH,I show that practically the same values are obtained for solutions containing from c. 80 to c. 60 p.c. of the salts. The results with the six salts were as follows:

	Calculated	Observed, in aqueous solu- tions	Differences
NH,Cl	4·305	6·096	+1.791
NH,Br	6·096	7·997	+1.901
NH,I	8·149	9·896	+1.747
NH,NO,	2·298	2·320	+ .022
NH,HSO,	3·433	3·455	+ .022
(NH,)2SO,	4·551	4·980	+ .439

With regard to NH, NO, and the two sulphates, it is to be observed that the calculated values are found by adding the values for the acid and the base (NH3), then deducting 5 for the change of NIII to Nv, and then deducting 2 for the change from the free acid and base to the combination of these compounds; now, 5 is merely an approximate value for the change from N^{III} to N^V, and 2 is also merely a rough approximation for the value of the process of combination of acid and base. As the differences between the observed and calculated values for NH,Cl, NH, Br, and NH, I are large, small errors in the method of calculating Mol. R. for these compounds do not materially affect the differences in question; but as the differences are small in the cases of the nitrate and sulphates, small errors in the method of calculating Mol. R. for these compounds do materially affect those differences. Moreover, the observations of Mol. R. of the nitrate and the sulphates of ammonium in aqueous solutions were made with a single solution in each case (59.7 p.c. NH, NO₃, 66.6 p.c. NH, HSO₄, and 40 p.c. (NH₄)₂SO₄); hence it is not certain that the numbers set down as the values of Mol. R. of these compounds in aqueous solutions are the true values.

Perkin has also (C. J. 59, 981) made measurements of the magnetic mol. rotatory powers of the ammonium salts of formic, acetic, and propionic acids in aqueous solutions, and compared the results with the values calculated. He gives the results as follows:

	Observed, in aqueous solution	Calcu- lated	Dif- ferences
Ammonium formate ,, acetate ,, propionate	3·363	3·489	- ·126
	4·247	4·343	- ·096
	5·259	5·280	- ·021

The interpretation which the electrolytic dissociation hypothesis gives of these results is that, as in their aqueous solutions the salts examined are dissociated into their ions, and as the observed results are smaller than the calculated values, therefore the magnetic mol. rotations of the ions of HCO₂H, OH₂CO₂H, and C₂H₃CO₂H are slightly less than the rotations of the acids themselves (v. Ostwald, Z. P. C. 9, 513; cf. Ostwald, C. J. 59, 201).

But it seems to me that the numbers given by Perkin as the calculated values of Mol. R. for the three salts cannot be accepted as correct. For these values were found by adding the values of Mol. R. for the free acids to the value for free NH_a ; no deduction was made for the change of rotation accompanying the combination of the acid and the base, and no deduction was made | for the change of NIII to Nv. Either these values cannot be accepted as the true values, or the values calculated for the salts of NH, with the halogen acids, and with HNO, and H.SO., are not correct (ante, p. 260). If the values of Mol. R. for the salts of formic acid &c. are calculated by the same method as was used in the cases of the other salts of ammonium, then the results of this investigation are as follows:

	Observed in aqueous solution	Calcu- lated	Dif- ferences
Ammonium formate ,, acetate ,, propionate	3·363	2·789	+ ·574
	4·247	3·643	+ ·601
	5·259	4·580	+ ·679

If these results are accepted, then the differences are much greater than those given by Perkin, and they are in the opposite direction.

Measurements of the Mol. R. of formic, acetic, and propionic acid in aqueous solution would enable the question to be settled as to the effect of water on these acids; at present it seems that the magnetic rotations of the ions of these acids would be found to be greater than the rotations of the acids themselves.

This conclusion is confirmed by combining the results obtained by Perkin (C. J. 59, 986) for Mol. R. of sodium salts of formic and other acids with the value calculated by him for sodium (C. J. Proc. 1890, 141). In the following table I have calculated the values for the salts as Perkin calculated the values for NII, Cl, NH, NO, &c., by deducting 2 from the sum of Mol. R. of acid and At. R. of Na, and then further deducting .254 for the loss of H:

		Observed in aque- ous solu- tion	Calcu- lated	Differ- ences
Sodium formate .	•	2.347	1.775	+ .572
" acetate .	•		2.629	+ .652
" propionate		4.308	3.566	+.742
" butyrate.		5.332	4.576	+ .756

In a more recent communication (C. J. 63, 57) Perkin gives the Mol. R.s of aqueous solutions of H,SO, HNO, Na,SO, and Lino, of varying degrees of concentration. His results show that the Mol. R.s of these solutions do not vary with dilution in the same way as the electrical conductivities vary. The most dilute solution of H2SO, examined by P. contained c. 9.2 p.c. H₂SO₄, and the most dilute solution of HNO₃ contained c. 22·5 p.c. HNO₃. Now it has been shown repeatedly, by Ostwald and others, that measurements of the conductivities of fairly conc. solutions of acids and salts cannot lead to just conclusions regarding the amount of electrolytic dissociation of the compounds in solution; hence it is not to be expected that the amount of dissociation of H.SO, and HNO, should be calculable from the Mol. R.s of these compounds as deduced from observations on solutions so concentrated as those used by Perkin. What the observations of P. show is that the magnetic rotations of certain compounds diverge from the calcu-

lated results in all cases wherein electrolytic dissociation occurs. The laws which express the electric dissociation of compounds are to be deduced from the study of very dilute solutions. and as no measurements of magnetic rotations have yet been made for such solutions, it is not justifiable to draw detailed quantitative conclusions concerning the electrolytic dissociations of compounds from the measurements of the magnetic rotations of those compounds which P. M. M. P. M. has made.

XI. THERMAL METHODS. Determinations of the quantities of heat which are produced, or which disappear, in chemical reactions help to elucidate the nature of these reactions. There are two sides to every chemical operation; there is a change in the form or distribution of matter, and a change in the form or distribution of energy. Light is thrown on the second of these changes by thermo-chemical investigations, and the connections between the two parts of the complete occurrence, and the mutual dependence of both, are thus made clearer. Thermo-chemical methods rest on the principle of the conservation of energy. When a chemical reaction occurs, heat may be produced, electricity generated, mechanical work done by expansion, and sound or radiant heat may leave the system; the sum of these forms of energy, added to the energy remaining in the system at the close of the reaction, must equal the energy originally present in the system at the moment when the change began. As a large part of the energy set free during any chemical reaction usually takes the form of heat, it follows that measurements of the heat produced during the reaction must give information regarding the differences between the initial and final energies of the system. The primary aim of thermo-chemical measurements is to determine such energy-differences; the secondary aim is to connect these differences with the differences of composition, constitution, and properties which the reacting systems undergo.

The loss or gain of energy which accompanies the passage of a system from one defined state to another is independent of any intermediate states through which the system may pass. This generalisation was proved experimentally for several cases, so far as heat energy was concerned, by Hess in 1840 (P. 50, 885); the generalisation may be deduced from the principles of energy. On this statement rest the methods for determining the thermal values of chemical changes when these values cannot be observed directly.

Notation used in thermo-chemistry. Thom sen's notation is followed in this DICTIONARY; the formulæ of the reacting substances are taken to represent grams of these substances-thus HCl means 36.5 g. of hydrogen chloride; the formula are inclosed in a square bracket, and the figures representing the number of atoms of each ele-

ment are placed above the symbols; the reacting substances are separated by a comma. The unit of heat is that quantity which raises the temperature of 1 g. of water at c. 18° through 1°. Ostwald, in his Lehrbuch der Allgemeinen Chemie, employs a unit almost exactly 100 times greater than this, viz. the quantity of heat given out by 1 g. of water in cooling from 100° to 0°. The symbol Aq means that a large quantity of water is present. Thus [H,Cl] = 22,000 means that 22,000 gram-units of heat are produced when 1 g. H combines with 35.5 g. Cl; [H,Cl,Aq] = 30,660 means that 30,660 gramunits of heat are produced when 1 g. of H combines with 35.5 g. of Cl in presence of a large quantity of water in which the HCl dissolves; [HCl,Aq] = 17,320 means that 17,320 gramunits of heat are produced when 36.5 g. of HCl dissolve in a large quantity of water; and [HClAq,KOHAq] = 13,750 means that the neutralisation of 36 5 g. HCl, dissolved in much water, by 56 g. KOH, dissolved in much water, the products of neutralisation being allowed to remain in solution, is accompanied by the production of 18,750 gram-units of heat. The symbol H.O is used as in ordinary notation to represent 18 g. of water; thus [As O,3HO] = 6,800 means that 6,800 gram-units of heat are produced during the formation of 284 g. H₂AsO₄ by the combination of 230 g. As₂O₅ with 54 g. water; and $[As^2O^3.3H_*O,Aq] = -800$ means that 800 gram-units of heat disappear during the solution of 284 g. H, AsO, in a large quantity of water. Thomsen's notation does not indicate the products of the reaction, the thermal value of which is set down; nor does it show the physical states of the reacting substances, or of the products of the reaction, except in the one case when the substances are dissolved in much water. Ostwald (Lehrbuch) uses the ordinary notation, and adds figures to express the quantities of heat which are produced or disappear in the reactions; he employs ordinary type for liquids, thick type for solids, and italies for gases. Thus, $H_2 + Cl_2 = 2IICl + 44,000$ means gases. Thus, $H_2 + Cl_2 = 2HCl + 44,000$ means that 44,000 gram-units of heat are produced when 2 g. gaseous hydrogen combine with 2 x 35.5 g. gaseous chlorine to form 2 x 36.5 g. gaseous hydrogen chloride; $2H_2S + 2I_2$ = 4HI + 2S - 34,000 means that 34,000 gram- $2H_2S + 2I_2$ gaseous units of heat disappear when 2×34 g. gaseous hydrogen sulphide react with 2×254 g. solid iodine to form 4×128 g. gaseous hydrogen iodide and 2 × 32g. solid sulphur; and 2H2SAq + 2I2Aq = 4HIAq + 2S + 34,000 means that 34,000 gram. units of heat are produced when 2 × 34 g. hydrogen sulphide dissolved in much water react with 2 × 254 g. iodine dissolved in much water, to form a dilute aqueous solution of 4 x 128 g. hydrogen iodide, and 2×32 g. solid sulphur. Ostwald sometimes indicates the temperature by figures in brackets placed after the formula of the substances: thus, $H_2O_{(0)} = H_2O_{(0)} + 1440$ means that

1440 gram-units of heat are produced when 18 g. liquid water at 0° become 18 g. solid water at the same temperature.

Measurements of thermal values of chemical changes. The quantities of heat produced during shemical processes are measured by causing the processes to take place in vessels arranged so it is known at another temperature, s. 72.1, 60-72. changes. The quantities of heat produced during

that the whole of the heat is used in raising the temperature of known masses of water, or of water and a solution the specific heat of which is known. When the process consists in a reaction between substances in aqueous solutions, the calorimeter employed usually consists of a vessel of platinum holding 500 to 1000 c.c. placed inside another vessel of silver, or thin sheet iron, with water between the two vessels. The reacting liquids are brought to the same temperature, and are then mixed in the platinum vessel, and the rise of temperature of the contents of this vessel is noted, any change in the temperature of the outside water being also measured. When the thermal value of a process of combustion is to be determined, the combustion is caused to proceed in a vessel, usually made or platinum, surrounded by a determinate quantity of water; if the products of combustion are gases, an apparatus is attached wherein these gases are absorbed, and thus the quantity of substance burnt is. determined.1

To calculate the thermal value of a reaction. it is necessary to know the initial temperatures of the reacting bodies, the final temperatures of the products of reaction, the masses of the reacting substances, the specific heat of water, the specific heat of the liquid formed by the reaction if the reaction be one wherein a solution is produced, and the water-equivalent of the calorimeter. The water equivalent of the calorimeter must be determined; it is equal to the number of unitweights of water which would be raised to the same temperature as that to which the calorimeter and its accessories-thermometer, stirrer, &c .- are raised by the heat produced in the process. When dilute solutions of acids and alkalis, or similar compounds, react, the specific heat of the dilute salt-solutions produced may be taken as equal- to the specific heat of the water they contain, without appreciable errors.

Let Q be the quantity of heat produced in a reaction between two solutions; let t be the initial temperature of one solution, t' the initial temperature of the other solution, and T the final temperature of the solution produced; further, let a be the calorimetric equivalent of one solution, i.e. mass x spec. heat, b the calorimetric equivalent of the other solution, and c the water-equivalent of the calorimeter; then

Q = (T - t)a + (T - t')(b + c).In the cases of dilute aqueous solutions, a and b represent the masses of water in the solutions mixed. If a change occurs in the state of aggregation of some of the constituents of the reacting system, e.g. if liquid water is formed from gaseous hydrogen and oxygen, the quantity of heat which is produced or disappears in this change must be taken into account in the calculation of the thermal value of the reaction. If contraction or expansion occurs, without change of state, the thermal value of such contraction or expansion must be determined and allowed for.3

Heats of combustion, and of formation, of compounds. The heat of combustion of an element or compound is the thermal value of the reaction which takes place when that element or com-

pound is completely oxidised to those masses of the product, or products, of exidation which are represented by the formulæ of these products. Thus $[H^2,O] = 68,360$; [CO,O] = 67,960. In this Dic-TIONARY the quantities represented by formulæ are taken in grams.

The heat of formation of a compound is the thermal value of the reaction whereby the formula-weight of the compound is produced from the formula-weights of its constituents. Thus, the heat of formation of ILSO, varies according to the constituents from which it is produced; we have the following statements: [SO3,HO] = 21,320; $[SO^2,O,H^2O] = 53,480$; $[SO^2,O^2,H^2] = 121,840$; $[S,O^3,H^2O] = 124,560$; $[S,O^1,H^2]$ = 192.920.

It is often practicable to measure heats of combustion directly; but in very many cases it

[KOHAq,HClAq] = -[K,O,H,Aq] - [H,Cl,Aq] + [K,Cl,Aq] + [H,H,O,Aq];

is necessary to determine heats of formation by indirect methods. These indirect methods rest on the principle, deduced from the laws of energy, that the total change of energy, and therefore the total thermal change, which accompanies the passage of any system from a definite initial composition to a definite final composition is independent of the intermediate states. Suppose that a system changes from a certain arrangement or configuration A to another configuration B, and that x units of heat are produced in this change. Suppose also that the same initial system then passes from the state A to a new state a, from that to b, from that to c, and, lastly, from that to B, and that there are x' units of heat produced in the first of those intermediate changes, x" units produced in the second, and x" units in the third; then x - (x' + x'' + x''') gives the thermal value of the change from the state c to the state B. If then the thermal value of a chemical process, whether the formation of a compound, or other process, cannot be determined by direct measurement, it may be determined if the process can be made a portion of a series of changes, the total thermal value of which is measurable, and the thermal values of all the portions of which are measurable with the exception of the value of that portion which is sought.

For instance, formic acid, CH,O; cannot be directly produced from C, H, and O, and, therefore, the heat of formation of this acid cannot be determined by direct measurement; but C and H can be burnt to CO₂ and H₂O, and CH₁O₂ can also be burnt to CO₂ and H₂O; hence we can acquire the data needed for calculating the value of [C,H²,O²]. The data are these: [C,O²] = 96,960; [H²,O] = 68,360; sum = 165,320; [CH²O²,O] = 65,900. Now, suppose that the first stage of the combustion of C and H, consists in the formation of CII,O2, and that this is then burnt to CO, and H,O, we should have the statement: $[C,O^2] + [H^2,O] = [C,H^2,O^2] + [CH^2O^2,O] = 165,320$. But $[CH^2O^2,O] = 65,900$; and also $[C,O^2] + [H^2,O] - [CH^2O^2,O] = [C,H^2,O^2]$. Hence $[C,H^2,O^2] = 165,320 - 65,900 = 99,420$.

Another example will show the application of the principle to a more complicated case. It is required to find the heat of formation of gaseous hydrogen bromide from gaseous H and Br, i.e. the thermal value of the reaction H + Br = HBr. To begin with: let [H,Br,Aq] = x, and let [H,Br]=x'; direct measurement gives [HBr,Aq] = 19,900. x-19,900=x'=heat of formation of HBr. Hence it is necessary to determine x.

Now, the thermal values of the neutralisation of HClAq and HBrAq respectively by KOHAq are found to be the same, i.e. [KOHAq,HClAq] =[KOllAq,HBrAq]. If these reactions are analysed, the first is seen to consist in (1) the splitting of HClAq into H and Cl in presence of water; (2) the separation of KOHAq into K, O, and H in presence of water; (3) the combination of K and Cl, in presence of water, to form KClAq; (4) the combination of II, H, and O, in presence of water, to form water; and the second is similar to this, only putting Br in place of Cl. These reactions may be stated in thermo-chemical notation thus:

(2) [KOHAq, HBrAq] = -[K, O, H, Aq] - [H, Br, Aq] + [K, Br, Aq] + [H, H, O, Aq].

The first and fourth terms on the right side are the same, and the total thermal values are the same. Are the values of the second and third terms the same? To answer this question we pass Cl into KBrAq, forming KClAq and BrAq, and measure the thermal disturbance; we then analyse the reaction, and see what information it has afforded. These are the results:

[KBrAq,Cl] = 11,500, i.e. -[K,Br,Aq] + [K,Cl,Aq] + [Br,Aq] = 11,500. Now, [Br,Aq] = 500, by direct measurement, [Er,Aq] = [K,Br,Aq] + [K,Cl,Aq] = 11,000, i.e. to form KCl, in solution, from K and Cl produces 11,000

units of heat more than to form KBr, in solution, from K and Br.

Now, turning back to equations (1) and (2) above, and remembering that the thermal values of these are the same, it is evident that, since 11,000 more heat-units are produced in forming KClAq than in forming KBrAq, each from its elements, 11,000 more heat-units must disappear in splitting up HCl, in presence of water. into H and Cl, in presence of water, than in similarly separating HBr into H and Br in presence of water; and therefore, since the heat energy required to decompose a stated mass of a compound is equal to the heat energy that is produced when the same mass of that compound is formed, 11,000 more heat-units will be produced in the formation of HClAq from H, Cl, and Aq than in the formation of HBrAq from H, Br, and Aq; or, stated in thermo-chemical notation: [H,C],Aq]=11,000=[H,Br,Aq]. Now [H,C],Aq]=39,300 by direct measurement, $[H,Br,\Lambda q] = 39,300 - 11,000 = 28,300.$

At the beginning of this calculation we had H.Br.Aq]-19,900 = [H.Br]. We can now substitute the value of [H.Br,Aq], and write [H.Br]=28,300-19,900=8,400. That is to say, 8,400 gram-units of heat are produced when 81 g. gaseous hydrogen bromide are formed from 1 g. gaseous hydrogen and 80 g. gaseous bromine. Exothermic and endothermic reactions. Chemical changes which are accompanied by production of heat are sometimes classed together as exothermic reactions, and are distinguished from changes accompanied by disappearance of heat, which changes are called endothermic reactions. The terms endothermic and exothermic are sometimes useful. It should not be forgotten that most chemical reactions consist of portions which are exothermic and portions which are endothermic. Substances which are formed with the disappearance of heat are generally more readily decomposed by the application of outside forces than substances which are formed with the production of heat.

Interpretation of thermo-chemical measurements. Thermo-chemical measurements aim at determining the quantities of heat which are produced or disappear during definite and defined chemical changes. But every chemical change is inextricably bound up with more or less extensive physical changes; hence some portion of the thermal value of a chemical occurrence is always due to a process which is not, strictly speaking, chemical. A purely chemical change is a change in the distributions, configurations, and motions of atoms. But in only some cases are we able to form clear conceptions as to the configurations and motions of atoms; therefore, even if it were possible always to disentanglethe purely chemical from the accompanying physical parts of a change, we should still very frequently be unable to connect the thermal values of purely chemical processes, in a clear and definite

way, with measurable changes in the distribu-

tions, configurations, and motions of atoms.
The heats of formation of HCl, HBr, and HI
are said to be 22,000, 8,440, and -6,050 gramunits respectively. But these thermal values
are not strictly comparable, because the first represents the heat produced in forming gaseous
HCl from gaseous H and Cl; the second represents the heat produced in forming gaseous HBr
from gaseous H and liquid Br, and the third represents the heat which disappears when gaseous
HI is formed from gaseous H and solid I. In
other words, more heat is used in the second
change than in the first, and still more in the
third than in the second, in accomplishing subsidiary physical changes. Steam is decomposed
by chlorine, with formation of hydrogen chloride
and oxygen. All the reacting substances are
gases. This change, which is stated in formule
as 2H₂O+2Cl₂=4HCl+O₂, when analysed
thermo-chemically, is found to consist of four
parts, thus: [2HO,2Cl²]
= -2(H,H,O)-2[Cl,Cl]+ {O,0}+4[H,Cl],

= -2[H,H,0] -2[OI,CI] +[O,0] +4[H,CI]. We measure the thermal value of this complete change, but we cannot at present separate the portions of the change and assign to each its proper thermal equivalent; hence we cannot give a complete explanation of the thermochemical measurement we have made.

Notwithstanding these difficulties, attempts have been made to generalise from thermochemical measurements to statements of universal applicability. The most widely known of such attempts is that which finds expression in Berthelot's 'law of maximum work.'! This so-called law asserts that 'Every chemical change accomplished without the addition of energy from without tends to the formation of that body, or system of bodies, the production of which is accompanied by the development of the maximum quantity of heat.' In another place Berthelot states the law more rigidly, thus: 'Every chemical change which can be accomplished without

1 Micanique Chimique, L. Exix.

the aid of a preliminary action, or the addition of energy from without the system, necessarily occurs if it is accompanied by disengagement of heat."

The same generalisation was stated by Thomsen (v. Th. 1, 12-16) some years before it was enunciated by Berthelot. Thomsen's statement took this form: 'Every simple or complex reaction of a purely chemical kind is accompanied by production of heat.' None of these statements is strictly applicable to actually occurring chemical changes, because we never have to deal with reactions of a purely chemical kind, but with reactions that are partly chemical and partly physical-that is, with reactions which consist in part in changes in the arrangement and motions of atoms, and partly in changes in the arrangement and motions of molecules. A consideration of the way in which the so-called law is applied, especially by Berthelot and his school, shows that it is taken to mean that measurements of the thermal values of various possible chemical changes enable us to predict which of these will occur. Thus, suppose we start with a system A + B + C, and suppose that from this may be formed AB+C, AC+B, or ABC; suppose also that x thermal units are produced in the first of these changes, x' thermal units in the second, and x" thermal units in the third; finally, suppose that x'' > x' > x; then the law of maximum work is taken as asserting that the reaction A + B + C = ABC will occur, and will occur to the complete, or almost complete, exclusion of the two other possible reactions.

It is easy to show that many reactions are known to occur which would be impossible were this 'law' a true generalisation. But it is better to treat the law as a deduction from the principles of energy, and to show that it is not a warrantable deduction.

The statements made by Thomsen and Berthelot are true only when an arbitrary separation is made of chemical changes into two parts, and one of these parts is alone called chemical. Every chemical change, however simple, consists of at least two parts, the first of which is the necessary antecedent of the second; the 'law of maximum work' ignores this duality, or, it might be more accurate to say, the law assumes that the second part of a chemical process may occur without the first. A process of chemical change may be compared to the flight of a stone from, and its return to, the surface of the earth. During the first part of this process there is a continual transference of kinetic energy from the moving stone to the surrounding medium and during the second part there is a continual transference from the medium to the stone, until the stone comes to rest, when its energy becomes a part of the total energy of the system earth plus stone. If the final resting-place of the stone is nearer the centre of the earth than the spot from which it was projected in its upward flight, then the stone contains less energy, relatively to surrounding systems, at the close of the trans-action than at the beginning. On the other hand, if the starting-point is nearer the earth's centre than the final point of rest, then the transaction has resulted in a gain of energy to the stone. In both cases the second part of the transaction, that which occurs between the turnIng-point and the coming to rest of the stone, is attended with loss of energy to the stone; but this second part does not represent the complete transaction. The 'law of maximum work,' if applicable at all, is applicable only to the second part. And, moreover, this law ignores the fact that the stone, or chemical system, does not leave its initial resting-place of its own accord; the law assumes that no work need be done, no energy need be expended, in the passage of the stone, or chemical system, from its original position to that whereat the energy-relations between it and surrounding systems come within the cognisance of the law.

The 'law of maximum work' asserts a certain condition of equilibrium for a chemical system, for the law states that equilibrium results when that change has occurred which is attended with the maximum production of heat. But the true condition of equilibrium of a material system undergoing a reversible change is laid down in the statement that equilibrium results when the entropy of the system has attained the maximum value under the conditions which prevail.

Let Q = quantity of heat added to a body at constant temperature T, then $\frac{Q}{T}$ = gain of entropy to the body; let Q_1 = quantity of heat lost by a body at constant temperature T_1 , then $\frac{Q_1}{T_1}$ = loss of entropy to the body. All chemical and physical changes which occur spontaneously increase the entropy of the system. This statement holds good for non-reversible changes; and as no actually occurring change is completely reversible, the statement holds for all changes.

Suppose that one of two bodies is lotter than the other and loses heat to the colder body; the hotter body at temperature T_1 loses, heat Q, therefore its entropy is diminished by $\frac{Q}{T_1}$; the colder body at temperature T_2 gains heat Q, therefore its entropy is increased by $\frac{Q}{T_2}$; but as $T_1 > T_2$, it follows that $\frac{Q}{T_1} < \frac{Q}{T_2}$; in other words, the entropy of the system is increased by the passage of heat from the hotter to the colder

body. Now, a system is in equilibrium when its entropy has attained the maximum value possible under the conditions. But, inasmuch as entropy is measured by a quantity of heat divided by a temperature, it is only at the absolute zero of temperature that dS=dQ (S=entropy, Q=quantity of heat); hence it is only at the absolute zero that thermal changes directly measure changes of entropy. When a chemical change is accompanied by the production of much heat, and the change occurs at a low temperature, the thermal change will roughly measure the change of entropy; therefore, if such a change be possible, it will occur. But if the quantity of heat produced in a chemical process is small, the change of entropy may be conditioned, to a large extent, by changes other than the thermal change. Indeed, in some cases, heat may disappear from the system, and yet the total change of entropy may be positive; in such cases, chemical change will occur with the disappearance of heat, because the decrease in the entropy of the system caused by the loss of heat will be more than balanced by the increase in the entropy caused by the changes of state which the system undergoes.

The general conception of chemical change which is given by applying the law of entropy is that of a system attaining equilibrium as the result of processes taking place in opposite directions. According to van't Hoff (Dynamique Chimique, 153), the directions of chemical processes which result in equilibrium vary with variations of temperature in such a way that the lower the temperature the more is equilibrium established with the production of heat, but the changes can take place wholly in one direction only at the absolute zero. The law of maximum work' would then hold good for the limiting case that the changes should occur at -273°. As the temperatures at which most chemical changes occur are not very high, many chemical processes are accompanied by production of heat.

The 'law of maximum work' is not, then, a law of nature. But it is true that most chemical processes which occur without the expenditure of much energy from without, and which take place at moderate temperatures, are accompanied by the disengagement of heat. If it is known that a certain chemical change would be attended by the disappearance of much heat, we may conclude that this change will be difficult to accomplish; that it will be brought about only by the expenditure of a considerable quantity of energy, and that the most successful way of accomplishing the change will be to make it one part of a series of changes the sum of which is attended with the disengagement of heat.

Applications of thermo-chemical methods.
The applications of thermo-chemical methods are many and varied. A few of the more important

will be briefly dealt with here.

Neutralisation of acids and bases. In 1842 Hess stated the principle of the thermo-neutrality of salts in solutions (P. 52, 79). He said that when aqueous solutions of two normal salts are mixed the thermal disturbance is nil; in other words, that the thermal value of the reactions consisting in the exchange of the acids and bases is equal to zero. Hess supposed that the heats of neutralisation of acids were independent of the nature of the bases used. Andrews (P. 54, 208; 59, 428) thought that the heats of neutralisation were dependent only on the bases, and were independent of the nature of the acid employed. Favre a. Silbermann (A. Ch. [3] 34, 357; 36, 1; 37, 406) put the law of thermo-neutrality in its proper form by showing that the differences between the heats of neutralisation of any two bases by any acid have a constant value, and the differences between the heats of neutralisation of two acids by any base are constant. Let the composition of various salts be represented by the scheme :

A" + B A"' + B $\mathbf{A} + \mathbf{B}$ A' + BA"+B' A"+B" A' + B' A' + B" A''' + B' A''' + B'' A + B'A + B" A + B" A' + B"' $\tilde{A}'' + \tilde{B}'''$ $\overline{A'''} + \overline{B'''}$ And let f(A + B), f(A' + B), &c., represent the quantities of heat produced by the union of the acid A with the base B, the acid A' with the base B, &c. Then the law of thermo-neutrality asserts that

$$f(A + B) + f(A' + B') - f(A + B') - f(A' + B) = 0$$
or $f(A + B) - f(A + B') = f(A' + B) - f(A' + B')$
and $f(A + B) - f(A' + B) = f(A + B') - f(A' + B')$

Exceptions have been found to this law, but these exceptions have all proved to be connected with some abnormality in the behaviour of the salts formed. The law may be stated by saying that, in the normal formation of a salt, in solution, by the reaction between an acid and a base, the acid contributes a definite portion of the total heat of neutralisation, independently of the nature of the base, and the base contributes a definite portion of the total heat of neutralisation, independently of the nature of the acid. If the statement is correct, then the heat of neutralisation of an acid, in solution, must be independent of the nature of the base, and the heat of neutralisation of a base, in solution, must be independent of the nature of the acid, unless there be some divergence from the normal condition of affairs. By the heat of neutralisation of an acid is meant the quantity of heat produced when an equivalent weight of the acid reacts with an equivalent weight of a base, both being in dilute aqueous solution. If A' represents a formula-weight of a monobasic acid, A" a formula-weight of a dibasic, and A" a formulaweight of a tribasic, acid; and if B represents a formula-weight of a mono acid base; then the heats of neutralisation of these three acids are the thermal values of the reactions,

[A'Aq,BAq]; [',A''Aq,BAq]; and [',A'''Aq,BAq]. Sometimes it is more convenient to take the thermal values of the reactions [A''Aq,2BAq] and [A'''Aq,3BAq] to represent the heats of neutralisation of the dibasic and tribasic acids respectively.

The following table, taken chiefly from Thomsen's results, shows that the heats of neutralisation of the strong acids are practically independent of the base, provided the base used is strong; the numbers all refer to reactions between dilute solutions of the acids and bases:—

Acid	NH,	NMe,	NH,OH	
HCl HNO _s	12,200 12,300	8,700	9,200	

When weak acids neutralise strong bases, the thermal values differ from those obtained for strong acids; and when weak acids neutralise weak bases the reactions have different values from any of the preceding cases. The following numbers illustrate this:

Acid	NaOH strong	NH, weak base	
₹ { CO₂Aq	10,100	10,900	8,400
	7,700	7,800	6,200

The electrolytic dissociation hypothesis gives an explanation of the facts concerning the thermo-chemical reactions between acids and bases. According to this hypothesis, a dilute aqueous solution of a salt contains the ions of the salt each with its electric charge; the salt is dissociated into its ions; when two dilute salt solutions are mixed, the ions remain as they were, there is no change, and therefore heat is neither produced nor consumed. The law of thermo-neutrality holds. The hypothesis looks on a dilute aqueous solution of a strong acid, or a strong base, as containing the ions of the acid or the ions of the base; when the solutions of the strong acid and strong base are mixed, a salt is not formed in the solution, because in dilute solutions salts are wholly dissociated, but water is formed by the union of the ion H of the acid with the ion OH of the base. Thus, the composition of dilute solutions of HCl and NaOH. before and after mixing, are represented by the hypothesis as follows:

Acid	NaOH	кон	Lioit	TIOII	BaO,H,	łСаО.Н,	lSrO,Π,	Pt(NH ₃),(OH),	S(C,H,),OH	N(CH,)OH
HCI	13,300	13,300	13,300	13,300	13,300	13,300	13,300	13,600	13,700	13,600
HBr HI	13,300	13,300 13,300	-	-			-	=	=	=
HNO. HClO.	13,500 13,600	13,500 13,600	=	13,500	14,000 14,000	13,900	-	=	=	=
HBrO. HIO. HOIO.	13,600 13,600	13,600 13,600	=	=	=	=	_	_	=	=
HOIO.	14,000 13,500	14,000	_	=	13,800	=	_	=	=	=
H.S.O. H.PtCl. H.O.H.SO.	13,600 13,500	=	=	=	13,600	=	_	_	=	

If concentrated solutions are employed, the heats of neutralisation, even of the strong acids, show considerable differences with different bases. If the salt which is formed by neutralising an acid by a base is allowed to precipitate, then the apparent heat of neutralisation as thus determined is not the true heat of neutralisation (v. Th. 1, 440). The following numbers represent the heats of neutralisation of two strong acids by weak bases; these numbers differ from one another, and also from the values given in the preceding tables in which strong acids and strong bases only were included;

Or, generally, if M represent the positive ion of a strong base, and A the negative ion of a strong acid; we have the composition of the dilute aqueous solutions, before and after mixing, ropresented by the two schemes:

$$M + OH + H + A$$
 and $M + A + HOH$

Hence, as the only process wherein heat can be produced consists in all cases in the union of H with OH, the quantity of heat produced is always the same. The hypothesis asserts that HOH is produced because water is a non-dissociable, or nearly a non-dissociable, compound; pure water is, approximately, a non-electrolyte.

But when a weak acid is mixed, in dilute aqueous solution, with a strong base, or when dilute solutions of a weak acid and a weak base are mixed, the processes are more complex; for, according to the hypothesis, only a portion of the weak acid is dissociated into ions, and only a portion of the base is dissociated if the base is weak. In such cases the state of matters, before and after mixing, would be represented thus (supposing both acid and base to be weak)—

$$\frac{\text{HA} + \overset{+}{\text{H}} + \overset{-}{\text{A}} + \text{MOH} + \overset{+}{\text{M}} + \text{OH}}{\text{before inixing}}$$
and
$$\frac{\text{HA} + \text{MOH} + \overset{+}{\text{M}} + \overset{+}{\text{A}} + \text{HOH}}{\text{after mixing}}$$

But the process does not necessarily stop here; there is a striving towards the formation of the comparatively non-electrolytic compound HOH, therefore more of the acid and more of the base become dissociated, so that we have, as a final condition, less or more of the acid HA, and less or more of the base MOH, remaining in the solution. The dissociation of the acid and the base, when these are mixed, is accompanied by a thermal change; and as the degree to which this dissociation proceeds depends on the nature of the acid and the base, the values of the heats of neutralisation of weak acids and weak bases differ one from another (cf. Electrical Methods, p. 189 in this vol.).

If this treatment of the heats of neutralisation of acids and bases is accepted, it is evident that the thermal values of the neutralisations of acids by a base do not necessarily measure the affinities of these acids for that base. If the acids were all equally dissociated in solution, they would all be equally strongor their affinities would be equal-and their heats of neutralisation would be equal. The statement Q = about 13,500 + A + B expresses the heat of neutralisation of any acid by any base in dilute aqueous solution. A represents the heat of dissociation of the acid, and B is the heat of dissociation of the base, into their ions; A and B may be positive or negative at any specified temperature. Under the conditions of the experiment only a portion of the acid, or of the base, may be dissociated; therefore the observed heat of neutralisation cannot measure the affinity of the acid for the base. But at the same time, it is evident that there is a connection bctween the heats of neutralisation and the affinities of acids and bases. On the one hand, measurements of the thermal values of the reactions between acids and bases enable conclusions to be drawn as to the distribution of two acids between one base, or two bases between one acid, and such measurements therefore lead to determinations of the affinities of acids and bases (v. infra); on the other hand, although the affinity of an acid for a base probably consists in a striving towards electrical equilibrium among the ions, yet, as electrical and thermal phenomens are closely connected, measurements of the heats of dissociation of acids and bases, in aqueous solutions, must help us to understand the relative affinities of acids and bases, to classify acids and bases in accordance with their affinities, and to connect the affinities of these substances with their constitution (cf. Electrical Methods), especially pp. 208 and 209).

Monobasic and polybasic acids. When an equivalent of a monobasic acid is added to an equivalent of a base, both in dilute solutions, a certain quantity of heat is produced, and there is no further thesmal disturbance on adding more of the acid to the neutral solution; but heat is either produced or disappears when a polybasic acid is added to a solution of the same acid which has been neutralised by an equivalent quantity of a base. This behaviour enables a thermo-chemical distinction to be drawn between monobasic and polybasic acids (cf. Actus, Basicity or, yel. i. p. 51).

Basicity or, vol. i. p. 51).

Distribution of an acid between two bases.

Thomsen found the following data:

[H²SO¹Aq,2NaOHAq] = 31,380; [2HNO³Aq,2NaOHAq] = 27,230;

 $[Na^2SO^4Aq, 2HNO_3Aq] = -8,500.$ Now, supposing that the reaction of equivalent quantities of Na₂SO₁ and HNO₃, in dilute solution, produced NaNO, and H.SO,, and these compounds only, this reaction would be attended by the disappearance of 31,380 - 27,230 = 4.150 thermal units; but as only 3,500 thermal units disappear in the reaction, it is evident that some change has occurred wherein heat has been produced, or that the whole of the Na SO, has not been changed to NaNO, by the reaction of the equivalent quantity of HNO,. If we suppose that the discrepancy in the quantity of heat consumed is due to the partial decomposition of the Na SO₄ by the IINO₃; in other words, if we suppose that when equivalent quantities of Na SO, and HNO, react in solution, some of the base remains united with the II,SO, and some goes into combination with the HNO, and that no other reaction occurs, it is easy to calculate the distribution of the base between the two acids. For it is evident that, on this supposition, 8500 4150 = 845 of the quantity of Na_zSO₄ present

statement $[nH^*SO^*Aq, Na^*SO^*Aq]$ = 31,380 - $\frac{n}{n+8}$ 3,300. These data give a means for calculating the distribution of the base between the two acids. The complete reaction between equivalent quantities of Na,8O, and HNO, will consist of three parts: (1) the decomposition of a equivalents of Na,8O, attended with the disappears of a. 31,380 thermal units; (2) the formation of a equivalents of NaNO, attended with the production of a. 27,230 units of heat; (3) the reaction of a equivalents of H,SO, with 1-a equivalents of Na,SO, attended with the disappearance of

has been decomposed. Thomsen found that II,SO, reacts with Na,SO, to form NaHSO, with disappearance of heat. He also found that this

reaction is expressed thermo-chemically by the

led with the disappearance of
$$1-a = \frac{\frac{a}{1-a}}{1-a} 8,800 \text{ units of heat.}$$

The complete thermo-chemical change may be stated thus:

[Na²SO¹Aq,2HNO¹Aq] = -3,500
=
$$a(27,230-31,380)-(1-a)$$
 $\frac{a}{1-a}$ 3,300.
 $\frac{a}{1-a}$ + '8

Thomsen found that if a is taken as $\frac{2}{3}$, the number - 3550 is obtained, which is almost identical with the observed value. Hence Thomson concluded that $\frac{3}{3}$ of the base, NaOH, went to the nitric acid, and $\frac{1}{3}$ to the sulphuric acid; or, that the affinity of nitric acid for soda (Thomsen used the term avidity) is twice as great as the affinity of sulphuric acid for the same base.

The relative affinities of various acids for different bases have been measured by Thomsen by this method (v. Affinity, vol. i. pp. 74-75).

Allotropy and isomerism. The generally

accepted views regarding the allotropy of ele ments and the isomerism of compounds would lead us to expect that the formation of one allotropic form of an element from another form, or the formation of one isomeride from another, should be accompanied by changes of energy, and, therefore, probably by the produc-tion or disappearance of heat. This expectation is confirmed by thermo-chemical measurements. The following tables present some typical data:-

Combustion of allotropic forms of sulphur,

phosphorus, and carbon. [8,0"] to form gaseous SO2 71,220 for S crystallised from CS, 71,720 rhombie S 72,300 native opaque S [P2,O3] to form solid P.O 369,500 ordinary P for 362,800 red P [C,O²] 96,900 to form gaseous CO, amorphous C for 93,200 diamond Combustion of isomeric carbon compounds.

[C'H',O's] to form 6CO, + 3H,O 787,900 for benzene 883,200 dipropargyl [C2H6O,O5] to form 2CO, +3H,O 330,400 ethylic alcohol for 344.200 methylic ether [C⁹H⁴O,O⁸] to form 3CO $_2$ + 3H $_2$ O

allyl alcohol

propaldehyde

acetone

for

442,600

424,000

420,000

These values, and many more might be given, show that the quantity of heat produced in the change from the combination of a certain number of atoms to certain other combinations of these atoms is dependent, in part, on the arrangement of the atoms in the initial combination. Isomeric molecules differ in the arrangements of their parts; and they also differ in the quantities of energy which are associated

with the different atomic arrangements. The attempts which have been made, chiefly by Thomsen (v. Th. vol. iv.), to connect in a definite way the thermal values of the combustion and formation of carbon compounds with

the constitutions of these compounds have not led, as yet, to any very satisfactory results (v. also Armstrong's criticism of some of Thomsen's conclusions; P. M. Feb. 1887. 73).

Dissociation.—This very important branch

of the subject is fully discussed in the article Dissociation in vol. ii. pp. 385-410.

XIII. VISCOSITY OF LIQUIDS. A per fect fluid, if such existed, would offer no resistance to a change of shape, and if its parts were set in motion relatively to each other by the action of any forces, the work done would be exactly equal to the kinetic energy produced. Moreover, this energy of motion would continue unchanged in amount if the fluid were then left to itself, and would not die away by being converted into heat as is the case with every known fluid. The property which causes this subsidence of relative motion is called viscosity. In consequence of the existence of viscosity a continual expenditure of energy is required to maintain the parts of a fluid in a state of steady motion relatively to each other, just as the existence of friction makes it necessary to apply a constant force to a body to keep it moving uniformly over another. From this resemblance in the two

cases the viscosity of a substance is often called its internal friction.

Imagine a layer of a liquid one cm. thick, contained between two flat plates, one of which is at rest and the other is moving parallel to the first. The liquid in contact with the plate which is at rest is at rest also, and the successive layers have velocities which increase uniformly as we go towards the moving plate, so that the liquid is being sheared, and this requires a continual supply of work; which is proportional to the area and velocity of the moving plate. If this velocity is one cm. per second, the coefficient of viscosity is defined as the tangential force which must be applied per sq. cm. to the moving plate to maintain the motion, or if the relative velocity of the two surfaces is v, and their distance apart is l, the tangential force T per unit area required

to maintain the motion is given by $T = \eta_l^v$ where η is the coefficient of viscosity.

From this definition it can be proved that if a circular plate or other solid of revolution be set vibrating about its axis of figure in a liquid, the amplitudes of successive vibrations will bear a constant ratio to each other, and the experimental verification of this is the best proof we have of the proportionality of the viscous forces to the relative velocity of the parts of the fluid.

The coefficient of viscosity is regarded by Maxwell (P. M. [4] 35, 133) as being the product of two factors, a coefficient of elasticity and a If between the parallel time of relaxation. plates spoken of above we have an elastic solid without viscosity, instead of a liquid, the result of moving one of the plates parallel to the other will be to distort the solid, and give rise to a force or stress tending to restore it to its original shape, and this force will be proportional to the amount of distortion and to the coefficient of rigidity of the body. Now, if the body is a viscous substance like pitch, the stress will soon die away, even though the surfaces be held in the new position, the molecules rearranging themselves so that this position becomes one of equilibrium. The time required for this to take place is what Maxwell called the time of relaxation. For solids it may be very large, extending to several hours or even days, but for ordinary liquids it is a small fraction of a second, while for a gas, such as air, Maxwell estimated it at the fifty thousand millionth of a second. The rate at which this internal stress is disappearing at any moment is proportional to the strain at that moment. If the upper surface is moved uniformly, relatively to the lower one, the strain will never disappear entirely, for, although the rearrangement of the molecules is continually going on andthe substance is tending towards its equilibrium state, the strain is being continually set up again by the relative motion of the two surfaces we are considering, and the body will soon get into a steady state in which the rate whereat the strain is being produced is equal to the rate whereat it is dying away. The stress produced by this constant strain is the tangential force required to maintain the motion, and Maxwell proved that this stress is proportional to the coefficient of rigidity of the substance and to the time of relaxation.

For the determination of coefficients of viscosity, Coulomb and others allowed some solid of revolution, such as a circular plate or a sphere immersed in the fluid, to vibrate about its axis of figure, and observed the ratios of the amplitudes of consecutive vibrations, from which the coefficient can be calculated. O. E. Meyer (W. 43, 1) modified the method by hanging a flat cylindrical box by a bifilar suspension, filling it with liquid, and observing the rate at which the vibrations died away. This method has been used by Mitzel (W. 43, 15), and is capable of considerable accuracy. For absolute measurements it has some advantages in the fact that the lengths to be measured are not very small; but in most cases only relative values are required, and for obtaining these the transpiration method described below is preferable, as it is more readily applied, requires a smaller quantity of material, and lends itself better to accurate adjustment of temperature.

In the common form of the experiment the liquid is caused to flow through a capillary tube in consequence of a constant difference of pressure, P. between the ends, and the time, t, is observed which is required for a volume, v, to flow through the tube; then the coefficient of viscosity, η , is given by the equation $\eta = \frac{\pi}{8} \frac{Prt}{lv}$,

where r is the radius and l is the length of the tube. Hence the coefficients for two liquids will be in the ratio of the times required for the outlow of the same volume with the same difference of pressure. If the liquid flows through the tube in consequence of its own weight, P will be proportional to its specific gravity, and the coefficients of viscosity will be proportional to the product of specific gravity and time of flow.

The formula given above assumes that the work done by the pressure is entirely converted into heat inside the tube, or, in other words, that the liquid flows out without any appreciable kinetic energy. If the tube is very long and narrow this may be taken to be the ease, but generally a small correction has to be applied for the energy of the issuing fluid. The form of this correction is doubtful. Hagenbach (P. 109, 385) has given a formula which has been largely used, but Wilberforce (P. M. 1891, 407) has pointed out an error in his assumptions which makes the correction probably too small.

The coefficient of viscosity falls off very rapidly with rise of temperature, the average rate of fall for water between 0° and 10° being nearly 3 p.c. per degree, which shows the necessity for very accurate adjustment of the temperature during an experiment.

Using Maxwell's conception of the nature of viscosity, and making certain assumptions as to the way in which the rigidity and the time of relaxation vary with the temperature, Graetz (W. 24, 25) deduced the formula $\eta = A \frac{t_0 - t}{t - t}$, where

 t_i is some low temperature at which η is infinite, and t_o is the critical temperature. The formula expresses the facts very well over a moderate range, but, as we might as reasonably assume the connection between η and t as between the time of relaxation and t, it can only be regarded as empirical.

Extensive observations of the viscosity-coefficients of organic liquids have been made by Graham (T. 1861), Relistab (Inaug. Diss. Bonn, 1868), Guerout (C. R. 81, 1025; 83, 1291), Pribram a. Handl (Sitz. W. 1878 and 1879), and Gartenmeister (Z. P. C. 6, 524); but few laws have been observed beyond qualitative relations applicable to small classes of compounds. In general the viscosity increases with the molecular weight, but formic acid is an exception, as it is more viscous than acetic acid. Isomeric esters have nearly the same viscosities, that with the higher alcohol radicle having the greater. Normal compounds are generally more viscous than the corresponding iso- compounds, but the propyl halogen compounds, and a few others, form exceptions. At high temperatures these differences are less marked than at lower ones, rise of temperature tending to efface the distinction between normal and iso- compounds. Pribram a. Handl endeavoured to find the conditions of temperature under which the results are comparable; by determining the coefficients of viscosity of a number of liquids at various temperatures up to 50°. Taking the series PrCl, EtBr, PrBr, EtI, and PrI, they plotted the curve connecting vis-cosity with molecular weight, and found that while at the lower temperatures it was distinctly curved it got gradually flatter with rise of temperature, till at 50° it was almost a straight line. showing that at this temperature the increase of viscosity is proportional to the increase of molecular weight, whether this be due to the introduction of CH., or of a halogen.

Though sulphuric acid is much more viscous than water, the first effect of adding water to it is, as Graham showed, to increase its viscosity, and this continues till 18 p.c. of water has been added, when a maximum is reached, and further addition of water causes a rapid diminution of viscosity. The mixture with maximum viscosity corresponds to the proportions given by the formula H2SO, H2O, and there is a maximum in the electrical resistance near the same point. Similar relations are shown by nitric and acetic acids. For mixtures of alcohol and water Graham showed that the particular proportion of the constituents which gives the greatest contraction has maximum viscosity, and Traube (B. 19, 871) showed further that aqueous solutions of most alcohols and acids of the fatty series have maxima which occur at different concentrations according to temperature.

Arrhenius (Z. P. C. 1, 285) has investigated the relation between the concentration of a solution and its viscosity; he finds that for indifferent substances the exponential formula $\eta = A^{1-x}B^x$ expresses the results, where η is the viscosity, x the proportion by volume of the dissolved substance, and 1-x that of the solvent, so that A is the viscosity of the pure solvent, and B is a constant for the dissolved substance which is independent of the concentration up to about 10 p.c. As the solvent is usually water, and its viscosity is taken as the unit in comparative measurements, the formula can be written in the form $\eta = B^z$. In every case investigated by Arrhenius B proved to be greater than unity, showing that the viscosity of water is increased by the addition of a small quantity of an indif-

ferent substance. The same is generally true of salts, but not quite invariably so. A viscous fluid like glycerin has less effect than ether has; there seems, in fact, to be no relation between the value of B and the viscosity of the dissolved substance alone.

The latest and most comprehensive determinations of the viscosities of salt solutions are by Reyher (Z. P. C. 2, 744), Wagner (Z. P. C. 5, 31), and Lauenstein (Z. P. C. 9, 417). The formula of Arrhenius in the form $\eta = \Lambda^x$, where x is now the number of gram-molecules in a litre of solution, or A is the viscosity of a normal solution, is found to hold moderately well, but for many salts of acids of the aromatic series it shows divergences if the strengths of the solutions are greater than half normal.

Wagner worked with sulphates, nitrates, and chlorides of metals, and found that the viscosities of solutions of equivalent quantities of the various salts are additive quantities, the part which the base or the acid contributes being approximately constant. A further relation is shown by table lating the viscosities of normal solutions of the chlorides arranged according to the periodic law, when the coefficients are found to diminish in any group as the molecular weight increases. From this arrangement it would seem that copper and manganese should be put in the eighth group, for their coefficients are almost exactly equal to those of nickel and cobalt.

Reyher determined the viscosities of a number of acids and their sodium salts, and found they could be divided into two classes. The strong mineral acids have viscosities about 3 p.c. less than those of the sodium salts, while the weaker mineral acids and organic acids have coefficients from 20 to 30 p.c. less.

I auent tein has found the viscosity-coefficients of solutions of the sodium salts of many organic acids. In the fatty series he found that substitution of CH₄ for H increases the viscosity, while the replacement of H by COOH or OH diminishes it. The change from succinic to malcic acid diminishes the viscosity, but if we remove two more atoms of hydrogen, giving acetylene dicarboxylic acid, we get a large increase.

In the aromatic series the results are less regular. Introduction of a carboxyl group into the ring still diminishes the viscosity, and this diminution is greater in the para-position than in the meta-, and greater in the meta- than in the ortho-; thus the viscosity diminishes regularly in the series shown by the formulæ at the top of p. 271.

According to the usual theory, the electricity which constitutes the current in an electrolyte is carried by charged ions, and it might be expected that the conductivity would be greater the more easily these ions were able to move along under the influence of the electromotive force—that is to say, the less the frictional resistance they had to overcome. On this account Wiedemann thought there would prove to be a connection between the viscosities and conductivities of solutions. Some experiments which he made seemed to point to the conductivity being inversely proportional to the viscosity, but though this was found at a later time to hold only in a few special cases, it has been shown that there is

$$\textbf{C_{e}H_{s}.COONa}, \ \textbf{C_{e}H_{s}} \\ \underbrace{\textbf{COONa}}_{\textbf{COONa}} \\ \textbf{1:2}, \ \textbf{C_{e}H_{s}} \\ \underbrace{\textbf{COONa}}_{\textbf{COONa}} \\ \textbf{1:3}, \ \textbf{C_{e}H_{s}} \\ \underbrace{\textbf{COONa}}_{\textbf{COONa}} \\ \textbf{1:4}.$$

With other replacing groups we have the following series. each being arranged in order of diminishing viscosity : -

$$\begin{array}{l} \textbf{1:2} \ C_{o}H_{4} < \begin{matrix} \text{COONa} \\ \text{NO}_{3} \end{matrix}, \ \textbf{1:3} \ C_{v}H_{4} < \begin{matrix} \text{COONa} \\ \text{NO}_{2} \end{matrix}, \ C_{o}H_{3}\text{COONa}, \ \textbf{1:4} \ C_{s}H_{4} < \begin{matrix} \text{COONa} \\ \text{NO}_{2} \end{matrix}\\ \textbf{1:4} \ C_{v}H_{4} < \begin{matrix} \text{COONa} \\ \text{OH} \end{matrix}, \ C_{v}H_{3}\text{COONa}, \ \textbf{1:3} \ C_{v}H_{4} < \begin{matrix} \text{COONa} \\ \text{OH} \end{matrix}, \ \textbf{1:2} \ C_{v}H_{4} < \begin{matrix} \text{COONa} \\ \text{OH} \end{matrix}\\ \textbf{1:2} \ C_{v}H_{4} < \begin{matrix} \text{COONa} \\ \text{OH} \end{matrix}, \ \textbf{1:4} \ C_{v}H_{4} < \begin{matrix} \text{COONa} \\ \text{OH} \end{matrix}, \ C_{v}H_{3}\text{COONa}, \ \textbf{1:3} \ C_{v}H_{4} < \begin{matrix} \text{COONa} \\ \text{OH} \end{matrix}. \end{array}$$

undoubtedly a close connection between the two

properties.

This connection is shown very clearly by the work of Grotrian (P. 157, 130, 237; 160, 238), who determined the proportional rate of change with temperature of the viscosity and conductivity of salt solutions for various concentrations that is, he calculated from his observations the

values of $\frac{1}{f}\frac{df}{dt}$ and $\frac{1}{h}\frac{dk}{dt}$, where f is the coeffi-

cient of viscosity and k is the electrical conductivity, and found that though not equal they always vary in the same way with the concentration. If curves be drawn with the values of these coefficients at a fixed temperature for ordinates, and the concentrations for abscisse, W. N. Shaw (Camb. Phil. Proc. 7, 21) has shown that the two curves run almost exactly parallel. any peculiarities in the shape of one being repeated in the other.

That the conductivity is not dependent on the viscosity alone is shown by the fact that if we add to an electrolyte such quantities of different non-conductors, as alcohol, sugar, glycerin, &c., as increase the viscosity by the same amount, the conductivity will generally be affected differently by the different substances. Arrhenius (Z. P. C. 9, 495) has investigated this effect at some length. He finds that the conductivity can be expressed by the equation: $l = l_0 \left(1 - \frac{a}{2}x\right)^2$,

where lo is the conductivity of the electrolyte alone, and I that which it has when x p.c. of the water is replaced by a non-conductor. may be taken as defining the change in the conductivity. The change in the viscosity of the electrolyte on the addition of 1 p.c. of non-conductor is the same as the change would be with water alone, and is hence equal to A-1, where A is the constant of the formula $\mu = \mathbf{A}^x$.

On tabulating the values of 1000a and 1000 (A-1) for a number of different salt solutions and non-conductors, it appears that the equation, $1000 \alpha = c + 1000 c'(A-1)$ holds as a first approximation, and the electrolytes fall into four classes, for the members of any one of which the constants c and c' are the same. These classes are:

(1) Solutions of strong acids and bases; (2) Solutions of salts of the type KCl;

K₂SÓ₄; BaCl2. ,,

Arrhenius considers the relation not to be exact, but thinks it should include a term depending on the degree of dissociation, which can be neglected only in the cases of the more completely dissociated salts.

XIV. VOLUME-CHANGES,

BASED ON, v. VOLUMES, SPECIFIC; this vol. PHYSODIN C1011,1007. [125°]. Extracted by ether from the dried lichen Parmelia physodes (or Ceratophylla] and crystallised from alcohol (Gerding, N. Br. Arch. 87, 1). Mass of minute prisms, insol. water. Forms a yellow solution in KOHAq.

PHYSOSTIGMINE v. ESERINE. PHYTO-ALBUMOSES v. PROTEÏDS.

PHYTOLACCIC ACID. Occurs as K salt in the Poke Berry, the fruit of Phytolacca decandra (Terreil, C. R. 91, 856; cf. Claesson, Ph. [3] 10, 566). Extracted by dilute alcohol. Yellowishbrown resin.

PHYTOSTERIN v. vol. ii. p. 149. PHYTO-VITELLIN v. PROTEÏDS.

PIAZTHIOLE $C_6 II_4 < \stackrel{N}{N} > S$. [44°]. (206°).

Formed by heating o-phenylene-diamine with aqueous SO₂ at 190° (Hinsberg, B. 22, 2899). Colourless crystals, sl. sol. hot water. Feeble base. Reduced by tin and HCl to o-phenylenediamine.

Reference.—METHYL-PIAZTHIOLE.
PICENE C₂ H₁₁. [345° cor.]. (520°). V.D.
9:8 (obs.). Occurs in the highest holling portions of brown-coal tar (Burg, B. 13, 1834), and in the residues of Californian petroleum (Graebe a. Walter, B. 14, 175). Appears also to be formed by the action of ethylene bromide and AlCl₃ on naphthalene (Lespeau, Bl. [3] 6, 238). White plates with blue fluorescence, insol. alcohol and ether, sol. boiling solvent naphtha (150°-170°). On oxidation with CrO, it yields picoquinone C₂₂H₁₂O₂, which crystallises from HOAc as a dark orange-red powder, sublimes in red needles, and forms a green solution in pure

H₂SO₁.
Di-bromo-picene C₁₂H₁₂Br₂. [206°]. Necdles.

(from xylene), insol. alcohol.

Picene hydrides C.H., (over 360°) and C.H_{3e} [175°] (over 360°) are got by heating piecne with HIAq and red P at 250° (Liebermann a. Spiegel, B. 22, 781). C₂₂H_{3e} is liquid.

PICHURIN OIL contains the glyceryl ether lauric acid (Sthamer, A. 53, 390).

PICOLINE v. METHYL-PYRIDINE.

PICOLINIC ACID v. Pyridine Carboxylic

Dipicolinic acid v. Pyridine dicarboxylic ACID

DIPICOLYL v. DI-METHYL-DIPYRIDYL. PICRACONITINE v. ACONITE ALKALOIDS. PICRAMIC ACID v. DI-NITRO-AMIDO-PHENOL. PICRAMIDE v. TRI-NITRO-ANILINE.

PICRASMIN C₂₅H₄₆O₁₀. [204°]. A bitter substance which, together with C₂₆H₄₀O₁₀ [209°-

212°], may be extracted by dilute alcohol from Picræna excelsa (Massute, Ar. Ph. [3] 28, 147; C. J. 58, 791). HClAq converts it into picrasmic acid C₃₁H₄₀O₆(CO₂H)₂, while fuming HIAq displaces three methyls.

PICRIC ACID v. TRI-NITRO-PHENOL.

PICRO-ACONITINE v. ACONITE ALKALOIDS. PICROCROCIN C₃, H₃₀O₁₇, [75°]. Obtained by extracting saffron with ether (Kayser, B. 17, 2233). Colourless prisms. V. sol. water and alcohol, sl.sol. ether. Bitter taste. By heating with baryta-water or with dilute acids it is split up into crocose and the ethereal-oil of saffron C₁₀H₁₀,
PICROERYTHRIN v. ERYTHRITE.

PICROLICHENIN $G_{12}\Pi_{20}O_6$. [100°] (A.). **S.G.** 1·176. Extracted by alcohol from the lichen Variolaria amara (Alms, A. 1, 61; Vogel, J. 1857, 515). Trimetric octahedra, sl. sol. hot water, v. sol. alcohol and ether. Tastes very Its alkaline solutions turn red in air.

PICROROCCELLIN C₂,H₃₀N₃O₃. [194°]. Occurs in a variety of the lichen Roccella fuciformis (Stenhouse a. Groves, A. 185, 14). Prisms, insol. water, m. sol. boiling alcohol, sl. sol. ether. Yields benzoic acid when oxidised by chromic acid mixture. Converted by boiling with HOAc and HCl into xanthoroccellin C₂|H₁₈N₂O₂, which crystallises from alcohol in yellow needles [183°]. Boiling dilute (1\), p.c.) NaOHAq converts picroroccellin into C₂|H₂N₂O₃ crystallising from alcohol in prisms [154°].

PICROSCLEROTIN. Occurs in ergot of ryo Dragendorff, C. C. 1878, 125, 141; Blumberg, Ph. [3] 9, 23, 66, 147). Dissolved in acids and is reppd. by ammonia. It is an active poison

with bitter taste. V. ERGOTININE.

PICROTOXIN C₃₀H₃₁O₁₃ (P. a. O.; S.); C₁₃H₁₆O₆ (B. a. K.). Occurs in Cocculus Indicus, the seeds of Menispermum cocculus (Boullay, A. Ch. [1] 30, 209; Casaseca, A. Ch. [2] 30, 307; Oppermann, Mag. Pharm. 35, 233; Pelle-J. Conerbe, A. Ch. [2] 54, 181; Liebig, A.
Logo; Regnault, A. Ch. [2] 68, 160; Barth,
J. pr. [1] 91, 155; Paterno a. Oglialoro, G. 6, 521; 7, 193). It is accompanied by anamirtin picrotin (Barth a. Kretschy, M. 1, 99, 2,796).

Preparation. - 1. The grains are exhausted with boiling alcohol, the extract evaporated, and the residue boiled with water. The aqueous solution is ppd. by lead acctate and the filtrate, freed from lead by H.S, evaporated. The residue is crystallised from benzene and water successively (B. a. K.).-2. The powdered seeds are boiled with water, the filtrate treated with lead acetate and H.S successively, and evaporated to crystallisation. The product is recrystallised from water and alcohol successively (Schmidt, A. 222, 313).

Properties. - Colourless needles, v. sl. sol. cold water, sl. sol. ether and chloroform, v. sol. alcohol. Very poisonous and very bitter. Sol. alkalis. Reduces Fehling's solution and ammoniacal AgNO_a.

Reactions.—1. When boiled with benzeue

for some time it is split up into picrotin and picrotoxinin (Schmidt). Probably the picrotoxin employed was a mixture of these two bodies .- 2. IICl passed into an ethereal solution forms picrotoxide. - 3. Cold AcCl also forms

picrotoxide, but on boiling it vields a crystalline acetyl derivative [185°].—4. NaOAc and Ac₂O form $G_{11}H_{12}G_{2}$ [227°].

Picrotoxinin $G_{13}H_{16}G_{4}$ aq. [201°]. S. 14 at 15°; S. (benzene) 34 at 21°. Obtained from piero-

toxin by treatment with benzene, CHCl, or AcCl. It constitutes about 30 p.c. of crude picrotoxin (Barth a. Kretschy). Colourless needles or plates. Very bitter and very poisonous. V. sol. hot water. Colours H₂SO₄ orangered. Mixed with dry KNO₃ (3 pts.), moistened with H.SO, and saturated with conc. NaOHAq it gives a red colour (Langley, Am. S. [2] 34, 109). After heating with milk of magnesia, the cold filtrate is coloured red by FeCl, the colour being destroyed by HCl. Bromine forms $C_{13}H_{13}BrO_{8}$ [250'-255']. BzCl gives a crystalline compound (not the benzoyl derivative) [238°]

[above 310°]. Picrotoxide (C₁₃H₁₆O₆)x. [above 310°]. Formed by the action of AcCl on picrotoxin, and by passing HCl into its ethereal solution (P. a. O.). Crystalline, insol. ordinary solvents. According to Schmidt, pierotoxide obtained by means of AcCl crystallises in needles [225°], sl.

sol, cold water and alcohol.

Pierotin $C_{25}H_{30}O_{12}$. [c. 247°]. S. 16 at 17°; S. (benzene) 023 at 22° (Schmidt). Constitutes 60 p.c. of crude picrotoxin (B. a. K.). Crystallises with 23 aq, 3 aq, and 4 aq. It is very bitter, but not poisonous. Reduces hot Fehling's solution and ammoniacal AgNO, H2SO forms a yellow solution. BzCl forms a benzoyl

derivative [245°] (S.).

Anamirtin $O_{10}H_{21}O_{10}$. Constitutes 2 p.c. of crude pierotoxin (Barth a. Kretschy, M. I, 131). Short needles (from water), v. sl. sol. benzene. Neither bitter nor poisonous. Turns brown at 260° and black at 280° without melting.

Cocculin C₁₀H₂₆O₁₀. Occurs in small quantity in Cocculus Indicus (Löwenhardt, A. 222, 353). Slender needles, sl. sol. hot water, nearly insol. alcohol and ether. Does not give Langley's reaction. Is perhaps identical with anamirtin.

PICRYL. The radicle tri-nitro-phenyl.
PICRYL CHLORIDE v. CHLORO-TRI-NITRO-

PIGMENTS, ANIMAL.

BILE PIGMENTS. Bile contains bilirubin, bilifuscin, biliprasin, and probably also biliverdin, which is a product of oxidation of bilirubin. Nitric acid changes the colour of the bile pigments through green, blue, and red to yellow (Gmelin). These colours may be observed by adding nitric acid to a dilute solution of the bile pigments in aqueous alkali, or by gently pouring H.SO, into a solution of the pigments mixed with NaNO₃ (Fleischl, Fr. 15, 502). The changes in the absorption spectra produced by nitric acid have been studied by Jaffé (Z. [2] 5, 666). An alcoholic solution of bromine also produces a play of colours with bile pigments (Capranica, G. 11, 430). The absorption spectra of the bile pigments have been studied by Heynsius a. Campbell (Pf. 4, 497) and McMunn (Pr. 35, 388). Bilirubin, hæmoglobin, and chlorophyll all absorb the violet end of the spectrum, giving an abrupt edge: biliverdin transmits more green; biliprasin, bilifusoin, and bilihumin absorb up to between D and E. The colouring matters of bile are probably got by reduction of hæmatine.

itself formed by the action of bile acids on hæmoglobin (McMunn, Pr. 31, 206). According to Latschenberger (M. 9, 52), hæmoglobin yields simultaneously meianin and bile pigments. All the colouring matters of bile, including hæmatine, urobilin (in bile), and bilirubin, are oxidised to choletelin, which body apparently passes into blood serum, and is then excreted by the kidneys. The absorption bands of bile are due to choletelin and urobilin.

Bilirubin C_{r.}H_{s.}N_{*}O₆ (Städeler, A. 132, 323; Maly, A. 181, 106), or C₁₅H₁₈N_{*}O₃ by Raoult's method (Nencki a. Rotschy, M. 10, 568). S. (chloroform) 17 (Thudiohum, Z. [2] 4, 554). Ox gall stones are often largely composed of the lime compound of bilirubin (Maly, A. 175, 76).

Preparation.—Brown human gall stones are powdered and extracted with ether; the residue is boiled with water, and treated with dilute HCl. The mass is washed, dried, and extracted with chloroform; the chloroform is distilled off, and the residue treated with absolute alcohol. It is then treated with ether and alcohol repeatedly, again dissolved in chloroform, and precipitated by absolute alcohol (Burdon-Sandorson).

Properties .- Orange powder, insol. water, nearly insol. ether, v. sl. sol. alcohol, sol. benzene and chloroform. The colour of the skin in jaundice is probably due to bilirubin. Bilirubin dissolves in alkalis, forming an orange solution, which gradually absorbs oxygen from the air, and then gives a green pp. of biliverdin on adding an acid. An alkaline solution of bilirubin mixed with an equal bulk of alcohol gives, on adding HNO, containing nitrous acid, a green colour changing through blue to red. Sodiumamalgam forms hydrobilirubin. Bromine-vapour yields various brominated products (Thudichum, C. J. 28, 389; 30, 27). Br in chloroform gives C. H., Br. N. O., a dark bluish green fowder, forming a dark-blue solution in alcohol or other (Maly, A. 181, 106). Chlorine passed into a solution of bilirubin in CHCl, forms several chlorinated bodies (Thudichum). A solution of p-diazobenzene sulphonic acid added to a solution of bilirubin in chloroform mixed with alcohol gives a red colour changing to blue on adding conc. HClAq, and turned red again on adding an alkali (difference from other bile-pigments) (Ehrlich, Fr. 23, 275).—CaC32H31N4O6. Occurs in gall stones. Obtained also by ppg. an ammoniacal solution by CaCl2, as brown flakes drying to a lustrous dark-green mass, which yields a dark-blue powder.

Hydrobilirubin C32II,0N,O7. Obtained by reducing bilirubin in alkaline solution with sodium-amalgam (Maly, A. 163, 77). According to McMunn it is not, as had been stated, identical with the urobilin which is found in normal urine, in the urine of febrile patients (Jaffé, Virchow's Archiv, 47; Disqué, II. 2, 271), and in excrement (Vaulair a. Masius, Centralbl. f. d. Med. Wissensch. 1871, No. 24). A similar substance is formed by reducing hamoglobin, hamatine, or hamatoporphyrin in alcoholic solution with tin and HCl (Hoppe-Seyler, B. 7, 1065; Le Nobel, C. C. 1887, 538; McMunn, Proc. Physiol. Soc. 1888, 1), and by the action of H.SO, on a solution of albumen in HOAc (Michailoff, J. R. 16, 269). Reddish-brown powder with green lustre, sl. sol. water, v. sol. alcohol, m. sol. ether. Its alkaline

VOL. IV.

solutions are brown, its solution in chloroform is yellowish-red. The alcoholic solution shows an absorption-band near F. Does not give Gmelin's reaction with HNO₂. May be reduced by sodium-amalgam or by tin and HOI to a colourless product, which in acid solutions is reoxidised by air to hydrobilirubin.

Choleteliu $O_{i_1}H_{i_1}N_{i_2}O_{g}$. Occurs in normal urine, and is obtained by passing nitrous vapours into a solution of bilirubin in alcohol (Heynsius a. Campbell; McMunn, J. Th. 1881, 213). Brown amorphous 'powder, sol. alkalis and alkaline carbonates, alcohol, ether, and chloroform. Ammoniacal AgNO₃ ppts. reddish-brown $C_{15}H_{18}Ag_{i_2}N_{i_3}O_{g}$. Does not give Gmelin's reaction. Its absorption spectrum contains a broad band

from b to F.

Biliverdin C₂,H₃,N₄O₈. Formed by oxidation of a solution of bilirubin by air or by PbO₂. Dark-green powder, iusol. water and chlorotorm, sl. sol. ether, v. sol. alcohol, CS₂, and benzeno. Its solutions are green. Its alcoholic solution gives dark-green pps. with buyta-water, ammoniacal CaCl₂, and AgNO₃. Ag₂O added to its alcoholic solution ppts. bilipurpin, sol. NH₂Aq and reppd. by HCl as a purple powder. Prolonged treatment with Ag₂O converts bilipurpin into yellow biliflavin. HNO₃ added to an alcoholic solution of biliverdin gives a bluish-violet, red and, finally, yellow colour (Thudiclum).

red, and, finally, yellow colour (Thudichum).

Bilifuscin C₁, H₁₀N₁O₂. Prepared by washing gall stones with ether, hot water, and chloroform, adding dilute HClAq, and extracting with hot chbroform. The extract is evaporated and the bilifuscin dissolved in alcohol, which leaves bilirubin undissolved (Brücka, J. pr. 77, 72; Städeler, A. 132, 325). Almost black mass, which yields a dark-brown powder. Forms a brown solution in alcohol and alkalis, nearly insol. water, ether, and chloroform. Gives Gmelin's colour-reaction. Ppd. by ammoniacal CaCl₂. Simony (Sitz. W. [3] 73, 181) obtained from the bile of a corpse a bilifuscin which did not give Gmelin's reaction, and which formed an olive-brown solution in alcohol, HOAc, and alkalis.

Biliprasin C₁₀II.₂N₂O₂. Extracted by alcohol from the residue of gall stones from which bilirubin and bilifuscin have been removed by chloroform (Städeler). Nearly black mass, yielding a greenish-black powder, insol. water, ether, and chloroform, v. e. sol. alcohol, forming a green solution which, unlike one of biliverdin, is turned brown by ammonia. Gives Gmelin's reactic a.

Bilihumin. Left after extracting biliprasin with alcohol (S.). Black powder, m. sol. warm NaOHAq. Exhibits Gmelin's reaction.

Bilicyanin. A product of partial oxidation of bilirubin and other bile pigments (Maly, Sits. IV. [2] 59, 597). Prepared by adding an alcoholic solution of Bit to a colution of bilirubin in chloroform. Occurs in gall stones. Its alcoholic solution is blue, but turned dingy green by alkalis, the blue colour being restored by acids. Bile also contains a blue substance strongly resembling indigo, forming a yellowish solution in alkalis (Ritter, Bl. [2] 13, 212; Andouard, Bl. [2] 31, 139).

URINARY PIOMENTS. Urine usually contains urobilin (v. supra). After urine, containing urobilin, has been mixed with its own bulk of

HClAq and heated to boiling, and then allowed to cool, the urobilin may be extracted by ether and recognised by its absorption band (Grimbert, J. Ph. [5] 18, 481). According to McMunn (Proc. Physiol. Soc. 1888, 5), there are two kinds of urobilin, one in normal urine and the other in pathological urine, and neither is identical with hydrobilirubin. Normal urobilin is identical with a pigment got from acid hæmatin by successive treatment with H2O2 and sodium-amalgam. By the action of oxidising agents indigo-blue and indirubin can be obtained from urine (v. Indigo). Pigments can also be obtained by boiling urine with HClAq.

Uromelanin. Prepared by evaporating urine to one-sixth of its bulk at 60°, adding 10 p.c. HCl, and, after two days, removing uric acid by filtration. The filtrate is then boiled for 18 hours, and the ppd. pigment washed with water, alcohol, and ether, dissolved in NaOKAq, and reppd. by H₂SO₄ (Udranski, *II.* 11, 537; 12, 33; cf. Plosz, *H.* 8, 89). Brownish-black plates, insol. cold water, ether, and chloroform, sl. sol. alcohol and HClAq, v. sol. isoamyl alcohol and alkalis. Not decomposed at 115°. Potash-fusion yields NH, formic, acetic, butyric, and protocatechuic acids and pyrocatechin. Urine contains '03 p.c. of this substance, which appears to be a humous body formed by decomposition of the reducing substance of normal urine.

Urofuscohematin C₃₁H₃₁N₁O₁₃ (?) and urorubrohematin C₃₁H₃₂N₄FeO₁₃ (?) were obtained by Baumstark (B.7, 1170) from the urine of a patient suffering from Lepra. Urofuscohæmatin is a black pitchy substance, insol. water, alcohol, ether, chloroform, acids, and NaClAq, sol. alkalis, alkaline carbonates, and alkaline phosphates, forming brown solutions. Urorubrohæmatin is a light blue-black mass, which differs from urofuscohematin in not being ppd. when HCl is added to its solution in NaOHAq.

Black pigment in Mclanuria, v. vol. iii. p. 199.

Urorosein. An unstable substance which can sometimes be extracted from acidified pathological urine by isoamyl alcohol, to which it imparts a rose colour. The solution shows an absorption band in the green (Nencki a. Sieber, J. pr. [2] 26, 333). A similar substance (urorubin) was extracted by ether from urine that had been boiled 15 minutes with 7 p.c. HCl, exposed to air (Plosz, H. 8, 85). It was left on evaporation as a dark cherry-red mass. Apparently the same pigment, or rather its leuco-compound, occurs in urine of dogs after administration of skatole (Mester, H. 12, 130). The pigment itself is then got by adding HCl to an alcoholic, ethereal, or aqueous extract of the evaporated urine.

OTHER PIGMENTS. Blood pigments v. H.EMOGLOBIN. Muscle pigments v. Muscle.

Eye pigment v. Melanin. A purple pigment occurs in the retina of animals. It is insol. ordinary solvents, but dissolves in bile, and in an aqueous solution of the bile acids. its colour in daylight, but recovers it in the dark (Boll, J. Th. 1877, 318; Kühne, J. Th. 1877, 318; 1878, 279; Ayres, J. Th. 1879, 259).

Yellow pigment of animals v. Lutrig.

Tetronerythrin. A red pigment extracted by chloroform from the red spot in the eye of the blackcock and red grouse (Wurm, J. 1872, 842; 1875, 885; Merejkowski, J. Th. 1881, 871). H.SO, gives a blue colour changing to black.

Pyocyanin. Occurs in blue pus (Fordos, J. 1860, 596; Lücke, J. 1863, 658; Gessard, J. Th. 1882, 55). It is formed, together with other pigments, by Bacillus pyocyanicus in peptonised geiatin (Babès, C. R. Soc. Biol. [9] 1, 438). Blue trimetric prisms or needles (from CHCl,) which become green on keeping, v. sol. chloroform, alcohol, and water. Turned red by acids, but becomes blue again on adding alkalis. It shows two absorption bands, one being in the ultraviolet:

Pigments of Purpura lapillus. The pigments are furnished by a yellowish-white fascia which extends along the rectum (Letellier, C. R. 109, 82). This contains two green substances, applegreen monoclinic crystals turned dark blue by light, and dull-green trimetric crystals turned violet or crimson by light. The green substances are sol. ether and chloroform, but become in-soluble on exposure to light. The change to purple (punicin) is accompanied by absorption of oxygen (Schunck, B. 12, 1359).

Pigments of sea anemones. Actinia mesembryanthemum contains a pigment allied to hemo-chromogen and hemato-porphyrin, and to harmatine. It also contains biliverdin. Actinia cercus, Bunodes ballii, and Sagartia bellis contain a green pigment resembling chloro-fucin, but not identical with any animal or plant chloro-

phyll (McMunn, Pr. 38, 85).
PIGMENTS, VEGETABLE, v. CHLOROPHYLL, ALKANET, BETH-A-BARRA COLOUR, BIXIN, BRAZILEÏN, CHICA, COLEÏN, CURCUMIN, DRAGON'S BLOOD, ILE-MATOXYLIN, LITHOSPERMUM ERYTHRORHIZON, LIT-MUS, LUTEIC ACID, PALMELLIN, and SANTALIN.

Anthocyanin. The blue pigment of flowers is sol. water and alcohol, insol. ether. It is free from N, and is turned red by acids and green by alkalis (Fremy a. Cloez, J. Ph. [3] 25, 249; Filhol, C. R. 39, 194; 50, 345, 1132; Schönn, Fr. 9, 328).

Anthoxanthin. Yellow flowers contain anthoxanthin, which is insol. water, and anthoxanthein, which is sol. water. Both are sol. alcohol and ether. The petals of Rosa gallica contain a pigment sol. alcohol, insol. ether, which forms amorphous Pb2C21H30O30 (?) (H. Senier, Ph. [3] 7, The colouring matter of the berries of Phytolacca decandra has been examined by Hilger

and Bischoff, L. V. 23, 456; B. C. 1879, 875).
PILIGANINE. A very poisonous alkaloid occurring in piligan, a Brazilian lycopod (Adrian, C. R. 102, 1322). Soft mass, with alkaline reaction, fuming with HCl. Sol. water, alcohol, and chloroform, sl. sol. ether. Emeto-cathartic in action. Its hydrochloride forms minute deliquescent crystals.

PILOCARPENE $C_{10}H_{18}$. (178°). S.G. 18 852. V.D. 4°0. $[a]_{D}=1$ 21. Obtained by steam distillation from jaborandi leaves (Hardy, BL, [2]) 24, 498). Fragrant oil. Dextrorotatory. Yields

CH_CH_2HCI [49:5°].

PILOCABPINE C₁₁H₁₂N₂O₂ i.s.

CH_CH_CH_CC.CMe
CO.CMe
CO.CMe [1599] (Blyth). [a]n = 101.6 in a 7.24 p.c. solution.

Occurs in the leaves and bark of jaborandi (Pilocarpus) (Gerrard, Ph. [3] 5, 865, 965; Hardy, Bl. [2] 24, 497; Kingzett, C. J. 30, 367; Harnack a. Meyer, A. 204, 67). Prepared synthetically from a-oxy-a-pyridyl-propionic acid CH₃.C(OH)(C₅H₄N).CO₂H by treatment with phosphorus tribromide and heating the resulting CH₂.CBr(C₃H₄N)CO₂H with NMe₂ at 150°. In this way pilocarpidine C10H11N2O2 is formed, and this is converted into pilocarpine by heating with MeI and MeOH, and oxidising the product with aqueous KMnO, (Hardy a. Calmels, C. R. 105, 68; Bl. [2] 48, 233).

Preparation.-Jaborandi leaves are digested with 1 p.c. HClAq, the extract treated with Pb(OAc)₂, filtered, and the filtrate ppd. by phosphomolybdic acid. The pp. is decomposed by baryta-water at 100° (Pöhl, Bl. [2] 34, 340).

Properties .- Crystalline; begins to sublime at 153°; at 160°-170° the sublimate consists of yellow drops (Blyth). Dextrorotatory. Pilocarpine may be estimated by means of the aurochloride (Christensen, Ph. [3] 12, 400). Poisonous, being diaphoretic. Forms resinous compounds with potash, NaOH, and baryta; these compounds are v. sol. water, v. sl. sol. alcohol, and are decomposed by acids, even by CO2. They may be considered to be salts of

pilocarpic acid C11H18N2O3.

Reactions .- 1. Fuming HNO, (300 pts.) converts it into pilocarpidine nitrate (Chastaing, C. R. 94, 968). -2. Boiling with water for twelve hours splits it up into trimethylamine and oxypyridyl-propionic acid (Hardy a. Calmels, C. R. 102, 1562).-3. Boiling HClAq forms McOH and pilocarpidine.—4. KMnO₄ forms NMe₃ oxypyridyl-malonic acid, and finally pyridine (β)-carboxylic acid.—5. Bromine added to a chloroform solution forms C11H15N2O2Bra, crystallising in minute prisms, converted by moist Ag.O into di-bromo-pilocarpine C₁₁H₁₁Br₂N₂O₂ (Chastaing, C. R. 97, 1435). Chlorine forms C₁₁H₁₂N₂O₂Cl₃, which is amorphous, and slowly forms crystalline $C_{11}H_{15}N_2O_2Cl_3$.—6. Yields NMc_3 when distilled with potash (Harnack a. Meyer; cf. Chastaing, C. R. 94, 223).—7. The barium compound on distillation yields jabonine C₉H₁₁N₂, an oil with fætid odour, yielding the amorphous salts

B'AuCl, B'HAuCl, B'.PtCl, and B'2H.PtCl, Salts.—B'HCl: needles, v. sol. alcohol. B'HNO: trimetric lamelle. -B',H,PtCla: golden tablets (from hot water).—B'PtCl;: crystals.—B'HAuCl4: minute needles.—B'AuCl3 [88°]: slender needles.—B'2AuCl₂: small needles.—B'HAu₂Cl₂: minute needles.—B'AgNO₂: minute B'CrN,H₁(SCN)₁: red silky needles, sol. alcohol (Christensen, J. pr. [2] 45, 368).—B'₂CuO₂II₁; green powder, ppd. by adding CuCl₂ to a solution of nilegenies in the statement. of pilocarpine in baryta-water.—B'AgOH: curdy pp.—B'Me,PtCl,: crystals.—B'EtI. [c. 30°].—
B'EtBr. [c. 60°]. Very hygroscopic (Chastaing,

C. R. 101, 507).

Pilocarpidine C₁₀H₁, N₂O₂ i.e. NMe₂.CMe(C₃H₁,N).CO₂H. Occurs in jaborandi leaves (Harnack, A. 238, 230). Formed by the action of HClAq or fuming HNO, on pilocarpine, by heating dry pilocarpine for twenty-four hours at 120°, by boiling pilocarpine or its baryta com-pound with water for forty eight hours, and by heating the baryta compound for thirty minutes

at 150°. Prepared synthetically by heating CH_,CBr(C,H,N).CO,H with trimethylamine at 150° (H. a. C.). Very deliquescent, m. sol. water, v. sol. alcohol. Acts physiologically like pilocarpine, but not so strongly. Its alkaline salts are gummy, sol. water, insol. alcohol, and deare gmmy, sot. water, msot. accord, and decomposed by CO₂.—B'HCl: radiating needles, v. soluble in water.—B'HAuCl, aq. Rectangular prisms. — B'AuCl₃. [145°]. Yellow plates. —B'H.PtCl, aq: small red prisms.—B'MeI.— B'McAuCl, [153°]. Prismatic needles. Changes when fused into McCl and B'AuCl,

PIMARIC ACID $C_{y_0}H_{y_0}O_{y_0}$ [211°]. [a]_p = 72.5 in a 3.8 p.c. (saturated) alcoholic solution at 15°. Occurs in galipot, the hardened resin of Pinus maritima (Laurent, A. Ch. [2] 72, 384; [3] 22, 459; Sievert, Z. f. d. g. Naturwiss. 14, 311; Maly, A. 129, 94; 132, 253; Strecker a. Duvernoy, A. 148, 143; 150, 131; Cailliot, Bl. [2] 21, 387; Bruylante, B. 11, 447; Haller, B. 18, 2165; Vesterberg, B. 18, 3331; 19, 2167; 20, 3248).

Preparation.—Finely-divided galipot is stirred with half its weight of dilute (70 p.c.) alcohol, left for some days, and squeezed in a cloth. The press-cake is treated several times in this way, finally with 80 p.c. alcohol. The residue is dissolved in somewhat more than the calculated quantity of hot dilute (3 p.c.) NaOHAq. The mixture of Na salts that separates after some days is recrystallised from water, decomposed by HCl, and the free acids crystallised from alcohol or HOAc. (\$)-Pimaric acid remains in the mother-liquor.

Properties .- Rectangular plates, insol. water, v. sl. sol. alcohol, ether, and HOAc, m. sol. hot ligroin, m. sol. hot NaOIIAq, sl. sol. NH,Aq. On shaking the ethereal solution with a drop of ammonia the NH, salt separates in slender needles. Not reduced by sodium-amalgam. May be distilled in vacuo. Dextrorotatory. HIAq (S.G. 1.96) forms C20H3, (320°-330° uncor.). By distillation of the (crude) Ca salt Bruylants obtained ethylene, propylene, amylene, acetone, methyl ethyl ketone, di-ethyl ketone, toluene, xylene, ethyl-toluene, terebene, and diterebene.

Salts.-All the salts are insol. ether. KA' (dried at 100°). Soapy mass of pliant needles .-NaA' 5aq. Slender needles (from 80 p.c. alcohol), sl. sol. cold water. - CaA', aq: needles. -BaA', 9aq: pliant needles. — CuA', — PbA', — AgA': amorphous pp., becoming crystalline.

Ethers.—Med. [69°].—Eth. [52°].

Chloride C₂₀H₂₀OCl. [66°]. Got by adding
PCl, to a solution of the acid in CS. Small prisms, v. e. sol. ether and CS2.

prising, v. e. soi. tenior and C_{3x} . (3). Finario acid $C_{3x}H_{3x}O_{2x}$. [140°-150°]. S. 9·26 in 98 p.c. alcohol at 15°. [a]_{3x} = -272° in a 3·17 p.c. alcoholic solution. Obtained as above (Vesterberg, B. 20, 3248). Trimetric prisms; a:b:c=*810:1: '614, insc'. water, v. sol. NH₃Aq. Lævorotatory.—NaA': m. sol. ether.—PbA'; needles, insol. alcohol and ether. Haller (B. 18,

2165) obtained an inactive pimaric acid [c. 149°], which was perhaps a mixture of the dextro- and lævo- varieties.

PIMELIC ACID C,H₁₇O₄ i.e.
CO,H.CHPr.CH_.CO₂H. Isopropyl-succinic acid.
Mol. w. 160. [114°]. Electrical conductivity:
Walden, B. 24, 2037. Formed by fusing camphoric acid with potash (Hlasiwitz a. Grabowski,

A. 145, 205; Kachler, A. 169, 168). Formed ! also by heating either of the following isopentane tricarboxylic acids: (CO₂H)₂CP₇.CH₂CO₂Hor CO₂H₃.CH₂P₇.CH₃CO₄Hor CO₂H₃.CH₄P₇.CH(CO₂H)₂. (Waltz, B. 15, 609; A. 214, 60; Hjelt, B. 16, 2622; Schleicher, A. 267, 123). Obtained also by the action of KOHAq on isopropyl-acetyl-succinic ether (Roser, A. 220, 276). According to Arppe (J. 1864, 377) it is not formed, as stated by Laurent (A. Ch. [2] 66, 168), by oxidation of oleïc acid. Nodules (from water) or triclinic crystals; a:b:c=497:1: 599; $a=81^{\circ}$ 50'; $\beta=100^{\circ}$ 2'; $\gamma=85^{\circ}$ 6' (Wreden, A. 163, 323; Von Zepharovitch, Sitz. W. [1] 73, 7). V. sol. water, alcohol, and ether. Yields butyric

said when fused with potash.

Salts.—(NH₄)_AA". Hygroscopic leaflets.—
Na_AA" (dried at 130°).—CaA" aq: sandy crystal-Na_A" (dried at 130°).—CaA"aq: sandy crystal-line powder. S. 47 at 9°; '25 at 100° (Bauer a. Schuler, J. 1878, 734; B. 10, 2031; M. 4, 345); '30 at 13° (Roser).—SrA": necrly insol. hot water, v. e. sol. cold water.—Ag_AA": pp. Ethyl ether EtA". (236°240°). Chloride C,H₁₀O₂Cl₂. (210°). Anhydride C,H₁₀O₂Cl₂. (216°). Got by distilling the acid. Becaused into the acid.

distilling the acid. Reconverted into the acid by alkalis.

Imide C.H₁₁NO₂. [60°]. Got by heating the ammonium salt. Tables (from water) or small needles (from alcohol-ligroin). Insol. ligroin, v. sol. alcohol and ether.

n-Pimelic acid CH2(CH2.CH2.CO2H)2. [103°]. (272° at 100 mm.) (Krafft a. Noerdlinger, B. 22, 818). S. 4·2 at 20°. H.C.p. 828,900. H.F. 243,100 (Stohmann, J. pr. [2] 45, 480).

Formation.—1. By heating suberone with HNO₂ (Dale a. Schorlemmer, C. J. 35, 686; A. 199, 147) .- 2. By heating furonic acid with HIAq and P at 200° (Baeyer, B. 10, 1858).-8. By heating pentane ω-tetra-carboxylic acid (Perkin, jun., C. J. 51, 242; 59, 825; B. 18, 3249).—4. By oxidation of myristic acid with HNO, (Noerdlinger, B. 19, 1898).—5. By reducing CO(CH, CH, CH, H), (cf. FURFURYL-ACRYLIC ACID) (Marckwald, B. 21, 1398).

Properties. - Rectangular trimetric plates (from water), v. sol. alcohol, ether, and hot benzene. May be sublimed. NaOEt forms C₁,H₂₀Na₂O₃, a white powder, insol. ether, sol. water. Not converted into anhydride by AcCl

or by POl, (Volhard, A. 267, 82). Salts.—BaA"aq.—CaA". Deposited as

granular powder when a cold saturated solution is heated.— Ag,A": white pp.

Ethyl ether Et,A". S.G. ‡ 1:0080; †5
9988; ‡ 9920. M.M. 11:424. Oll with penetrating odour (Perkin, C. J. 59, 826).

Pimelic acid C,H₁₁O₄, [103° cor.]. Got by heating chelidonic acid with HIAq at 205° (Haitinger a. Lieben, M. 5, 358). Monoclinic tables, v. sol. hot benzene. Perhaps identical with n-pimelic acid.

(8)-Pimelic acid C, H10(CO2H)2. [106°]. Occurs among the products of oxidation of castor oil and earth-nut oil with nitric acid (Gantter a. Hell, B. 17, 2212). Large tables (from water). Readily forms supersaturated solutions.

BaA"aq: plates.—PbA".—CuA".—Ag,A": pp.

Iso pimelie acid 'O,H., (CO,H). [104°].

Formed from amylene bromide by successive treatment with alcoholic KCy and HClAq at 170° (Bauer, M. 4, 345; Hell, B. 24, 1389). Prisms,

v. sol. water and alcohol. Begins to form an v. sol. water and atcomot. Degins to form an anhydride at 185.— (NH₄)₂A".— BaA" 1₂aq; sandy powder.—CaA". S. 2 at 22°; 14 at 100°.— SrA" 4aq.—NiA" 2½aq.—ZnA".—PbA". S. 01 at 10°.—CuA"aq. S. 04 at 16°; 07 at 100°. Bluish-green plates.—CdA"2aq: needles. S. 12 at 15°; 13 at 100°.—Ag₂A".

一点点 医二甲基甲基甲基

An amorphous pimelic acid was got by Bauer, as well as the preceding acid, from amylene bromide. Its Ca salt was more soluble (S. 4·7).

Pimelic acid C,H₁₂O₄. [87°]. Got by oxidising menthol with KMnO₄ in acid solution (Arth, A. Ch. [6] 7, 455; C. R. 107, 107). Needles, v. sol. water. Can be extracted by ether from its aqueous solution.—Ag2'\".

Isomerides — v. DI-METHYL-GLUTARIC ACID,

METHYL-ETHYL-SUCCINIC ACID, TRI-METHYL-SUC-CINIC ACID, and PROPYL-SUCCINIC ACID.

PIMENTO. The volatile oil obtained from the pods and seeds of Myrtus Pimenta contains eugenol and a terpene (255°) S.G. 18 98 (Bonastre, J. Ph. 11, 187; Oeser, A. 131, 277).

PINACOLIC ALCOHOL v. Sec - HEXYL PINACOLIN v. METHYL tert - BUTYL RETONE.

PINACULIN v. METHYL Lett-BUTYL RETONE.
Benzpinacolin v. vol. i. p. 488.
PINACONE C₄H₁, O. i.e. CMe₂(OH). CMe₂(OH).
Hexylene glycol. [38°]. (170° cor.). S.G. 45
9672; 35 9609. M.M. 7-245 (Perkin, C. J. 45,
506). H.C. 897,697 (Louguinine, A. Ch. [5] 25,
143). Formed by the action of Na or sodum. amalgam on aqueous acetone (Fittig, A. 110, 25; 114, 54; Städeler, A. 111, 277; Friedel, A. 124, 324; Bl. [2] 19, 289; Linnemann, A. Suppl. 8, 374). Formed also from CMe, Br.CMe, Br by successive treatment with AgOAc and baryta (Pawloff, A. 196, 122). Small needles (from CS₂), v, sol. cold alcohol and ether, sl. sol. cold CS₂. Sl. sol. cold water, but v. sol. hot water, separating on cooling as a hydrate $C_0H_{14}O_2$ 6aq [46.5°], crystallising in four-sided tables, decomposed by distillation into water and

Reactions .- 1. Chromic acid mixture reconverts it into acetone. -2. Gaseous HI yields PrI and some hexane (Linnemann, Sitz. W. [2] 63, 255). HIAq at 100° forms C₆H₁₁I (Bouchardat, Z. 1871, 699).—8. Boiling dilute H₂SO₄ converts it into pinacolin. Heating with HOAc has the same effect.—4. POCl, forms di-chloro-hexane [160°] (Friedel a. Silva, B. 6, 35).—5. Does not form an acctal when heated with aldehyde (Lochert, A. Ch. [6] 16, 60).-6. When passed through a A. Oh. [6] 10, 00).—0. When passed whough a red-hot tube it yields acctone and isopropyl alcohol (Thorner a. Zincke, B. 18, 645).

PINACONES. Compounds of the form HO.CRR'.CRR'.OH, where R and R are alkyls.

They are obtained by reduction of ketones. On treatment with dehydrating agents they yield (β)-pinacolins CRR', CO.R or isomeric (α)-pinacolins OCRR' or CRR'.O.CRR'. If in these formulæ R = H, the (β)-pinacolin will be an aldehyde; while if at the same time R'= H, we find that glycol is the simplest pinacone, aldehyde the simplest (8)-pinacolin, and ethylene oxide the simplest (a)-pinacolin (Zincke, A. 216, 296). Some (\$)-pinacolins are decomposed by heating with soda-lime or alcoholic potash, thus: PhOX, COPh + HO = PhOX, H + HOBs | Zincke

a. Thorner, B. 11, 65; Zagumenny, J. R. 12. 429); but phenyl (a) naphthyl (B) pinacolin reacts with alcoholic potash, thus: PhC(C, H, J, OOPh+ H, O=PhC(C, H, J, OH+Ph.CO.H (Elbs, J. pr. [2] 35, 506).

PINE-APPLE OIL. Artificial pine-apple oil may be made by dissolving butyric ether in alcohol (Hofmann, A. 81, 87). PINENE v. TERPENES.

PINEY TALLOW. A fat obtained by boiling the fruits of Valeria indica (of Malabar). Melts at 30° to 38°. Its fatty acids consist of palmitic acid (75 p.c.) and oleic acid (25 p.c.) (Dal-Sie, G. 8, 107)

PINIPICRIN C₂H_{3e}O₁₁. Occurs in the needles and bark of the Scotch fir (*Pinus sylvestris*) and in the green parts of *Thuja occidentale* (Kawalier, *Sitz. W.* 11, 350; 13, 515). Bright-yellow amorphous powder, beginning to soften at 55°, and quite liquid at 100°. Hygroscopic. Tastes bitter. V. sol. water, sol. alcohol, insol. ether. Boiling dilute H,SO, yields glucose (2 mols.) and ericinol C10H16O (1 mol.), v. vol. ii. p. 458.

PINITANNIC ACID C₁₄H₁₆O₈? Occurs in

the needles of the Scotch fir and in the green parts of the Arbor vitee (Thuja occidentale) (Kawalier, Sitz. W. 11, 357; 29, 19). Reddish-yellow powder, v. sol. water, alcohol, and ether. FeCl, colours its aqueous solution brown. Gives yellow pps. with lead acetate and subacetate.

Not ppd. by gelatin.

PINITE C,H,10. Methyl ether of dextrorotatory inosite. [186°]. [a], = 65° 51'. Supposed to be extracted by water from the hardened sap of Pinus lambertiana of California (Berthelot, A. Ch. [3] 46, 76; Johnson, Am. S. [2] 22, 6; Combes, C. R. 110, 46; Maquenne, A. Ch. [6] 22, 264). Crystalline crusts, v. e. sol. water, almost insol. alcohol. Tastes sweet. Dextrorotatory. Non-fermentable. Does not reduce Fehling's solution. HIAq splits it up into MeI and dextrorotatory inosite [248°]. Pinite is identical with materite and sennite.

PINOL $C_{10}H_{10}O$ *i.e.* $C_{0}H_{0}OMeFr$. (184°). S.G. 2º .953; $\mu_{D} = 1.469$. Formed, together with pinene nitroso-chloride when oil of turpentine is treated with HOAc, nitrous ether, and HCIAq (Wallach, A. 253, 251; 259, 322; 268, 222; B. 24, 1552). Purified by conversion into the di-bromide C₁₀H₁₆Br₂O [94°], which is dissolved in dry benzene and treated with sodium-wire.

Liquid, smelling like cineol.

Reactions.-1. Oxidised by KMnO, to CO, oxalic acid, and terebic acid [176°].-2. Br forms C₁,H₁,Br₂O and C₁,H₁,Br₂O [160°]. — 3. HBr forms an addition product converted by water into the hydrate C₁,N₁OH₂O [131°] which is not attacked by Ac₂O, but is reconverted into pinol by warming with dilute H.SO., and yields terpenylic acid [57°] on oxidation by KMnO.

Dibromide C₁₆H₁₆Br₂O. [94°]. (144° at

11 mm.). Trimetric crystals; a:b:c = 570:1:1.555. Insol. water, volatile with steam. Converted by alcoholic potash into 'pinol glycollic ether' C₁eH_{1e}(OEt)₂O [53°] (c. 115° at 14 mm.). AgOAc forms O_{1e}H_{1e}(OAc)₂O [98°] (127° at 13 mm.), which on saponification by hot dilute H₂SO, yields 'pinol-glycol' O_{1e}H_{1e}(OH)₂O [125°], crystallizing in matted needles, v. e. sol. chloroform. Boiling with water and Pb(OH), also converts the dibromide into the glycol. Silver propionate yields C10H16(O.COEt), [106°]. Formic acid at 100° reduces the dibromide to cymene.

Nitroso-chloride C, H, ONOCI. [108° Formed by the action of amyl nitrite and HCl on pinol in HOAc (Wallach, A. 253, 261). Converted by alcoholic NH, into the nitrolamine C_{1e}H₁₆ONONH₂ (130° at 14 mm.), a viscid mass which yields a crystalline hydrochloride, B'HCl. Aniline, piperidine, and benzylamine form the three analogous bodies $C_{10}H_{10}O.NO.NHPh$ [175°], $C_{10}H_{10}O.NO.NC_{1}H_{10}$ [154°], and the compound $C_{10}H_{10}O.NO.NC_{1}H_{10}$ [136°], each of which forms a crystalline hydrochloride. (β)-Naphthylamine forms, in like manner, pinol-nitrol-naphthylamine C₁₀H₁₆O.NO.NHC₁₀H, [195°].

PINYLAMINE C₁₀H₁₃NH₂. (208°). S.G. M. 943. Formed by reducing with zinc-dust and HOAc nitroso-pinene C10 H13NO [1320], which is got from C, H NOCl and alcoholic NaOH (Wallach a. Lorenz, A. 268, 197; B. 24, 1550). Oil, turning yellow in air, and giving off NH: Absorbs CO, from air, forming a solid carbonate Benzoic aldehyde forms C₁₀H₁₃N:CHPh [58°] furfuraldehyde gives C₁₀H₁₃N:CH.C₄H₃O [81°] whilst salicylic aldehyde forms the compound C₁₀H₁,N:CH.C₂H₄.OH [109°].—B'HCl. [230°]. Needles (from water). Yields cymene on distilla-tion.—B'₂H₂PtCl₃. Yellow plates or needles.— B'HNO,. Crystals, sl. sol. cold water. - B', H, SO. -B'HCyS. [136°]. Prisms (from water).-B'₂H₂C₂O₄. [248°]. Scales.

Acetyl derivative C₁₀H₁₅NHAc. [109°] Benzoyl derivative. [125°]. Needles.

PINYL-UREA NH CO.NHC HIS. [160° Formed from pinylamine hydrochloride and potassium cyanate (Wallach, A. 268, 204). Needles, v. sol. alcohol.

PIPECOLINE v. METHYL-PYRIDINE HEXA-HYDRIDE.

PIPERAZINE v. Pyrazine HEXAHYDRIDE. PIPERHYDRONIC ACID v. Methylene derivative of DI-OXY-PHENYL-VALERIC ACID.

PIPERIC ACID C12H10O4 i.s.

CH₂<0>C₆H₂.CH:CH:CH:CH:CO₂H. Mol. w. [217°]. S. (alcohol) :37 in the cold; 2 at 78°. Formed, together with piperidine, by boiling piperine with alcoholic potash (Von Babo; Strecker, A. 105, 317; 118, 280; G. C. Foster, C. J. 15, 17; Fittig a. Mielk, A. 152, 25; 172, 134). Yellowish needles (from alcohol). After fusion it melts at 213°. Nearly insol. water, m. sol. hot alcohol and ether.

Reactions .- 1. Reduced by sodium-amalgam to two hydropiperic acids, which are the methylene derivatives of di-oxy-phenyl-angelic acids CH.O.:C.H., CH., CH.; CH., CO.H. [78°] and CH.O.:C., H., CH., CH.; CH., CH.; CH., CO.H. [131°] (Regel, B. 20, 414).—2. Dilute alkaline potassium permanganate at 4° oxidises piperic acid to piperonal CH.O.: C.H. CHO and racemic acid (Doebner, B. 23, 2375).-3. Potash-fusion yields protocatechuic, oxalic, and acetic acids .- 4. Bromine in CC2 forms a tetrabromide which decomposes at 160°-165°.

Salts. – NH,A'. Satiny scales. — KA'. — BaA'. S. '02 in the cold.—AgA': powder. Ethyl ether EtA'. [78°]. Plates. · Reference .- BRONO-PIPERIC ACID.

PIPERIDEINE. A name for Pyridine tetra-

slowly adding v-chloro-piperidine to a boiling 10 p.c. solution of potash in alcohol (Lellmann a. Schwaderer, B. 22, 1000, 1318). Monoclinic crystals, sl. sol. water, v. sol. alcohol and ether. Between 200° and 230° it begins to dissociate into (2 mols. of) pyridine tetrahydride; hence it has no constant boiling-point. Slightly volatile with steam. Ac,O forms an acetyl derivative (220°). S.G. 105 1.0531. Tin and conc. HClAq reduce it to piperidine. Phenyl thiocarbinide gives $C_{10}H_{11}N_2$ CS.NHPh [144°]. CS₂ forms $C_{10}H_{18}N_2$ CS₂, crystallising in needles, and melting at 150° with evolution of gas.

Salt.-B"H,Cl, 2aq. [150°]. Plates, liquefies c. 80° when quickly heated. .

Isodipiperideïne $C_{10}H_{18}N_2$. Formed by heating diazobenzene piperidide at 250° (Heusler, A. 260, 239). Thickish liquid, miscible with water, but can be extracted therefrom by ether. Reduces Fehling's solution and ammoniacal AgNO. Its salts are hygroscopic.

PIPERIDIC ACID C.H., NO. [184°], which is got by oxidising piperidine ν-carboxylic ether with fuming HNO, and heating the product with HClAq at 140°, is γ-amido butyric acid (Schotten, B. 16, 643; Gabriel, B. 23, 1770).

PIPERIDINE CHINN i.e.

CH. CH, CH, NH. Pyridine hexahydride. Mol. w. 85. (106°). S.G. 15 8664; 25 8591. M.M. 5·810 (Perkin, C. J. 55, 700). S.V. 108·76. S.H. 533 (Colson, Bl. [3] 3, 8). H.F.v. 24,090. H.F.p. 26,990 (Thomsen, Th. 4, 145). Appears to occur in the husks of pepper (Johnstone, C. N. 58, 235; An. 14, 41).

Formation. -1. By distilling piperine with potash-lime or soda-lime, or by boiling it with alcoholic potash (Wertheim, A. 127, 75; Anderson, A. 75, 82; 84, 345; Cahours, A. Ch. [3] 88, 76; Von Babo a. Keller, J. pr. 72, 53). 2. By reduction of pyridine in alcoholic solution by sodium-amalgam; the yield being 75 p.c. of the theoretical (Ladenburg a. Roth, A. 247, 51). 8. By heating pentamethylene-diamine hydro-chloride (Ladenburg, B. 18, 3100).—4. By heating hygric acid C₆H₁₁NO₂ with H₂SO₄ for a few minutes at 300° (Liebermann a. Kühling, B. 24,

Properties.—Liquid, with ammoniacal and peppery smell, miscible with water. Alkaline in reaction. Caustic taste. Ppts. salts of zinc and copper, but does not redissolve the ppd. hydrates. Not attacked by funing HClAq at 300° or by boiling HNO₄ (S.G. 1·5). Piperidine acts as an anæsthetic (B. 14, 713). Oxidised by H.O. to glutaric acid and its imide and δ-amido-valeric aldehyde (Wolffenstein, B. 25, 2777).

Reactions .- 1. Bromine and water at 200° yield di-bromo-oxy-pyridine and some CHBr, (Hofmann, B. 12, 984). Piperidine hydrochloride, heated with dry Br at 180, yields dibromo-pyridine (Schotten, B. 15, 427). Bromine and NaOHAq give crystalline C.H.Br.NO (Hof-mann, B. 16, 560). Bromine and lime-water yield bromo-piperidine C.H.,BrN [284°] (Lell-

mann, B. 22, 1327). -2. Chlorine acts with explosive violence on dry piperidine. In presence of water or chloroform it yields v-chloro-piperidine, which may also be got by using bleachingpowder. It is an unstable, heavy oil (52° at 25 mm.), with pungent odour, and deposits piperidine hydrochloride when kept for some time (Bally, B. 21, 1/72).—3. Conc. H.SO, at 800° forms pyridine (Kenigs, B. 12, 2341). Nitrobenzene at 260° also oxidises it to pyridine (L.). 4. Chloroform, on boiling for some days, yields 4. Choroform, on boiling for some days, yields CH(C₃H₁₀N)₃ aq (98° at 15 mm.) (Busz a. Kekulé, B. 20, 3'246).—5. CH₁CCl₃ forms, on boiling, ethenyl tripiperidine CH₂C(C₃H₁₀N)₃, a liquid (262°) yielding B"H₂Cl₃ and B"₂3H₂PtCl₃ (B. a. K.).—6. Boiling oxalic ether (1 mol.) yields piperidyl-oxamic ether C₃H₁₀N.CO.CO₂Et (289°) (Wallach, A. 214, 278; 237, 247). The corresponding axial March 11 coordinates of the corresponding axial March 12 coordinates of the corresponding axia sponding acid [129°] splits up on fusion into CO. and the formyl derivative of piperidine. PCI, yields CO₂ and C₂H₁₀N.COCI (238°), which acts upon piperidine forming (C₂H₁₀N)₂CO[43°] (298°). NH3Aq converts the ether into piperidyl-oxamide C₃H₁₀N.CO.CO.NH₂ [127°], crystallising in monoclinic prisms, converted by P₂O₃ into clinic prisms, converted by P₂O₃ into C₃H₁₀N.CO.CN, a heavy oil (264°). When piperidine (2 mols.) is distilled with oxalic ether (1 mol.) there is formed oxalyl-piperidine $C_3H_{10}N.CO.CO.C_1H_{10}N$ [89°] (above 350°).— 7. By heating with phthalic acid (2 mols.) as long as phthalic anhydride sublimes there is formed 'piperilene-amine-phthaleïn ' O18H21N2O2 or $C_0H_1<\frac{\hat{C}(NC_5H_{10})_2}{CO}$, an oil which yields crystalline C₁₈H₂₁Br₂N₂O₂ (Piutti, G. 13, 535; A. 227, 197).—8. Phthalic anhydride unites in the cold with piperidine, forming a mixture of ' piperilene-phthalamic acid' C_{H_10} N.CO. C_g H, CO. H_1 and its piperidine salt (P.). On shaking with other and water the acid goes into ethereal solution, and the salt into aqueous solution. Piper-

ilene-phthalamic acid is a heavy oil, v. sol. alcohol. It yields AgA', C.H., NHA' [c. 150°], and C18H28Br, N2O2, crystallising in long needles. 9. Alloxan and aqueous sulphurous acid give (C₁H₂N₂O₄)C₅H₁₁NH₂SO₃, crystallising in plates (l'ellizzari, A. 248, 150).-10. On heating with isatin and alcohol on the water-bath there is formed the compound C₈H₅NO(C₅H₁₀N)₂ or C_uH₄ C(NC₃H₁₀)₂, crystallising in flat colour-

less prisms, m. sol. hot alcohol, turned red by HCl, and yielding a blue dye (indigo 2) when treated with Ac₂O, or when rapidly heated to 125°-160°. Bromo-isatin forms, in like manner, C.H.BrNO(C.H.0N)2, crystallising in needles, while di-bromo-isatin reacts with production of C.H.Br. (NH.).CO.CO.NC. H. [152] (Schotten, B. 24, 1367, 2605).—11. A solution of diazobenzene chloride and sodium acetate forms Ph.N:N.NO, H10, which yields phenol and piperidine when treated with dilute H.SO., and phenyl-hydrazine and piperidine when reduced by SuCl, and HCl (Nölting a. Binder, B. 20, by Such and Hol (Noting a. Bines, B. 20, 3016). Other diazo-compounds act in like manner. Diazobenzene piperidide is decomposed on heating to 250°, yielding benzene, N, and isopiperidein (Heusler, A. 260, 239).—12. Potassium cyanate converts piperidine sulphate into NH₊CO.NC.H₁₄, crystallising from alcohol in needles (Cahours). Methyl and ethyl cyanates prisms [172°]. O,H,NH.COOl gives rise to O,H,NH.CO.NC,H, [102°], crystallising from dilute alcohol in needles (Kühn a. Riesenfeld, B. 24, 3818).—13. Methyl thio-carbimide forms NHMe.CS.NO₅H₁₀ [129°] (Hecht, B. 23, 287; 25, 815), while ethyl-, propyl-, and phenyl- thiocarbimides form corresponding thio-ureas [46°], [75°], and [99°] respectively. Phenyl-, o-, and p-tolylthiocarbimides form C3H10N.CS.NHPh [983] (G.); [104°] (Skinner a. Ruhemann, C. J. 53, 558) and C₃H₁₀N.CS.NHC,II, [98°] and [132°] respectively. Potassium sulphocyanide reacts with piperidine sulphate, forming C₃H₁₀N.CS.NH₂ [92°] Gebhardt, B. 17, 3039). Allyl-thiocarbimide forms oily C, H, N.CS.NHC, H, which is converted by conc. HClAq at 100° into C₃H₁₀N.C S.CHMe, a liquid (277°) yielding B'C H,N₃O, [112°] and B'MeI [67°] (Avenarius, B. 24, 262).—14. Benzoul-thiocarbimide added to a solution of piperidine in dry benzene forms C, H, N.CS.NHBz [123°], crystallising in needles, sol. alcohol and ether (Dixon, C. J. 55, 624). Benzyl-thiocarbinide gives C.H., N.CS.NHCH, Ph [88°] (Dixon, C. J. 59, 568).—15. Tri-methyl-trithiocyanurate at 200° forms C₁,H₂,N₃S [107°], which gives B'₂H₂PtCl_a (Hofmann, B. 18, 2779).—16. Quinone forms red needles [178°], which are probably C₆H₂O₂(NC₅H₁₀)₂ (Lachovitch, M. 9, 506).— 17. Benzoic aldehyde in presence of K₂CO₃ forms OHPh(NC₃H₁₀)₂ [80°] crystallising from alcohol in flat needles (Ehrenberg, J. pr. [2] 36, 130; Lachovitch, M. 9, 695).—18. Tri-oxy-methylene forms CH₁(NC, H₁₀)₂ (230°), which unites with CS₂ giving C₁(H₂₀N₂CS₂ [58°]. — 19. Pinene nitroso-chloride in alcoholic or aqueous solution yields crystalline C10H10NONC3H10 [119°] which forms B'HCl. The corresponding terpine and dipentinene derivatives melt at 154° (Wallach, A. 241, 320; 245, 253). -20. Amylene nitrosonitrate in boiling alcoholic solution forms CMe2(NC3H10). CMe: NOII, which crystallises from ether in prisms [96°], and is converted by boiling dilute H₂SO₄ into CMc₂(NC₅H₁₀).CO.CH₂, an oil (220°), μ_D = 1.934, volatile with steam, yielding a very hygroscopic hydrochloride (Wallach, Δ. 248, 172). -21. Fluorescein chloride at 220° forms $C_{\bullet}H_{\bullet}:C_{\bullet}O_{\bullet}$ $C_{\bullet}H_{\bullet}(NC,H_{\circ})$ O which yields $B''H_{\bullet}PtCl_{\bullet}$ and $B''H_{\bullet}Cl_{\bullet}$ which is purple in dilute solution and yellow in conc. HClAq (Lellmann a. Bütner, B. 23, 1387).—22. Bromo-phen-anthrene at 260° forms crystalline C₁₁H_oNC₂H₁₀ [113°] which yields B'₂H₂PtCl_a 6aq (L. a. B.).— 23. Bromo-anthracene at 260° reacts forming C_{1,}H_aNC₃H₁₀ crystallising from other in yellow prisms and giving B'₂H₂PtCl₅ 2aq (L. a. B.).— 24. Chloro-acetic acid forms C₃H₁₀N.CH₂CO₂H, which forms hemihedral prisms (containing aq) and yields CuA', 4au, HA'HCl, HA'HBl, (HA'),3HAuCl, and HA'BaCl, (Kraut, A. 157, 66).—25. a-Chloro-propionic ether produces C.H., N.CHMe.CO.H crystallising from water and alcohol in prisms and yielding HA'HAuCl, acconol in prisms and yielding HA'HAuCl, (Brühl, B. 9, 34).—26. Benzene sulphochloride and NaOHAq form C.H., SO, NC.H., [93°] (Hinsberg, A. 265, 182; Schotten a. Schlömann, B. 24, 8689). This body is oxidised by KMnO, to O.H., SO, NH.CH., CH., CH., CO.H..

yield corresponding ureas. Phenyl cyanate forms NHPh.CO.NO, H., or crystallising from alcohol in

27. Picryl chloride forms C.H., N.C.H. (NO.). [106°] (S. a. S.).—28. Glycerin dichlorhydrin forms liquid O₁H₂N₂O (280° 290°) which yields B"H₂PtCl_a (Ladenburg, B. 14, 1879).—29. CS₂ forms (O₂H₁N₁O₂O or O₂H₁N₁OS.SNO₂H₁, crystallizing analysis [174] tallising in slender monoclinic needles [1740]. converted by an alcoholic solution of iodine to (C₃H₁₀N.CS)₂S₂[130°]. — 30. Dicyandiamide reacts on 'piperyl-biguanide' with formation of C,H₁₅N₅, on 'piperyl-bignanide' with formation of C,H₁,N₂, c. C,H₁, N, C(NH), NH, C(NH), NH, [163° 7] orystallising in silky needles, and yielding the salts B'H,Cl₂ [2170], B'H,SO, [173°], B'H,SO, [219°], B'H,PiCl₂ [252°], B'H,AuCl₃, and the copper compound Cu(C,H₁,N₃,H,SO₄ crystallising in rose-red needles (Bamberger, B. 24, 605, 904). Piperyl-biguanido is converted by CHCl, and caustic potash into 'piperyl-formoguanamine' $C_1H_{10}N.C \leqslant N.C(NH_2) > N$ [194.5°] which yields N=CH
the salts B'HCl [201°], B'.H.SO.aq [222°],
B'2C,H.N.O. [A88°], B'.H.PtCl, [219°], B'HAuCl,
[90°] and [158°], and B'.AgNO, [229°-238°]
(Hjelt, B. 25, 529). Piperyl-bignanide sulphate heated with NaOAc at 200° yiells piperyl-aceto-guanamine C₃H₁₀N.C N:CMe N: [179°] (Hjelt, B. 25, 533). The acetyl derivative of piperyl-biguanideC₃H₁₆N.C(NAc).NH.C(NH).NH₂ [193°] is got by heating the copper salt with HOAc.

Salts.—B'HCl. [237°]. M.M. 10 034 in a 53 p.c. solution (Perkin, C. J. 55, 716). Needles, v. sol. water and alcohol. -B'HAuCl, [206°]. Not decomposed by boiling water (De Coninck, Bl. [2] 45, 131). B', H.PtCl, [196°] (Ladenburg, B. 18, 3100); [200°] (Wallach a. Lehmann, A. 237, 241). Red needles. Not decomposed by boiling water (De Coninck, Bl. [2] 45, 131). Crystallises also with EtOH in orange needles [191°]. - B'₂PtCl₂. B'Zn OCl2: amorphous pp. got by adding piperidine to a solution of ZnCl2 (Lachovitch, M. 9, 517) .- B'HBr. Plates (Lellmann, B. 20, 680) .-B'HI. Long needles.—(B'HI), 2BiI, Scarl plates (from alcohol) (Kraut, A. 210, 819). Scarlet B'ICL [143°]. White needles. - B'ICIHCl. BTCI. [143°]. White nection.—BICHCI. [190°]. Yellow crystals (from water) (Pictet a. Krafit, Bl. [3] 7, 72).—B'HNO., Small needles.—B'.H.C.O.; needles.—B'.H.FcCy, 3aq. Yellow triclinic crystals.—Piperate B'C₁₂H.₁₀O., Silky lamine [100°] (Babo a. Keller).—B'.H.₂SO., Nitrosamine C.H.₁₀N.NO. (218°). S.G.

185 1-066. Formed from piperidine and nitrous acid (Wertheim, A. 127, 75; Schotten, B. 15, 425; Knorr, A. 221, 298). Pale-yellow liquid, 8l. sol. water, v. sol. conc. HClAq, but reppd. on dilution. Zinc and HClAq reduce it to piperidine and NH₁. Heated in a current of HCl at 100° it gives piperidine and NOCl. Sodium-amalgam forms C₂H₁₀N.NH₂ and piperidine.—B"H₂Cl₂: syrupy.—*B"HCl: crystalline mass.

Hydrazine C.H., N.NH. Piperyl-hydrasreducing the nitrosamine with zinc-dust and HOAc (Knorr, B. 15, 859; A. 221, 299). Liquid, with ammoniacal odour, miscible with water, alcohol, and ether. Volatile with steam. Oxidised by HgO in the cold to the tetrazone C₁₆H₂₀N₄ [45°], which yields B'₂H₂PtCl₃. Reduces cold ammoniacal AgNO, and hot Fehling's solution. Nitrous acid converts it into piperidine. CS, gives rise to (C,H,eN.NH),CS [181]. The compound

C.H.o.NH.CS.NC, H.o [86°] may also be obtained. BzOl in ether forms C,H₁₀N.NHBz [196°]. Benzole aldehyde forms C,H₁₀N.N:CHPh [63°]. Salt.—B'HCl. [162°]. Tables (from alcohol). Reacts with potassium cyanate forming $C_bH_{10}N.NH.CO.NH$, [136°] and with potassium sulphocyanide forming CAHION.NH.CS.NH. [167°].—Methylo-iodide B'Mel.[215°]. Begins to decompose at 150°.

Formyl derivative C,H, N.CHO. (222°). 8.6. 23 10193. Formed by the distillation of $C_5H_{10}N.CO.CO.H.$ (v. Reaction 6) (Wallach a. Lehmann, A. 228, 251; 237, 252). Got also by heating piperidine with formamide (Lachovitch, M. 9, 699). Liquid, miscible with water, alcohol, and ether. PCl, yields a base C11H20N2- B'HCl:

and ether. For young abserting and states are deliquescent needles. — B', H, PtCl. [172°]. Plates.—B'HgCl. [149°]. Needles. Acetyl derivative C, H, Nac. (227°). S.G. 2 1011 (Wallach a. Kamensky, A. 214, 238; cf. Schotten, B. 15, 426). Liquid, miscible with water. When heated with BzCl it gives AcCl and benzoyl-piperidine (Pietet, B. 23, 3014). On heating with bromine it gives pyridine, bromo-pyridine, and di-bromo-pyridine (Hofmann, B. 16, 587). When Cl is passed into cooled acetyl-piperidine and the product is warmed with water, there is formed C,H₁₁Cl₂NO₂

[122°] (Bally, B. 21, 1772).

Benzoyl derivative C,H₁₀NBz. [48°]. (above 360°). Formed from piperidine, BzCl, and NaOHAq (Cahours; Schotten, B. 17, 2544; 21, 2238). Triclinic prisms (from alcohol). Oxidised by KMnO, to benzoyl-8-amido-valeric acid dised by KMnO, to benzoyl-6-amido-valeric acid [94°]. Benzoic aldehyde forms the compound NH C(CHPh).CH₂>CH₂ [89°], which yields B'HCl [166°] and B'HNO₃ [98°], both being crystalline (Rügheimer, B. 24, 2186).

Bromo-benzoyl derivative CaH10N.CO CaH4Br. The o-compound is an oil, while the p-compound crystallises from alcohol in rectangular monoclinic tables [95°] (Schotten,

B. 21, 2248).

m-Nitro-bensoyl derivative

C.H. N.CO.C. H. NO₂. [34°]. (184° at 54 mm.). S. (alcohol) 33 in the cold, 50 at 78°. Darkyellow monoclinic crystals. Crystallises from water with about 5aq, and then melts at 84°. Yields, on reduction, the m-amido-benzoyl derivative [125°].

Oxy-bensoyl derivative v. Piperidide

of OXY-BENZOIC ACID.

Cuminyl derivative C15H21NO. Tables. Cinnamyl derivative C, H, CO.NC, H10. • [122°]. Formed from the anhydride and piper-idine (Herstein, B. 22, 2265). Stellate needles.

Alkyl-piperidines. On heating the alkylo-iodides of pyridine, a pair of alkyl-pyridines is produced, that of lower boiling-point being (a)-alkyl-pyridine, and the other (γ) -alkyl-pyridine. On reduction these give the corresponding alkyl-piperidines. The same isopropyl-pyridines are obtained both from pyridine isopropylo-iodide, and pyridine n-propylo-iodide, an intramolecular change taking place in the propyl group in the latter case. Conyrine is (a)-propyl-pyridine, conline is (a)-propyl-piper-idine (Ladenburg, B. 18, 1587). By adding potash to piperidine alkylo-iodides, r-alkylpiperidines can be obtained.

Methyl-, Ethyl-, Propyl-, Phenyl-, and Tolyl-Piperidines v. METHYL, ETHYL, PROPYL, PHENYL, and Tolyl Pyridine HEXAHYDRIDES.

PIPERIDINE p-CARBOXYLIC ACID

CH₂CH₂CH₂N.CO₂H. Methyl ether MeA'. (201°). Formed from piperidine, ClCO₂Me, and Honry KOHAq (Schotten, B. 15, 425; 16, 647). Heavy oil. Converted by HNO, containing urea, into C,H,(NO,)N.CO,Me [103°], whence Br forms a compound [130°].

Ethyl ether EtA'. Piperul-urethane. Ethyl ether EtA'. Pyreyyl-urcunane.
(211°). Formed from piperidine and ClCO₂Et.
0il. Br in HOAc forms C.H.B.N.CO₂Et [140°],
while HNO, free from NO₂ forms 'nitrodehydropiperyl urethane' C₃H₁(NO₂)N.CO₂Et [52°],
whence Br in HOAc forms C.H.B.N.O₂, [157°].
Chloride C.H.₁₀N.COCl. (238°). Formed
from C.H.₁₀N.CO.CO.H and PCl, (v. PIPERIDIER,
Paration (1) Liquid shouly decomposed by cold

from C₂H₁₀N.CO.CO.H and PCl₄ (p. PIPERIDINE, Reaction 6). Liquid, slowly decomposed by cold water into piperidine, CO., and HCl.

Amide C.H.₀N.CO.NH.₂ [106°]. Got from piperidine sulplate and potassium cyanate.

Needles. Yields B'HNO., [67°] (Franchimont a. Klobbie, R. T. C. 8, 302).

Anilide. [172°]. Formed from piperidine and phenyl cyanate, or from the chloride and aniline (Gebhardt, B. 17, 3010; Wallach, A. 228, 250; 237, 250).

Piperidide (C.H., N), CO. [43°].
Isomeride v. Hexahydride of Pyriding CARBOXYLIC ACID.

DI-PIPERIDYL v. DIPYRIDYL dodecahydride

PIPERIDYL-CYANURAMIDE v. Cyanuramide in article Cyanic Acids.

PIPERIDYL-MELAMINE v. CYANIC ACIDS.

PIPERILENE v. vol. iii. p. 807.

PIPERILENE v. vol. iii. p. 807.

PIPERINE C. H. 10 NO. i.e.

C. H. 10 N. CO.C.H. C.H. C.H. C.H. C. H. 20 C.H. 2. Piperylpiperiline. Mol. w. 285. [128°]. Occurs in
black pepper (Piper nigrum), long pepper (P. longum), and in the black pepper of Western Congun), and in the black pepper of Western Africa (Cubeba Clusii) (Oersted, S. 29, 80; Pelletier, A. Ch. [2] 16, 344; 51, 199; Merck, N. J. T. 20, 1, 34; Wackenroder, Br. Arch. 37, 347; Duflos, S. 61, 22; Warrentrappa. Will, A. 39, 283; Wertheim, A. 70, 58; Gerhardt, Compt. Chim. 1849, 375; A. Ch. [3] 7, 253; Anderson, A. 75, 82; 84, 345; Cahours, A. Ch. [3] 38, 76; Staphones, A. 95, 166; Von Behoe, Kelley, Lee Stenhouse, A. 95, 106; Von Babo a. Keller, J. pr. 72, 53; Strecker, A. 105, 317).

Formation .- By heating piperidine with the chloride of piperic acid (Rügheimer, B. 15, 1390).

Preparation. - Ground pepper (1 pt.) is boiled with slaked lime (2 pts.) and water, the filtrate evaporated to dryness at 100°, and the piperine extracted with ether and recrystallised from alcohol (Cazeneuve a. Caillot, Bl. [2] 27, 290).

Properties .- Monoclinic prisms, v. sl. sol. hot water, m. sol. alcohol and ether. Inactive to light. Insol. dilute acids and alkalis. Decomposed by alcoholic potash into piperic acid and piperidine. Conc. H.SO, forms a blood-red solu-tion. HNO, gives a greenish-yellow colour changing to red. Phosphomolybdic acid gives a flocculent pp. Salts.—The hydrochloride is crystalline,

but decomposed by water.—B',H,PtCl,: roseate monoclinic crystals. Not decomposed by hot water (De Coninck, Bl. [2] 45, 131).—B', HHgCl, : triclinic crystals. -B'HI. r145°7. Steel-blue needles (Jörgensen, J. pr. [2] 3, 328).
PIPEROKETONIC ACID v. DI-OXY-BENZYL

ETHYL KETONE CARBOXYLIC ACID.

PIPERONAL v. Methylens derivative of PROTOCATECHUIC ALDEHYDE.

PIPERONYL-ACRYLIC ACID v. Methylene ether of CAFFEIG ACID.

PIPERONYL ALCOHOL v. Methylene derivative of DI-OXY-BENZYL ALCOHOL.

PIPERONYLIC ACID v. Methylene derivative of PROTOCATECHUIC ACID.

PIPEROPROPIONIC ACID v. DI-OXY-PHENYL-

PIPER-PROPYL-ALKINE v. OXY-PROPYL-PIPERININE.

PIPERYL. This name is given to radicle CH2O.:C8H3.CH:CH.CH:CH.CO. Piperyl has also been used to denote C, H10, the divalent radicle which is united to NH in piperidine; many of the derivatives of this divalent 'piperyl' are described under PIPERIDINE.

PIPERYLENE v. Pentinene.
PIPERYLENE TETRABROMIDE v. Tetra-BROMO-PENTANE

PIPITZAHOIC ACID C₁₃H₂₀O₃. Perezone. [104°] (A. a. L.); [107°] (Mylius, B. 18, 480). May be extracted by alcohol from Pipitzahuae root or Radix Peresia (De la Sagra, C. R. 42, 873, 1072; Weldt, A. 95, 188; Anschütz a. Leather, C. J. 49, 715; B. 18, 709, 715). Flat golden plates (from alcohol), nearly insol. water, v. sol. alcohol and ether. May be sublimed. Volatile with steam. Aqueous alkalis form a violet solution. Aqueous methylamine forms methyl - amido - pipitzahofo acid C₁₅H₁₉(NIIMe)O₂ [114°], crystallising in blue needles, while aniline forms C₁₅H₁₉(NHC·H₂)O₂ [139°], o-toluidine gives C₁₅H₁₉(NHC·H₂)O₄ [110°] a toluidine gives C₁₅H₁₉(NHC·H₂)O₄ [110°], p-toluidine yields p-tolyl-amido-pipitzahore acid [134°]. Bromine forms C12H. Br.O2 [109°].

Salts.-PbC15H18O2.-CuA'2.-AgA': purple

Ethyl ether EtA'. [141°].

Acetyl derivative C_{1.}H₁₉AcO₃. [115°]. Trimetric plates; a:b:c=629:1: 845.

Oxim? C_{1.}H₂₁NO₃. Amidopipitzahoic acid.

[154°]. Flat violet-brown needles. Formed from the scid and alcoholic hydroxylamine (Mylius, B. 18, 936). The same body is got by boiling phenyl-amido-pipitzahoïe acid (v. supra) with NH₂Aq (A. a. L.).

Oxypipitzahoïc acid C_{1,}H_{1s}(OH)₂O₂. [129'] (A. a. L.); [134°] (M.). Formed by warming phenyl-amido-pipitzahoïc acid (v. supra) with alcoholic H.SO. Orange plates, nearly insol. water. Its alkaline solutions are violet. Bromine forms an unstable dibromide [140°-146°]. On warming with H₂SO₄ it is converted into perozinone O₁₅H₁,O₂ [144°], which crystallises in yellow needles or prisms, and yields C15H1, NaO2, crystallising in easily soluble yellow tables.

PIRYLENE C.H. i.e. $CH \ll_{CH:CH^2}^{CH,CH_2}$. (60°).

Formed by distilling with solid NaOH the methylo-iodide of the base obtained by the action of Ag.O on the iodide formed from di-methyl-pyridine hexahydride and iodine (Ladenburg, A. 247, 60). Oil. Does not ppt. ammoniscal Ou,Ci,

PISCIDIN C., H.,O. [192°]. The poisonous principle of Jamaica dogwood (Piscidia Erythrina), from which it can be extracted by lime-water (Hart, Am. 5, 39). Six-sided prisms (from alcohol), insol. water, sl. sol. cold alcohol, sol. benzene, CHCl., and conc. HClAq. Sedative and narcotic.

PITTAKAL v. EUPITTONIC ACID.

PITURINE is NICOTINE.

PLASMINE v. PROTEÏDS.

PLATINAMMINES v. PLATINUM-AMMONIUM сомроимов, р. 292.

PLATINATES. Pto II, acts as an acidio hydroxide towards strong bases, forming compounds of the type xPtO2.yMO. These platinates are generally obtained by reacting on PtCl, Aq with caustic or carbonated alkalis, and sometimes by fusing PtCl, with bases and then washing with water.

Barium . platinates. 2PtO...3BaO was obtained, in hexagonal crystals, by Rousseau (C. R. 109, 144) by heating PtCl. with BaO for some time, then adding BaCl, equal to the quantity of BaO used, and heating to c. 1100° (m.p. of Cu) in a Pt dish for some hours, and washing with water. The crystals are insol. acetic acid, but sol. HClAq. The salt decomposes at an orange-red heat, in presence of BaCl₂, with separation of Pt. Topsöe (B. 3, 462) obtained PtBaO₃.4H₂O by decomposing H2PtCl, Aq by excess of BaO2H2 in sunlight; to the pp. thus obtained Johannsen (A. 155, 204) gave the composition

3PtBaO3.BaCl2.PtOCl2.11H2O.

Calcium platinates. According to Herschel (A. 3, 317), CaOAq added to PtCl, Aq in sunlight produces a white pp. of

PtCaO3.CaO.PtOCl2.7H2O.

Sodium platinates. When a mixture of Na₂CO₃Aq and H₂PtCl₈Aq stands for some days in a warm place, a pp. of 3PtO2. Na O.6H,O separates (Döbereiner a. Weiss, A. 14, 21). Rousseau (C. R. 109, 144) obtained crystals of Na platinate by heating a mixture of equal weights of NaOH and NaCl with some Pt black, in a Pt crucible, to c. 1100 for two or three hours.

For descriptions of the bromoplatinates, chloroplatinates, iodoplatinates, &c., v. Platini-BROMIDES, PLATINI-CHLORIDES, PLATINI-IODIDES,

THIOPLATINATES. PtS, combines with some more basic sulphides to form salts which may be called thioplatinates; some salts are also known containing Pt and Sn combined with alkali metal and S, these may be called thiostanuoplatinates. The alkali thioplatinates are obtained by fusing together spongy Pt, S, and alkali carbonate, and washing with water, wherein the thioplatinates are insoluble. Other thioplatinates - of Cd, Cu, Fe, Pb, Mn, Hg, Ag, Tl, Platinates—or Cd, Cd, Fe, Fe, Mi, Hg, Ag, Ag, Sr, and Zn—arc obtained by double decomposition from the alkali salts. The thioplatinates belong to the forms M¹_Pt_sS_and M⁴_Pt_sS_a; the corresponding thioplatinic acids H_Pt_sS_a H,Pt,S, are obtained by decomposing K,Pt,S, and Na,Pt,S, respectively by dilute HClAq.

Potassium thioplatinate K.Pt.S. = K.S.3PtS.PtS. (Potassium platin-thioplatinate). Blue-grey, metal-like crystals; S.G. 6:44 at 15°. Glows like tinder when heated in air, forming K,SO, and Pt; reduced in H with

evolution of H_sS and formation of Pt. Obtained by fusing an intimate mixture of 1-2 parts Pt black with 12 parts of a mixture of equal parts of S and K_sCO_s in a porcelain crucible, keeping the molten mass over the blowpipe for a few minutes and extracting with water when cold.

Sodium thioplatinate

Na,Pt,S,=2Na,S.2PtS.PtS, (Disodium platinthioplatinate). Copper-red, rhombic needles; decomposed in air. Obtained similarly to the K compound mentioned above.

For details regarding thioplatinates, and also thiostannoplatinates, v. Schneider, P. 136, 105; 138, 604; 139, 661; 141, 519; 148, 633; 149, 881 (cf. E. von Meyer, J. pr. [2] 15, 1).

PLATINITES, derivatives of; v. Platino-BROMIDES, PLATINO-CHLORIDES, PLATINO-NITRITES, &co.

PLATINI- and PLATINO- GOMPOUNDS. Such compounds as platini-bromides, called also bromoplatinates, and platino-nitrites will be tlesorthed here.

PLATINI. COMPOUNDS. These compounds are derived from platinic compounds, especially from PtCl, PtBr, and Ptl, they generally react as salts of acids containing tetravalent atoms of Pt in their acidic radicles.

Platini-bromhydric acid H₂PtBr₂.9H₂O (Bromoplatinic acid). Formed by heating spongy Pt with Br, and HBrAq (b.p. 126°), in a sealed tube, to 180° (Meyer a. Züblin, B. 13, 404; Halberstadt, B. 17, 2962). Also by dissolving Pt black in HNO₃Aq mixed with HBrAq, heating with repeated additions of HBrAq, evaporating over CaO, and washing the crystals, on an asbestos filter, with CS₂ (H., l.c.). Large, clear, carmine-red, monoclinic crystals; v. sol. water, alcohol, ether, acetic acid, and CHCl₂. Melts at 100° with partial decomposition (Topsüe, Ar. Sc. 35, 58; 45, 223).

50, 58; 40, 220;.

Platini-bromides M'.PtBr. (Bromoplatin.
ates). Thomsen (Th. 3, 430) gives [Pt, Br, 2RBrAq]

= 57,160 and [Pt, 0°, 6RBrAq] = 80,360, where
R = H, Na, K, Am, \(\frac{1}{2}\text{Ca}, \(\frac{1}{2}\text{Ba}, \(\frac{1}{2}\text{Sr}, \(\frac{1}{2}\text{Mg}, \) These
salts are generally formed by evaporating
H.PtBr.Aq, or a solution of Pt in Br and
HBrAq, with metallic bromides. They are red
crystalline solids, isomorphous with the corresponding Cl salts. As solutions of these salts
give a pp. of Ag.PtBr. and not AgBr, with a
limited quantity of cold Ag.NO.3Aq, and on electrolysis of their solutions the Pt goes with
the Br to the positive electrode, they are better
regarded as ordinary salts than as double salts
2MBr.PtBr.

AMMONIUM PLATINI-BROMIDE Am,PtBr. Red cotahedra; S.G. 4-2; sl. sol. cold water. S. at 20° = 59 (Halberstadt, B. 17, 2962). Formed by evaporating H,PtBr,Aq + NH,Br.

POTASSIUM PLATINI-BROMIDE K,PtBr. Red octahedra; S.G. 4.54 (Topsöe, Ar. Sc. 35, 58; 45, 228). S. 2.07 at 20°, 10 at 100° (H., l.c.). Obtained by ppg. H,PtBr,Aq by KBr, or by evaporating H,PtCl,Aq with KBr. Thomsen (Th. 8, 480) gives [Pt,Br,2KBr] = 59,260; [K*PtBr*Aq] = -12,260.

Double compounds with K.PtCl, are described by Pitkin (C. N. 41, 118).

Sonium Platini-Bromide Na,PtBr.,6H.O. Dark-red, triolinic prisms; S.G. 3-323; very sol.

water and alcohol. Obtained by evaporating PtCl, Aq with HBr till the Cl is turned out, adding NaBrAq, evaporating to dryness, dissolving in a little water, and crystallising (Thomsen, J. pr. [2] 15, 294). Thomsen (Th. 3, 480) gives [Pt,Br*,2NaBr,6HO] = 65,830; [NaPtBr*,6H*O] = 18,540; [NaPtBr*,6H*O,Aq] = -8,550. Platini-bromides of Ba with 10aq, Ca with 12aq, Co with 12aq, Cu with 8aq, Ph. Mg with 12aq, Mn with 12aq, Ni with 6aq, Sr with 10aq, and Zn with 12aq, are described by Topsöe (Ar. Sc. 35, 58; 45, 223); von Bonsdorff (P. 19, 343) describes a Mn salt with 6aq.

Platini-bromonitrites (Nitro-bromoplatinates. Platini-nitrobromides). Salts derived from the platini-bromides by replacing Br by NO. Bygently heating K.pt(NO.). (v. Platino-nitrites, P. 284) with Br. polassium platini-dibromonitrite, K.ptBr.(NO.)., is obtained as a yellow powder, sl. sol. cold, more sol. hot, water (Vèzes, C. R. 112, 616). When an aqueous solution of this salt is concentrated at a gentle heat, it yields crystals of potassium platini-tribromonitrite, K.ptBr.(NO.). (V. C. R. 115, 44). Polassium platini-tetrabromonitrite, K.ptBr.(NO.).; is obtained by the regulated action of Br on K.pt(NO.).; it forms red prisms, sol. water with partial decomposition (V., C. R. 115, 44).

Platini-chlorhydric acid H,PtCl,.6H.O (Chloroplatinic acid). A solution of this compound is the starting-point for the preparation of very many Pt compounds. Formed by dissolving Pt in aqua regia, repeatedly evaporating with cone. HClAq till every trace of HNO, is expelled, and allowing to crystallise (Weber, P. 131, 441; Jörgensen, J. pr. [2] 16, 345; Topsöe, Ar. Sc. 35, 58). Red-brown, very deliquescent crystals; S.G. 2-431. Easily sol. alcohol, forming crystals; S.G. 2-431. Easily sol. alcohol, forming H.PtCl_(OEt), (Schützenberger, A. Ch. [4] 31, 362). Heated to 230', gives PtCl, (v. Platinum digitioning, Freparation, p. 289). Heated in Cl to above 350' gives PtCl, (v. Platinum tetral-cultoride, Formation, p. 289). By adding much H_SO, to H_PtCl_oH_O in a little water, Pigeon (C. R. 112, 1919), abtained the heater (1). (C. R. 112, 1218) obtained the hydrate with HI,O; and by heating in vacuo at 100°, over fused KOH, he obtained HPtCl, 2H,O. Thomsen (Th. 3, 430) gives [2HClAq,Pt,Cl] = 84,620; [6HClAq,Pt,Cl] = 64,660. Pigeon (C.R. 110,77) gives [H-PtCl*-6HTO,Aq] = 4,340. H.PtCl*Aq reacts as a dibasic acid; the platinic-hlorides are numerous and important; the Am and K salts are only sl. sol. water and insol. alcohol, and are much used as forms for estimating K and ammonia. Very many organic bases replace H and form salts analogous with the metallic platinichlorides.

Platini-chlorides M¹-PtCl_s (Chloroplatinates),
Thomsen (Th. 3, 430) gives [Pt,Cl¹,2RClAq]
=84,620; and [Pt,O¹,6RClAq]=64,060; where
R=H, Am, K, Na, 3Ba, 3Ga, 3Sr, 3Mg. Pigeon
(C. R. 110, 77) gives [PtCl¹,2HClAq]=24,800.
These salts are generally obtained by evaporating
H,PtCl,Aq with metallic chlorides. Most of
them are yellow-red, crystalline solids; usually
e. sol. water and alcohol. They are better
regarded as ordinary salts than as double chlorides (cf. Platini-browides, supra). The platinichlorides were investigated by von Bonsdorff
(P. 17, 250); later by Cleve (Bl. [2] 21, 118, 197,
247, 845); also by Tope6e (Ar. So. 85, 58); and

by Nilson (B. 9, 1056, 1142). Crystallographically considered, these salts fall into four groups:—(1) M.PtCl, where M = Am, Cs, K, Rb, Tl (and Pt may be replaced by Pd, Ir, or Sn); regular, isomorphous with Am2(or K2)PtBr2, Am, (or K,)PtI,, fluosilicates, fluostannates, fluozirconates of similar composition. (2) MPtCl. 6aq, where M = Cd, Co, Cu, Fe, Mg, Mn, Ni, Zn (and Pt may be replaced by Pd or Sn); hexagonal. (3) MPtCl₆.12aq, where M = Mg or Mn; hexagonal; isomorphous with corresponding platini-bromides.
(4) M(PtCl_{*})₂·24aq, where M = Ce₂ or La₂; hexagonal.

Ammonium Platini-chloride Am2PtCla (Ammonium chloroplatinate. Platinsalammoniac). Ppd. on adding NH,Cl to H,PtCl,Aq, PtCl,Aq, or a solution of Pt in cone. HClAq with a little a solution of Pt in cone. Florid with a fittle HNO₂. Yellow, regular, octahedral crystals. S.G. 3-065 (Topsöe, l.c.). S. -665 at 20°, 1-25 at 100° (Michaelis, G.-O. 1, 1187). Scarcely sol. alcohol or ether. Decomposed at red heat, leaving Pt black. For reactions with NH₃ v. PLATINUM-AMMONIUM COMPOUNDS, p. 292.

POTASSIUM PLATINI - CHLORIDE (Potassium chloroplatinate). Ppd. by adding KCl, or other K salt, to conc. H₂PiCl₈Aq, or to a solution containing Pt which has been evaporated with excess of HČlAq. Reddish-yellow regular octahedra. S.G. 3-586 (Bödeker). S. 74 at 0°, 1-12 at 20°, 2-17 at 50°, 3-79 at 80°, 5-13 at 100° (Michaelis, *l.c.*). Almost insol. alcohol, or alcohol and ether. Slightly sol. dilute acids; sol. KOHAq. Reduced to Pt and KCl by heating to redness; more quickly by heating with reducing agents such as oxalic acid or sulphurous acid, or by heating in a stream of hydrogen. Vèzes (C. R. 110, 757) describes a nitroso- derivative, (C. R. 110, 757) describes a narrows derived $K_2Pt(NO)Cl_5$. Pigeon (C. R. 110, 77; 112, 791) gives [Pt,Cl',2KClAq] = 83,330; [PtCl',2KClAq] = 95,330; [PtCl',2KClAq] = 95,330; [PtCl',2KCl] = 29,700. Thomsen (Th. =25,330; [PtCl $^{4},2$ KCl] =29,700. 3, 430) gives [Pt,Cl4,2KCl] = 89,500.

Potassium platini-bromochloride K2PtBr2Cl4; by ppg. H2PtCl6Aq by KBr (Pitkin,

C. N. 41, 118).

The following platini-chlorides have also been isolated: AlCl. PtCl. 15aq (Welkow, B. 7, 804; Salm-Horstmar, P. 99, 638); Ba, with 4aq (Topsöe; Bornsdorff, Precht, Fr. 1879; 509); Be, with 8aq (Welkow, B. 6, 1288; Thomsen, B. 3, 827); Cd, with 6aq (Topsöe); Cs (Crookes, C. N. 9, 37; Bunsen, P. 119, 371); Ca, with 9aq (Topsöe); Breath! (Topsöe; Procht); Ge, various salts (Cleve, Marignae, Holzmann, J. pr. 81, 80); CrCl, PtCl, 10aq (Nilson, B. 9, 1056, 1142); Co, with 6aq (Topsöe); Cu, with 6aq (T.); Di, various salts (Frerichs a. Smith, A. 191, 331); 2InCl, 5PtCl, 36aq (Crookes, J. 1864. 256); Fe, various salts (T.; Bonsdorff; various salts (Cleve, Marignac, Nilson); La, Jolin, B. 11, 910); Pb, with 3 or 4aq (Birnbaum, J. 1867. 319; Topsöe); Li, with 6a4 (Scheibler, J. pr. 67, 485; Jörgensen a. Topsöe, Gm.-K. 3, 1174); Mg, with 6aq (T.); Mn, with 6aq (T.); Ni, with 6aq (T.); Rb (Crookes; Bunsen); Ag (Birnbaum); Na, with 6aq (Marignao, Topace, Precht; for thermal data v. Thomsen, and Pigeon, Le.); Sr, with 8aq (Bonsdorff); Tl rigeon, 4.5.; or, with 12aq (Cleve); Sn, with 12aq (Cleve); Sn, with 12aq (Cleve); Sn, with 12aq (Nilson). Compounds of PtCl, with chlorides of Rr (Nilson), Hg (Birnbaum), VO (Brauner, M. 3, 58), and ZrO (Nilson) probably exist. No com-

pounds are formed with PtCl, and chloride of Sb, As, or Bi.

(Platini-nitrochlor-Platini-chloronitrites Nitrochloroplatinates). Salts derived from the platini chlorides by replacing Cl by NO. A few of these salts are described by Vèzes (C. R. 115, 44); the principal are dichloronitrite K.PtCl₂(NO₂), trichloronitrite K.PtCl₂(NO₂), and pentachloronitrite K.PtCl₃(NO₂). H₂O (v. also Blomstrand, J. pr. [2]

3, 214). Platini-iodhydric acid H,PtI,9H,O (Iodoplatinic acid). Brown deliquescent crystals; probably monoclinic; by dissolving PtI, in HIAq, and evaporating. Easily decomposed, even in solution, rapidly at 100°, with separation of PtI, (Topsoc, Ar. Sc. 38, 297; Clementi, J. 1855. 420; Lassaigne, A. Ch. [2] 51, 113).

Platini-iodides Mr.PtI. (Iodoplatinates). Reddish-brown, metal-like salts; generally formed by evaporating H.PtCl.Aq with excess of (Iodoplatinates). metallic iodides, or by adding iodides to PtI Aq. The following have been described (v. Topsöc, Clementi, Lassaigne, l.c.; Am; Ca, with 12aq; Co; Fe; Mg, with 9aq; Mn; Ni, with 6aq; K; Na, with 6aq; Zn, with 9aq.

Platini-iodonitrites (Platini-nitro-iodides. Nitro-iodoplatinates). $M_2^1PtI_{e-x}(NO_2)_x$. A few of these salts are described by Vezes (C. R. 113, 696). A nitroso-platini-iodide, K,Pt(NO)I,, is

also described.

By boiling Pt(OH,) Platini-molybdates. with an acidified solution of Na molybdate, Gibbs (Am. S. [3] 14, 61) obtained a complex compound which may provisionally be classed as a platini-molybdate, 4Na,O.10MoO, PtO, 29H,O.

Platini-nitrobromides ; .v. PLATINI-BROMOмититея, р. 282.

Platini-nitrochlorides; v. PLATINI-CHLORO-NITRITES, supra.

Platini-nitro-iodides; v. PLATINI-IODO-NITRITES, supra.

Platini-tungstates. Complex compounds of PtO2, WO3, and strong bases (v. Gibbs, Am. S. [3] 14, 61; Rosenheim, B. 24, 2397).

These com-PLATINO. COMPOUNDS. pounds are derived from platinous compounds, especially from PtCl., PtBr2, and PtI2; they generally react as salts of acids of the form H2PtX4, where X is a monovalent negative radicle, generally Cl, Br, or I.

Platino-bromhydric acid H₂PtBr. (Bromo-tinous acid). This compound is probably platinous acid). contained in a solution of PtBr, in HBrAq.

Platino bromides M1.PtBr. (Bromoplati-nites). Only one of these salts, K.PtBr., has been isolated. Potassium platino-bromids is obtained by adding a very little water to a mixture of the corresponding Cl salt and NaBr, in the ratio K,PtCl,: 4NaBr, boiling, sucking up the clear liquid from ppd. NaCl, and allowing to cool, when the salt crystallises in dark-brown octahedra, or brown-red needles, which are very sol. water (Thomsen, J. pr. [2] 15, 294). Thomsen (Th. 3, 430) gives [2KBr, Pt, Br²] = 82,310.

Platino-bromonitrites v. Platino-mitrites, p. 284.

Platino-chlorhydric acid H.PtCl, (Chloroplatinous acid). This soid has not been isolated; but it almost certainly exists in a solution of PtCl, in HClAq, in the liquid obtained by decomposing BaPtCl, by the equivalent quantity of H₂SO,Aq (Nilson, J. pr. [2] 15, 260), and in the solution formed when conc. H.PtCl,Aq is added to hot conc. K.PtCl,Aq (Thomsen, J. pr. [2] 15, 294). When these liquids are evaporated in vacuo. a residue is obtained agreeing in composition with the formula HPtCl₃.2H₂O (= HCl.PtCl₃.2H₂O = H₂PtCl₂(OH).H₂O); at 100° this loses H₂O and HCl and leaves PtCl₂ (Nilson, *l.c.*).

Platino-chlorides M' PtCl, (Chloroplatinites). These salts are obtained by evaporating metallic chlorides with PtCl.Aq, or in many cases by reducing platini-chlorides. Most of the platinochlorides are very soluble in water, and crystallise only from very conc. solutions, generally forming dark-red crystals. Many of them are described by Nilson (J. pr. [2] 15, 260). Thomsen (Th. 8, 480) gives $[Pt,O]^2,2MClAq] = 41,830$; and [Pt,O,4MClAq] = 81,550; where M=H, K, Na, Am, Ba, Ca, Sr, or Mg.

Ammonium PLATINO-CHLORIDE Am.PtCl. (Ammonium chloroplatinite). Obtained, in four-sided prisms, by adding AmCl to PtCl, in HClAq, and evaporating; also by reducing hot Am2PtClaAq by SO2, or hot H2PtClaAq by SO2 and then adding AmCl (Peyrone, A. 55, 205; Thomsen, B. 2, 668; Grimm, A. 99, 95). $[Pt, Cl^2, 2AmCl] = 43,550$ (Th. 3, 430).

POTASSIUM PLATINO-CHLORIDE K.PtCl. (Potassium chloroplatinite). Large, ruby-red, foursided prisms; S.G. 3.2909 at 21°; easily sol. water, insol. alcohol (Nilson). An aqueous solution is not ppd. by soda or potash when cold; on boiling, all the Pt is thrown down as Pt(OH), (Thomsen, J. pr. [2] 15, 295). [Pt,Cl²,2KCl] - 45,170 (Th. 3, 430). Obtained by adding KCl to PtCl, in HClAq, and evaporating (Magnus, P. 14, 241); also by reducing K,PtCl,Aq by H.S. (Böttger, J. pr. 91, 251), or better by Cu₂Cl₂ (Thomsen, J. pr. [2] 15, 294). K₂PtCl₅ is made into a paste with water, warmed, and moist Cu₂Cl₂ is added, little by little, until a small excess is present; the liquid, which is nearly black, is filtered, the red crystals which separate on cooling are washed with alcohol and re-crystallised.

The following platino-chlorides have been isolated and described: Ba, with 3aq; Be, with 5aq; Ca, with 8aq; Cs (Böttger, J. pr. 91, 251);
Co, with 6aq; Cu, with 6aq (Thomsen, l.c.;
Millon a. Commaille, C. R. 57, 822); Fe^{cus}, with 6aq; Pb; Li, with 6aq; Mg, with 6aq; Mn, with 6aq; Ni, with 6aq; Rb; Ag; Na, with 4aq; Sr, with 6aq; Tl; Zn, with 6aq (Hünefeld, S. 60, 197).
Compounds of PtCl₂ with the chlorides of the following metals are also described by Nilson (l.c.); Al, Ce, Cr, Di, Er, La, Th, and Y.

Platino-chloronitrites; v. Platino-nitrites,

Platino-chlorophosphates (Phospho-platinochlorides). Several salts, and a few acids, containing Pt, Cl, and P have been isolated by Schützenberger (Bl. [2] 17, 482; 18, 101, 148). The classification of these compounds is very incomplete. The following scheme is accepted as provisional (cf. Seubert, Ladenburg's Hand-worterbuch der Chemie, 9, 314):

Platino-chlorophosphoric acid Cl.Pt:P(OH), by dissolving Cl.Pt.PCl, in water and crystal-

lising; (Cl.Pt:PO,),Pb,8aq, and various esters. isolated.

Platino-chlorodiphosphoric acid

P(OH) ; by the action of moist air on

Cl_Pt:| ; by the action of moist P(OH), Cl_Pt:Pcl_Pcl_; ethyl ester also isolated.

Platinochloropyrophosphoric acid

ClPt: d ; by warming a solution of

P(OH), Cl₂Pt:PCl₃.PCl₃.

Platino-chloro-anhydropyrophosphoric acid P(OH),

ClPt: Ò ; by heating the foregoing acid to P(OH)

150°. Ethyl diplatino-chloro-phosphate

Cl.Pt P(OEt), by dissolving Cl.Pt PCl, in alcohol; corresponding acid not isolated (Cochin. C. R. 86, 1402).

Platino-cyanides and derivatives : v. vol. ii. p. 344.

Platino-iodhydric acid H.PtI. (Iodoplatinous acid). This acid probably exists in a solution of PtL, in HIAq.

Platino-iodonitrites; v. Platino-nitrites.

Platino-nitrites, and derivatives. Platinous nitrite [Pt(NO2)2] has not been isolated; but several compounds are known in which the group Pt(NO₂)₂ forms part of the acidic radicle. These platino-nitrites belong to the form M2Pt(NO2); they are not to be regarded as double salts, but as derivatives of the acid H2Pt(NO2)4; the ordinary reagents for Pt do not show the presence of this metal in solutions of these salts, nor do these solutions give the reactions of nitrites; their solutions doubtless contain the ions M and Pt(NO2)4. Most of the platino-nitrites are obtained from the potassium salt K2Pt(NO2)4, which is formed by the reaction of equivalent weights

is formed by the reaction of equivalent weights of K_PtGl₄ and KNO₂.

PLATINO-NITROUS ACID H_Pt(NO₂)₄ has not been obtained pure, but it doubtless exists in the solution obtained by decomposing BaPt(NO₂)₄ by H_SO₄Aq; on evaporation, this solution gives red crystals (Lang, J. pr. 83, 415), but the process causes merical decomposition to but the process causes partial decomposition to triplatino-octonitrous acid H.Pt.O(NO2).2H20 (Nilson, B. 10, 934).

POTABSIUM PLATINO-NITRITE (Potassium nitroplatinite). Small, lustrous, colourless, monoclinic prisms; by mixing solu-tions of equivalent weights of K.PtCl, and KNO. and evaporating (Topsöe, J. 1879, 307). S. 3.8 at 15°; more sol. hot water. Combines with Br and Cl to form potassium platini-dibromo-[dichloro-] nitrites, K.PtBr. [Cl.] (NO.). Most of the other platino-nitrites are obtained from this salt, by adding AgNO,Aq, separating Ag,Pt(NO₂), and decomposing this by metallic ollorides; or making BaPt(NO₂), by the action of BaCl_Aq on the silver salt, and decomposing this by sulphates (Nilson, B. 9, 1722; 10, 980; 11, 879; v. also Blomstrand, J. pr. [2] 8, 186).

The other platino-nitrites which have been

isolated are: Al, Am, Cd, Ce, Cr, Co, Di, Sr, Fe, La, Pb, Li, Mg, Mn, Hg, Ni, Ag, Na, Tl, Y, and

PLATINO-BROMONITRITES M¹₂Pt(NO₂)_{4-x}Br_x.

A few of these salts have been obtained by Vezes (C. R. 113, 696; 115, 44). Potassium platino-bromonitrite K₂PtBr(NO₂)₂ and dibromo-nitrite K₂PtBr₂(NO₂)₂ are described.

PLATINO-CHLOROMITRITES M'_Pt(NO_1)_-_cCl_z. Vèzes (l.c.) has described the potassium monochloro-salt K_PtCl(NO_1),, and the dichloro-salt

K2PtCl2(NO2)2.

PLATINO-IODO-NITRITES M.Pt(NO₂)₄., I₂ (Nilson, B. 10, 930; 11, 879; Groth, Z. K. 4, 409; Vèzes, C. R. 115, 44). Potassium platino-di-iodo-nitrite K.PtI₂(NO₂)₂.Pl₂O is obtained, in small, black crystals, by the action of an alcoholic solution of I on K.Pt(NO₂)₄. The other salts isolated are those of Al, Am, Ba, Be, Cd, Cs, Ca, Ce, Co, Cu, Di, Fe, La, Pb, Li, Mg, Mn, Ni, Rb, Ag, Na, Sr, Tl, Y, and Zn.

Platino-nitrobromides; v. PLATINO-BROMO-

MITRITES, supra.

Platino-nitrochlorides; v. Platino-chloro-MITRITES. supra.

Platino-nitro-iodides; v. Platino-iodo-

NITRITES, supra.

Platino-oxalic acid and platino-oxalates $\mathbf{H}_{2}\mathrm{Pt}(\mathbf{C}_{2}\mathbf{O}_{4})_{2}$ and $\mathbf{M}^{1}_{2}\mathrm{Pt}(\mathbf{C}_{2}\mathbf{O}_{4})_{2}$ (Söderbaum, Bl. [2] 45. 188). The sodium salt Na,Pt(C,O₄),.4H₂O 45, 188). is obtained, in copper-coloured crystals, by he obtained, in copie-coloured trystalised oxalio acid, cooling the blue-coloured liquid, treating the brown needles which separate with hot water, and crystallising; sometimes the salt separates with 5H.O as golden-coloured crystals. The other salts are obtained by double decomposition from the Na salt; they seem to exist in two forms corresponding with the two sodium safts. Platino-oxalic acid H.Pt(C,O,),2H,O is obtained as red, lustrous, metal-like crystals by decomposing the silver salt with the equivalent weight of HClAq, filtering, and concentrating the blue solution in vacuo. Salts of the following metals are described by Söderbaum (l.c.): Am, Ba, Ca, Mg, Mn, Ni, K, Ag, Na, Sr, and Zn.

Platino-phosphochlorides v. Platino-chloro-

РИОЅРНАТЕS, р. 284.

Platino-seleno-stannates. Schneider (J. pr. [2] 44,507) has described two salts, K_Pt_SnSe, and Na_Pt_SnSe, which may be called platino-seleno-stannates. They are formed by heating together Pt black, SnSe, K_CO, or Na_CO, and Se.

Platine-stannates. This name may be given to some compounds derived from the acids H_Pt_Sn_O, and H_Pt_Sn_O, described by Schneider (P. 136, 105) and Schützenberger (C. R. 98, 985); cf. also Lévy a. Bourgeois (C. R. 94, 1365).

Platino-sulphocyanhydric acid, and salts v.

vol. ii. p. 857.

Platine-sulphonates, and derivatives (Liebig, A. 28, 23; Litton a. Schnedermann, A. 42, 316; Birnbaum, A. 189, 164; 162, 137; 159, 116; Dobereiner, J. pr. 15, 315; Lang, J. pr. 88, 415). (Platino-sulphites. Sulpho-platinites.) When K.PtCl., is heated with KHSO.Aq, or SQ, is passed into K.SO.Aq holding Pt(OH), in suspension, the liquid is neutralised by K.CO., and

evaporated, yellow, microscopic crystals are obtained of K_Pt(KSO_J),2H_Q. From this potassium platino-sulphonate other similar salts are obtained. These salts are better regarded as derived from platino-sulphonic acid H_Pt(HSO_J), than as double compounds of PtSO_a and K_SO_k(K_Pt(KSO_J)_i=PtSO_a,8K_SO_J]; they are analogous to the platino-chlorides M_PtCl, and the platino-nitrites M_Pt(NO_J). The ammonium, sodium, and silver salts have been isolated. Sodium-platino-oxy-sulphonic acid Na_Pt(HSO_J)_Q have also been isolated.

PLATINO - CHLOROSULPHONATES (Platino-chlorosulphites. Sulpho - chloroplatinites). Mt_Pt.Cl_1.M'SO_1. The potassium salt K_Pt.Cl_2.MSO_1 is obtained by warming K_PtCl_4 with SO_4Aq, evaporating, and adding KCl. Ammonium platino - chlorosulphonic acid Am_Pt.Cl_1.HSO_3 crystallises from a solution of Ant_Pt.Cl_3. To Am_Pt.Cl_4, in warm cone. SO_2Aq; the potassium and sodium salts of this acid are known. A complex acid, AmH.Pt.Cl.SO_*HSO_1 and the salts AmK.Pt.Cl.SO_*KSO_3 and Am_Pt.Cl.SO_*SO_3Am have been isolated.

Platino-thiosulphates. A few salts have been obtained which may be regarded as compounds of hypothetical platinous thiosulphate and sodium thiosulphate PtS₂O₃xNa₂S₂O₃.4/H₂O, where x is 3, 4, 6, and 7. They may also be looked on as derivatives of the hypothetical acid H₂Pt(S₂O₃H)₂, where H is replaced by Na (Schottländer, A. 140, 200; Jochum, C. C. 1886. 642).

M. M. P. M.

642).
PLATINUM. Pt. At. w. 194 8. Mol. w. unknown. Melts at c. 1775° (Violle, C. R. 89, 702); older determinations generally gave m.p. c. 2000° (for references v. Carnelley's Melting and Boiling Point Tables, p. 10), although Becquerel (C. R. 57, 855) gave 1460°-1480°. S.G. 2148 Och 1. 51, 630) gave 1300 1300 1300 1300 1500 150 at 17.6°, after melting in H (Deville a. Debray, C. R. 81, 839; for other values v. Clarke's Specific Gravity Tables, 2nd edit. p. 15). S.H. -03243 (Regnault); -0314 (Dulong a. Petit); -0317 + 000012t at to (Violle, P. M. [5] 4, 818). C.E. (linear at 40°) .00000899 (Fizeau, C. R. 68, 1125, for Pt that had been melted); from 0° to 100°, 00000881 (Calvert a. Johnson, B. A. 1858. for hammered Pt). T.C. (Ag = 1000) 379 (C. a. I.c.); c. 84 (Wiedemann a. Franz, J. 1855. 91). Heat of fusion c. 5276 (for 194 g.) (Violle, *Lc.*). E.C. (Ag = 100) 8.042 at 12°-18° (Becquerel, A. Ch. [3] 17,242); 10.53 at 20.7° (Matthiessen, P. 103, 428). For electrical resistance of Pt wire v. Arndtsen (P. 104, 1). Crystallines in the regular system (v. infra, Properties). For chief lines in emission-spectrum v. B. A. 1884. 436.

Occurrence.—Alloyed with Ir, Pd, Rh, Au, Cu, and Fe in the sands of many rivers, often associated with titaniferous iron and chromeiron, and in the older rocks in different parts of the world. The quantity of Pt in 'platinum ores,' varies from c. 50 to c. 90 p.c. A Canadian Ni ore was found by Clarke a. Catlett to contain from 008 to '02 p.c. Pt (Am. S. 37, 572). In 1741 Watson received some particles of a metallike substance from the gold-bearing sand of the river Pinto in New Granada; the shining silvery particles were called in the district where they occurred platina del Pisto [platina = diminuitye]

of Spanish plata = silver). Watson extracted a new metal from the substance sent him, and called it platinum (T. 1750. 585). For a short account of the history of the Pt metals, v. Noble metals, iv. 628.

Formation.-1. By decomposition of PtCl, or (NH₄).PtCl₄ by heat.—2. By heating an alloy of Pt and Pb in a current of air, whereby the Pb is oxidised and the Pt remains .- 3. By reducing many Pt salts by Zn, Fe, NaOHAq and FeSO, Aq, Na, CO, Aq and sugar, alcohol added to

an alkaline solution, &c.

Preparation.—1. The Pt ore is obtained as a fine powder by fusing with 2 or 3 times its weight of Zn, powdering the brittle alloy so formed, and removing the Zn by dilute H.SO.Aq (Descotils, G. A. 27, 231; Hess, J. pr. 40, 498). The residue is heated to redness, then warmed with HClAq (to remove portions of the baser metals), and then treated with cold aqua regia which dissolves Au. The residue is heated, in retorts, with aqua regia; the solution contains most of the Pt, along with Rh, Pd, and a little Ir; in the residue are found osm-iridium (v. vol. iii. p. 47), Ru, and a little Pt. The acid is distilled off, carrying with it most of the Os as OBO4; the concentrated solution is neutralised OSO; the concentrated solution is neutralised by Na,CO,, and the Pd is ppd. as PdCy, by HgCy,; NH,Cl is added to the filtrate, and (NH,),PtCl, is thus ppd. mixed with some (NH,),ItCl,. The Ir salt may be removed by digesting with slightly warm KCNAq until the undissolved portion is light yellow; the salt IrCl., 3NH, Cl is thus formed and dissolved, while (NH₄)₂PtCl₆ remains (Wöhler a. Mucklé, A. 104, 368). Or the NH₄.Pt and NH₄.Ir chlorides may be dissolved in hot water, and the Ir salt reduced to IrCl₂.3NH₄Cl, which dissolves, by SO₂ (cf. Iridium, vol. iii. p. 46). The residual ammonium platinichloride is then heated until all NH, and Cl are volatilised.—2. Finely-divided Pt ore is dissolved in aqua regia diluted with 2 pts. water, under increased pressure (which aids the solution); the solution is evaporated, and the residue is heated to 125°, whereby the chlorides of Pd and Ir are reduced to the lower chlorides; treatment with HClAq dissolves PtCl, which is ppd. as (NH,),PtCl, by addition of NH Cl (Heraus, v. Hotmann's Chem. Industrie auf der Wiener Weltausstellung, 2, 999; v. also Dullo, J. pr. 78, 869) .- 8. Commercial Pt is melted with 6 times its weight of Pb, the granulated alloy is treated with dilute HNO₃Aq (1:8 by volume), which dissolves most of the Pb, Cu, Pd, and Rh; the black residue is dissolved in diluted aqua regia-Ir remains undissolved—the solution is evaperated with H2SO, Aq, whereby Pb is removed as PbSO, the filtrate and washings are mixed with excess of NH,Cl and some NaCl, heated to 80°, and allowed to stand for some days; the pp. is washed repeatedly with saturated NH.ClAq, and then with very dilute HClAq; it is then dried, heated to dull redness in a Pt vessel with KHSO, and a little NH, HSO, and washed with boiling water -Rh goes into solution as Rh-K disulphate, and finely-divided Pt remains (Matthey, Pr. 28, 463). For other methods v. Deville a. Debray, A. Ch. [3] 56, 885; 61, 5.—4. Pure Pt is obtained by evaporating a solution of the ore in aqua regia with HClAq till HNO, is nearly removed, adding NaOHAq till strongly

alkaline, boiling for a long time (the alkalinity gradually disappears, owing to formation of NaClOAq), adding alcohol, and then making the turbid liquid acid by HClAq, filtering from olivegreen IrCl,, and ppg. by conc. NH, ClAq (W. von Schneider, A. Suppl. 5, 261). The Pt obtained by strongly heating the ppd. (NH₄)₂PtCl₆ should. be dissolved in diluted aqua regia, and re-ppd. by addition of NH₁Cl; on heating this pp. pure Pt remains (Seubert, A. 207, 8). For another method of obtaining pure Pt, v. Mylius a. Förster, B. 25, 665.

The finely-divided Pt obtained by the above methods may be fused into a lump by the use of the O-H flame. The metal is placed in a cavity made in a block of lime (made by strongly heating marble), which is covered by another block, through the top of which a hole is pierced to admit the flame (v. Deville a. Debray, A. Ch. [3] 56, 385; cf. PLATINUM in DICTIONARY OF APPLIED

CHEMISTRY).

Platinum black, which is extremely finelydivided Pt, is obtained by reducing solutions of some Pt salts by certain organic reducing compounds, or by Zn or Mg, &c. PtCl, Aq may be reduced by Mg (Böttger, J. pr. [2] 2, 137), zincedust or Fe in powder (Brunner, A. 109, 253), FcSO, Aq and NaOHAq (Hempel, A. 107, 97), sugar and Na₂CO₃Aq, or by alcohol. Pt black is also formed by fusing Pt with twice its weight of Zn, powdering the alloy, dissolving out Zn by H.SO, Aq, and washing with very dilute HNO, Aq (Döbereiner, A. 17, 67). Loew (B. 23, 289) recommends to dissolve 50 g. PtCl₄ in 50-60 c.c. water, to add c. 70 c.c. formic aldehyde solution of 40 to 45 p.c., to cool, and then to add gradually 50 g. NaOH in 50 c.c. water, to set aside for 12 hours, and then to filter and wash until the washings pass through black, when the washing should be stopped for some hours, and continued when the washings again pass through colourless (O is absorbed and temperature rises); the residue is washed until quite free from NaCl, and dried over H2SO4. Liebig (P. 17, 101) dissolved PtCl2 in warm conc. KOHAq, added alcohol to the hot liquid till CO, came off freely, decanted, washed the ppd. Pt, successively, with alcohol, HClAq. KOHAq, and finally, several times, with boiling water.

Crystals of platinum are obtained by heating Pt to redness, in a glass or porcelain tube, in a stream of dry Cl, for twenty-four hours (Hodgkinson a. Lowndes, C. N. 58, 158, 203; Seelheim, B. 12, 2066; Joly, N. 43, 541; cf. Troost a. Hautefeuille, C. R. 84, 94). Joly (N. 43, 541) obtained cubical crystals of Pt, about 1 mm. in length, by sprinkling some finelypowdered topaz on a ribbon of Pt, and heating to bright redness by an electric current for c. two hours. Moissan (C. R. 109, 807) obtained crystalline Pt by heating dry PtF, in a Pt tube, to bright redness. Pt that has been melted shows a crystalline structure when touched with aqua regia (cf. Koettig, J. pr. 71, 190; Nogoks, C. R. 47, 832; Kalischer, B. 15, 706; Mallet, Am. S. [2] 20, 340; Phipson, C. N. 5, 144).

Treatment of platinum residues.—Pt residues accumulated in the laboratory generally contain Pt as (NH₁)₂PtCl₂; the liquid portion usually contains alcohol. The solid part is warmed, in a water-bath, with K₂CO₂Aq, KOHAq,

er NaOHAq, and the alcoholic liquid is added little by little, or HCO₂Na is added (Duvillier, C. R. 84, 444), till the salt is reduced to Pt. The black residue is washed, dried, boiled with HClAq, and again washed and dried (Knösel, B. 6, 1159).

Properties.—Compact platinum is a white metal with a greyish tinge; it is easily polished, thereby acquiring a very high lustre. Much softer than Ag, rather softer than Cu: thin plates or wire can be cut easily with scissors. Without taste or smell. Very malleable and ductile; a wire 2 mm. diameter breaks with a weight of 124 kilos; tenacity is, therefore, c. same as Fe. Pure Pt can be drawn into very thin wire; by fusing into Ag wire, drawing out, and dissolving away the Ag, a wire of Pt 0009 mm. diameter is said to have been obtained (Gaiffe, C. R. 1877. 625). Most easily fused of Pt metals except Pd; very thin wire melts in the outer blow-pipe flame; larger masses require the O-H flame. Becomes soft and workable much below its m.p. Melts in an ordinary fire, owing to combination with C or Si (Heraeus, D. P. J. 167, 132; Deville, A. Ch. [3] 46,182; Boussingault, C. R. 82,591; Schützenberger a. Colson, C. R. 94, 1710). Crystallises in the regular system, chiefly in octahedral and dodecahedral forms (v. Scelheim, B. 12, 2066). Said to volatilise to some considerable extent when kept molten (Deville a. Debray, C. R. 44, 1101). By heating in certain gases, especially in Cl, volatile compounds are formed and again decomposed. Molten Pt absorbs O, and 'spits' when cooled rapidly.

Pt occludes H. According to Graham (P. M. [4] 36, 63), Pt foil absorbs five to six times its own volume of H at a dull-red heat; Berthelot (C. R. 94, 1383) says that Pt absorbs from 80 to 120 times its volume of H, probably with formation of definite compounds. Berliner (W. 35, 791; cf. Neumann, M. 13, 40) found that ordinary Pt foil absorbed 127 volumes of H; foil that had been quite freed from gases and cleaned absorbed 200 vols. of H and 80 vols. of O or CO. The whole of the occluded gas is removed, with difficulty, by strongly heating in vacuo; under ordinary conditions about 80 vols. of H are retained. O is also occluded by Pt foil, and the condensed O brings about oxidations, e.g. electrolytic gas (H₂+0) explodes when exposed to Pt foil at c. 180° (Berliner, l.c.). Pt is pervious to H at a bright-red heat; Graham (P. M. [4] 32, 401, 503) found that 489-2 c.c. H passed, per minute, through Pt foil 1-1 mm. thick and having a surface of 1 square metre. Gases other than H scarcely diffused through at all.

Pt is not acted on by pure HClAq, HNO,Aq, or H,SO,Aq, nor is it attacked by O; various mixtures of acids dissolve it. Pt is acted on by Cl and by substances which evolve Cl; also, at high temperatures, by molten alkalis, nitrates, KCN, a mixture of alkali carbonates with S, by P and Si, and by most of the metals.

Platinum black is a porous, heavy, very finely-divided black powder, which becomes metal-like, grey, and lustrous when rubbed; S.G. 15-8 to 17-6. Pt black absorbs large quantities of certain gases, especially 0; according to Döbereiner (A. 17, 67), from 173 to 253 vols.

O are occluded by 1 vol. Pt black. The O condensed in Pt black is able to bring about many processes of rapid oxidation: H, CO, C.H., C.H., O gas, Et.O vapour, &c., are rapidly oxidised, generally with ignition (v. von Mulder, R. T. C. 2, 44; Schönbein, J. pr. 98, 76; P. 105, 258; von Mulder a. van der Meulen; R. T. C. 1, 167); alcohol is oxidised to acetic acid, formic and oxalic acids to CO, and H.O, As.O. to As.O. (von Mulder, R. T. C. 2, 44). Pt black charged with H acts as a reducer; water is formed when the hydrogenised Pt black is brought into O (Wilm, B. 14, 878; Berthelot, C. R. 94, 1377); aqueous solutions of KClO₃, KNO₃, K.FeCy, also C.H.NO₃, &c., are reduced (Gladstone a. Tribe, C. N. 37, 245); ozone is reduced to O (von M. a. van der M., Lc.). One cause of these actions is probably the heat produced during the condensation of the gases in the porous Pt (cf. Berthelot, A. Ch. [5] 30, 519); it is not probable that an oxide of Pt is formed and then reduced (D. V. Meyer, 1, pr. [2] 14, 124; cf. Tommasi, B. 11, 811).

of Pt is formed and then reduced (p. V. Meyer, J. pr. [2] 14, 124; cf. Tommasi, B. 11, 811).

The at. w. of Pt has been determined (1) by strongly heating PtCl. (Berzelius, P. 8, 179 [1813]); (2) by determining Pt in K. PtCl., and by finding the ratio of Pt:KCl in the same salt (B., P. 13, 469 [1826]; Andrews, Chem. Gazette, 1852, 379); (3) by analyses of K,PtCl, and (NII,),PtCl, (Scubert, A. 207, 29 [1800]; Halberstadt, B. 17, 2962 [1884]; cf. Dittmar a. McArthur, E. Tr. 33, 561 [1888], and criticism thereon by Scubert, B. 21, 2179; (4) by determining S.H. of solid Pt (Violle, P. M. [5] 4, 318). As no V.D. of a Pt compound has yet been determined, the at. w. cannot be found by the direct application of the law of Avogadro. The older determinations gave 196 to 197; Seubert proved that the true value is c. 194.5, which is between the values for Ir (192.5) and Au (196.8). No compound of Pt has been gasified from which the valency of the atom of Pt in gaseous molecules can be determined. Pt is closely allied to Ir, and less closely to Os, in its chemical properties. It is distinctly metallic physically, and, on the whole, chemically also. PtO, is both basic and acidic; Pt forms numerous acids by combining with H and negative radicles such as Cl, (NO), Cl, (CN), (SCN), &c. For a fuller account of the chemical relations of Pt v. Noble metals, vol. iii. p. 628, and cf. Iron GROUP OF ELEMENTS, vol. iii. p. 67.

Ptis used for making crucibles &c. for laboratory use, and vessels for evaporating cone. oil of vitriol, &c. Apparatus is sometimes platinised by placing in hot PtCl,Aq containing KOH and some organic reducing compound.

Reactions and Combinations.—1. Is not acted on by oxygen; concerning absorption of O by Pt v. Properties.—2. Heated to redness with sulphur, in presence of borax, PtB is formed (Deville a. Debray, C. R. 89, 587).—5. Said to form a compound by leating Pt black with selenion.—4. With chlorine, bromine, and iodine Pt reacts at temperatures above c. 300° (Langer a. Meyer, Pyrochemische Untersuchungen (Braunschweig, 1885) 44, 57). Cl and Br attack Pt in presence of water.—5. Scarcely acted on by fluorine below 100° (Moissan, A. Ch. 1892, 125), 6. Hydrogen is occluded by Pt; a considerable quantity of heat is produced, and perhaps compounds are formed (v. Platinum Etdalde, p.

290).-7. Heated with arsenic, a compound! PtAs, is said to be formed (v. Gm.-K. 3, 1192-1198).—8. Phosphorus combines when heated with finely-divided Pt (Schrötter, J. 1849. 246). 9. A boride is formed by heating Pt black with amorphous boron (Descotils, A. Ch. [3] 67, 88; Deville a. Wöhler, J. 1856. 279).—10. Heated to whiteness with silicon, Pt forms several compounds; also combines with Si when heated with silica and carbon (v. PLATINUM SILICIDES, p. 291).-11. Softens when heated with carbon v. PLATINUM CARBIDE, p. 289) .- 12. Alloys with many of the more casily fusible metals (v. PLATINUM ALLOYS, infra).—13. Pt is not acted on by pure hydrochloric, nitric, or sulphuric acid (Scheurer-Kestner, C. R. 86, 1082; 91, 59). It dissolves in warm aqua regia, forming PtCl. (v. Dullo, J. pr. 78, 369). Alloying modifies the solubility in acids; alloys of Pt with small quantities of Ir or Rh are scarcely with small quantities of it of An all scales, sol. in aqua regia, while an alloy with much Ag dissolves in cone. HNO₃Aq; Pt ppd. by zane dissolves in cone, HNO₄Aq (v. Winkler, Fr. 13, 869; van Riemsdyk, B. 16, 387; Wilm, B. 13, 1198) .- 14. Conc. sulphuric acid containing a little nitrous acid dissolves small quantities of Pt (Scheurer-Kestner, C. R. 86, 1082; 91, 59). Nitric acid, containing bromine or bromhydric acid, and also hydrochloric acid, into which chlorine is passed, dissolve Pt, forming PtBr, and PtCl, respectively (Wagner, W. J. 1876. 149; Seubert, A. 207, 16).—15. Pt is acted on, at red heat, by molten alkalis, baryta, nitrates, potassium cyanide, and by a mixture of alkali carbonate and sulphur .- 16. PtCl, or PtBr, and PtI2 are formed when Pt wire is heated in iodine mono- or tri- chloride, or in chlorine mixed with iodine or iodine bromide; with phosphorus pentachloride Pt phosphide is formed; with carbon tetrachloride C, C,Cl, and Cl are produced; hydrogen chloride forms PtCl2; hydrogen fluoride produces a soluble Pt salt; and with mercurous chloride Hg and PtCl, are obtained (Hodgkinson a. Lowndes, C. N. 58, 223).

Platinum, acids of. The hydroxide Pt(OH), reacts with strong bases as an acid. Several acids have been isolated containing Pt in acids have been isolated containing Pt in combination with more or less complex negative radicles; these are II_PtCl,, H_PtCl,, H_PtBr,, H_PtL,; H_Pt(NO.),, H_Pt_iO(NO.),; H_Pt_iS, Pt(NH_), Cl.SO_H; PtCl_P(OH),. These acids are described as platino- and platini-chlorhydric acid to (IP_S) 93 and 393) victims viteward. acid, &c. (pp. 283 and 282); platino-nitrous acid, co. (p. 284); platino-cyanhydric acid, co. (vol. ii. pp. 344-5); thioplatinic acid (p. 281); platos-ammine-chloro-sulphonic acid (p. 293); platino-

chloro-phosphoric acid (p. 281).

Platinum, alloys of. Pt alloys with many metals by fusing it with them; with Sb, As, Pb, Sn, and Zn heat and light are produced. Alloys which seem to be definite compounds have been obtained with arsenic (PtAs., Gehlen, Gm.-K. 8, 1192); antimony (PtSb., Christofle); cadmium (PtCd., Deville a. Debray, A. Ch. [3] 56, 886); kad (PtPh, Bauer, B. 3, 836; 4, 449; D. a. D., C. R. 90, 1195); tin (PtSn., PtSn., and Pt.Sn., D. a. D., A. Ch. [8] 56, 885; Debray, C. R. 104, 1470); and zinc (Pt.Zn., D. a. D., l.c.). Alloys have also been formed with bismuth (Gehlen, Gm.-K. 3, 1192); copper (D. a. D., A. Ch.

1859. 611; Hélonis, B. 6, 42); gold (Dodé, B. 6, 1273); iridium (D. a. D., A. Ch. [3] 56, 385; Pelouze, C. R. 49, 896; Matthey, Pr. 28, 463; D. a. D., C. R. 81, 839; Morin, C. R. 78, 1502); iron (D. a. D., C. R. 89, 587; Daubrée, C. R. 80, 520); nickel (Hélonis, B. 6, 42); potassium (V. Meyer, B. 13, 892); silver (D. a. D., A. Ch. 1859, 611; H., l.c.); sodium (V. M., l.c.)

Analgams of platinum. According to Crafts (Bl. [2] 49, 856), Hg has no action on Pt at the ordinary temperature, but Pt dissolves to a very small extent in boiling Hg, air being excluded. When acid is present Hg alloys with Pt (Casamajor, Am. 6, 540; Skey, C. N. 22, 282; Krouchkoll, J. de Ph. [3] 3, 139). The amalgams are most easily formed by adding sodium-amalgam to PtCl, Aq; with 13.5 p.c. Pt the amalgam is a thick liquid; with 25.8 p.c. Pt it is solid; an amalgam with c. 30 p.c. Pt has also been ob-

tained (Joule, C. J. [2] 1, 378).

Platinum, antimonide of. An alloy of Pt and Sb, approximating to the composition PtSb, is obtained by melting the elements together in the ratio Pt: 2Sb; also by passing SbH, into II_PtCl,Aq, and removing ppd. Sb and PtCl, by washing with K,SAq and KCNAq mixed (Christofle, Recherches sur les Combin. de l'Antimoine.

Göttingen, 1863).

Platinum, arsenides of. An alloy PtAs, is said to be formed by heating Pt black with As (Gehlen, Gm.-K. 3, 1192). By passing AsH₄ into PtCl₄Aq, and heating the pp. in dry CO₂, Pt₄As₂ is said to be formed (Tivoli, G. 1885.

Platinum-arsenic hydroxide. According to Tivoli (G. 1885, 487) a compound PtAsOH is produced by passing AsII, containing H but no other impurity, into PtClAq (corresponding with 2 g. Pt in 60 c.c. water), and drying the black floculent pp. at 120°-130°. The compound is decomposed by washing with alcohol or water; hot conc. H₂SO₄ at once separates Pt; heating in dry CO₂ produces As₂O₃, Pt₂As₂, and H₂O. Gibbs (Am. 8, 2*9) described some compounds of Pt and As.O.

Platinum, boride of. Pt and B combine when melted together (Descotils, A. Ch. [3] 67, 88). It is best to heat Pt black and amorphous B under borax (Wöhler a. Debray, A. 101, 113). When excess of B is used, a crystalline compound containing 91.8 p.c. Pt., S.G. 17.3, is formed

(Martius, A. 109, 79).

Platinum, bromides of. Pt and Br combine when heated together to above 300° (Langer a. Meyer, Pyrochemische Untersuchungen [Braunschweig, 1885], pp. 44, 57). Two bromides are known, PtBr₂ and PtBr₄; the V.D. of neither has been determined.

PLATINUM DIBROMIDE PtBr₂ (Platinous bromide.) Formed by heating HBrAq, b.p. 126°, with Br and spongy Pt to 180° in a sealed tube—H.PtBr. TH.O is thus formed—evaporating to dryness, heating to c. 200°, and washing the residue with boiling water (Topsoe, J. 1868. 273). Pullinger (C. J. 59, 602) heats spongy Pt with Br and HBrAq in a flask with a reflux-condenser, evaporates to dryness, and heats the residue to c. 280°. PtBr, is a brown powder; decomposes slowly at c. 800° in an air-current (P., l.c.); insol. water, sol. HBrAq and KBrAq. With KBr forms K_PtBr, (v. Platino-BBOMIDES,

Combines with CO at c. 180° to form p. 282). Combines with CO at c. 180° to form PtBr. CO, a bright red, crystalline solid; melts at 177.7°; not very hygroscopic; sol. alcohol; decomposed by water (Pullinger, l.c.). This compound is called by P. carbonyl-bromoplatinite.

PLATINUM TETRABROMIDE PtBr. (Platinic bromide). Formed by heating spongy Pt with Br and HBrAq in a sealed tube to 180°—or by boiling Br, Pt, and HBrAq in flask with 1eflux-condenser (Pullinger, C. J. 59, 602) filtering, evaporating, heating residue at 180° till HBr ceases to come off; treating with boiling water, filtering from traces of PtBr, evaporating, and drying at 180° (H. Meyer a. Züblin, B. 13, 404; Halberstadt, B. 17, 2963). A dark-brown, non-hygroscopic powder; sol. aqueous alcohol, more sol. absolute alcohol or ether, v. sl. sol. water (S. at $20^{\circ} = .41$) (H. l.c.); somewhat sol. glycerin. Pt black separates when solution in alcohol, ether, or glycerin is heated. With HBr forms H2PtBr, (v. PLATINI-BROMHYDRIC ACID, p. 282). With many metallic bromides forms salts M. PtBr. (v. Platini-bromides, p. 282). When spongy Pt is heated with HBrAq and excess of HNO3, small, dark-brown, very hygroscopic crystals of platinum nitrosyl bromide, PtBr, 2NOBr, are obtained (Topsoë, J. 1868.

273).

Platinum, carbide of. Pt becomes brittle and more friable when heated to redness with charcoal. By heating the compound which PtCl, forms with acetone, Zeise (J. pr. 20, 209) obtained a black solid, to which he gave the composition PtC,

Platinum, chlorides of. Two chlorides of Pt are known, PtCl₂ and PtCl₄. When Pt black is heated in dry Cl at 240 -250°, PtCl₄ is formed, according to Schützenberger (C. R. 70, 1134, 1287). Pigeon (C. R. 108, 1009) says that at 360° PtCl, and PtCl, are formed, but the action is incomplete. Troost a. Hautefeuille (C. R. 84, 94) found that PtCl, was formed when Pt was heated in Cl to 1400°, and the tube was suddenly cooled.

PLATINUM DICHLORIDE PtCl, (Platinous chloride. Platinochloride). V.D. not determined.

Formation. -1. By heating H.PtCl, to c. 230° (Berzelius, Gm.-K. 3, 1081). - 2. By heating Pt black in Cl at 240°-250° till no more Cl is taken up (Schützenberger, C. R. 70, 1134, 1287).—

8. By decomposing Na,Pt(NaSO₃), by HClAq (Liebig, A.23, 23; for formation of Na,Pt(NaSO₃), v. Platinosulphonates, p. 285) .- 4. A solution of PtCl. is obtained by passing SO, into PtCl, Aq till

the liquid becomes red.

Preparation. -1. H2PtCl8Aq is evaporated to dryness, and the residue is heated in a bath of molten tin, i.e. at c. 230°, with constant stirring as long as Cl is given off (Berzelius, Gm.-K. 3, 1081). Or the heating is stopped before much of the solid is decomposed, the residue is dissolved in water, the dark-brown opaque liquid is evaporated, and the PtCl, which separates is dried at c. 150° (cf. Magnus, P. 14, 239). 2. H.PtCl.6H.O is heated in vacuo, in presence of molten KOH, at 100° for 2 or 3 days; the temperature is then raised to 360°, and main-C. R. 112, 1218). Shenstone a. Beck (C. J. 61, 445) say that PtCl, prepared as directed above, Vol. IV.

always contains small quantities of some basic compound; and that when the salt is strongly heated small quantities of HCl and O are obtained, as well as Cl. Shenstone (C. J. Proc. 1892 93. 38) finds that PtCl. almost free from basic compounds can be prepared by heating PtCl₄ in a stream of dry HCl; a sample prepared in this way gave only 15 p.c. of HCl and O when

decomposed by heat.

Properties and Reactions .- A brown powder; S.G. 5.87 at 11° (Bödeker). H.F. [Pt,Cl*] = 22,600 (Berthelot, C. R. 87,615). Insol. water, sol. HClAq in absence of air. Decomposed by heating to redness, giving off all Cl, and leaving Pt. According to Shenstone a. Beck (v. Preparation), the Cl thus obtained contains a little HCl and O, and H₂O is also given off. Not acted on by HNO₂Aq or dilute II₂SO₄Aq; decomposed by KOHAq, giving Pt(OII)₂; by heating with conc. H.SO, and then with water, Kane obtained a black powder to which he gave the composition PtCl₂3PtO (B. J. 24, 238).

Combinations.—PtCl, combines with many metallic chlorides; the compounds are described as platino-chlorides (p. 284). With HCl an acid H2PtCl, is formed (v. Platino-chlorhydric acid, p. 283). With CO the compounds PtCl₂.CO, PtCl₋₂.2CO, and 2PtCl₋₃.3CO are formed. These compounds are produced by passing alternate currents of Cl and CO over spongy Pt at 250° (Schützenberger, A. Ch. [4] 21, 350). Pullinger (C. J. 59, 598) found that a fourth compound is also formed -PtCl₂.2COCl₂ (or PtCl₄.2CO), Carbonyl chloroplatinite (PtCl₂.CO) combines with HCl, and with various hydrochlorides of organic bases (v. Mylius a. Förster, B. 24, 2424). PtC1, combines with PCl, to form PtCl, PCl, and PtCl_2PCl_; and from these is derived a number of complex bodies. By treating PtCl, PCl, with H₂O an acid PtCl, P(OH), is ob-By treating tained, from which various salt-like compounds are derived; similarly PtCl2.2PCl3 yields an acid PtCl_P2(OH), and this gives many salt-like derivatives (Schützenberger, A. Ch. [4] 15, 100; 21, 350; Baudrimont, C. R. 53, 637: cf. PLATINO-GHIOROPHOSPHARES, P. 284). By heating PtCl, PCl, with PtCl, Colchin (O. R. 86, 1402) obtained 2PtCl, PCl, For ammoniacal derivations of the PtCl, Colchin (O. R. 86, 1402) tives of the platino-phosphorus chlorides v. Colchin (l.c.) and Quesneville (M.S. [3] 6, 659), also Schützenberger (Bl. [2] 14, 97; 17, 482; 18, 101, 148).

PLATINUM TETRACHLORIDE PtCl. (Platinic chloride. Platinichloride). V.D. not determined.

Formation.—1. By heating Pt in Cl to c. 1700° (Langer a. Meyer, l.c. 44, 57); if a thin wire of Pt is heated by an electric current nearly to melting, in a stream of Cl, PtCl, is formed (Hodgkinson a. Lowndes, C. N. 58, 158, 228).-2. By allowing H_PtCl_s.6H_O to remain over 2. By allowing H₂PtCl₂GH₂O to remain over KOH, when it loses 4H₂O, and then heating in Cl to c. 350° (Pigeon, C. R. 110, 77).—3. By heating Pt and Se, mixed with AsCl₃, in Cl (v. Preparation).—4. PtCl₂SH₂O is obtained by adding AgNO₂Aq to H₂PtCl₂Aq in the ratio of H₂PtCl₂(2AgNO₃, heating, filtering from AgCl₃ and evaporating finally over H₂SO₄ (Norton, J. pr. [2] 2, 469; 5, 365; Engel, Bl. [2] 50, 100; Quesneville, M. S. [8] 6, 659).

Preparation.—1. Support Pt is mixed with

Preparation.—1. Spongy Pt is mixed with rather less than its own weight of Se, the mix-

ture is placed in a tube of hard glass filled to one-third with AsCl, and heated in a stream of Cl till the mass liqueties and boils, when the tube is sealed and heated for some hours at 250°; on cooling, the colourless crystals are separated from the pale-yellow crystals and the yellow liquid, and are heated in vacuo at 110°, whereby PtCl, and SeCl, remain; this residuo is then heated at 360° in a stream of Cl, when SeCl, sublimes and PtCl, remains (Pigeon, C. R. 108, 1009). -- 2. Dry H,PtCl, is placed in a porcelain boat which is heated, in a tube of hard glass, to 165° for about 15 hours in a stream of dry HCl (Pullinger, C. J. 61, 422).

Properties and Reactions. - H.F. [Pt,Cl] = 59,800; [Pt,Cl',Aq] = 79,400 (Pigeon, C. R. 110, 77; 112, 791). A brown solid, said by Pigeon to be deliquescent; described by Pullinger as very soluble in water, but not deliquescent. The hydrate (v. Fornation, No. 4) forms large, red, monoclinic crystals; according to Norton this compound has 5H.O. according to Engel 4H,O ; all H.O except one molecule is removed at 100°, but the last molecule is not removable without decomposition. Decomposed by heating to dull redness (Pigeon, C. R. 110, 77); in presence of Cl, may be heated to c. 360°; in dry HCl slight decomposition occurs at c. 200° (Pullinger, Le.). HClAq produces H.PtCl., Aq; NH,Cl. ppts. (NH,).PtCl. AgNO, Aq ppts. Ag,PtCl., from cold PtCl, Aq, but on heating AgCl is formed and PtCl, goes into solution (Jörgensen, J. pr. [2] 16, 345). Piggon (C. R. 119, 761). 112, 791) gives [Ag²PtCl⁴,Aq] = 12,160, to form PtCl,Aq and 2AgCl; PtCl,Aq is decomposed by light, for some measurements v. Fousscreau (C. R. 103, 248).

Combinations .- 1. With water (v. Formation. No. 4, and Properties). — 2. With hydrogen chloride to form H.PtCl_v-6H.O; the compound HPtCl, 2H, O was obtained by Pigeon by heating H.PtCl. 6H,O in vacuo at 100° (v. PLATINIоньовнурко асто, р. 282). Pigeon (С. R. 110, 77) gives [PtCl⁴,2HClAq] = 24,800. — 3. With many metallic chlorides to form platini-chlorides (q. v., p. 282).—4. A compound with phosphorous chloride PtCl, PCl, is formed by treating PtCl, PCl, with Cl (Schützenberger, Bl. [2] 14, 97; 17, 482; 18, 101, 148; cf. Baudrimont, C. R. 53, 637) .- 5. A compound with nitrosyl chloride, PtCl, 2NOCl.H.O, is one of the products of the action of fuming HNO, on the products of the action of luming fino, on H.PtCl₂Aq (Weber, P. 131, 441).—6. Combines with alcohol, and with ethyl sulphide, to form PtCl₂.2C₂H₂O and PtCl₂.2(Et)₂S respectively (Sohützenberger, C. R. 70, 1134; Blomstrand, J. pr. [2] 17, 189).—7. Compounds with various organic bases and metallic chlorides, EtNH, &c., are described by Jörgensen (J. pr. [2] 33,

409).
Platinum, chloro-iodides of; v. Platinum IODOCHLORIDES, infra.

Platinum, cyanides of: and derivatives: v. vol. ii. p. 343.

Platinum, fluoride of. Only one fluoride of Pt has been isolated, PtF. Prepared by heating Pt wire in F, in a Pt or fluorspar tube, to c. 500°; if HF is mixed with the F combination occurs at the ordinary temperature (Moissan, C. R. 109, 807). Small buff-coloured crystals, or fused masses of a deep red colour. Dissolves in a little water, forming fawn-coloured solution, which almost at once decomposes, with rise of temperature and production of PtO, xH,O and HFAq. Heated to bright redness in Pt tube, PtF, is decomposed to F, and Pt which separated in crystals. A compound with PF, viz. PtF, 2PF, is formed by passing PF, over spongy Pt heated to dull redness (M., Bl. [3] 5, 454). The decomposing action of H.O on PtF, explains the failure of former attempts to prepare a fluoride of Pt in the wet way.

Platinum-iridium, or platin-iridium. An alloy of Pt and Ir which remains, mixed with osm-iridium, when many samples of Pt ore are heated with aqua regia (cf. IRIDIUM, vol. iii. p. 46).

Platinum, hydride of. Pt black absorbs considerable quantities of H. According to Berthelot (A. Ch. [5] 30, 519), the relative weights of Pt and H are approximately 15:1 and 10:1; a considerable quantity of heat is produced. No certain evidence of the formation of hydrides has been obtained; but Thoma's result (Z. P. C. 3, 69), that the excess of II, above a definite quantity, absorbed by Pt when Pt is the negative electrode during the electrolysis of dilute sulphuric acid, is not easily given up, indicates the probable existence of a compound or

compounds (cf. Palladium, vol. ii. p. 720).

Platinum, hydroxides of; v. Platinum,

OXIDES AND HYDROXIDES OF, p. 291.

Platinum, iodides of. Pt and I combine directly to form PtI,; the lower iodide PtI, has also been obtained, but not pure.

PLATINUM DI-IODIDE PtI, (Platinous iodide. Platino-iodide). This compound is described as a black, heavy powder, insol. water, alcohol, and acids; giving Pt and I at 300°-350°; decomposed by NaOHAq to PtO,H₂. It is produced by boiling PtCl₂ with fairly conc. KIAq (Lassaigne, A. Ch. [2] 51, 113); but it has not been obtained pure (Clementi, J. 1858, 420; Topsoë, Ar. Sc. 38, 297). The compound PtI. CO, carbonyl iodoplatinite, is described by Mylius a. Förster (B. 24, 2424).

PLATINUM TETRA-IODIDE PtI, (Platinic iodide. Platini-iodide). V.D. not determined. Prepared by heating PtO₂ with HIAq (Clementi, J. 1855. 420); also by the action of cold HIAq on H.PtCl₂.6H₂O (Topsoë, Ar. Sc. 38, 297), and evaporating. Pullinger (C. J. 59, 602) obtained PtI, by dissolving spongy Pt in a hot solution of I in HIAq, evaporating to dryness, heating to 180°, and washing with water. A brown-black amorphous powder, insol. water; sol. HIAq and metallic iodide solutions (Topsoë, l.c.); not wholly decomposed by heating with Na,CO, to the m.p. of the carbonate (Pullinger, l.c.). Combines with HI to form H2PtI8.9H2O (v. PLATINI-IODHYDRIG ACID, p. 283), and with metallic iodides to form salts (v. Platini-iodides, p. 283).

Platinum, iodochlorides of. A compound PtI₂Cl₂ is said to be formed, in large red plates, by dissolving Pt and I in aqua regia and evaporating at 100° (Kämmerer, A. 148, 329). Another compound PtI₂Cl was obtained by Mather, as a black powder, by evaporating H₂PtCl₂ with a small excess of HIAq, and heating the residue to 150° (Am. S. 27, 257).

Platinum-nitrosyl bromide and Platinum-

nitrosyl chloride, v. PLATINUM TETRABROMIDE.

p. 299; and Platinum Tetrachloride, Combinations, No. 5, p. 290.

Platinum, oxides and hydroxides of. Three oxides have been isolated; PtO, Pt₃O,, and PtO₂; hydrates of all are known. PtO forms a few salts; it also dissolves in molten KOH and NaOH. PtO₂ forms corresponding salts, and also combines with alkaline oxides to form platinates (q. v. p. 281).

PLATINUM MONOXIDE PtO (Platinous oxide). Obtained as a violet powder, by strongly heating the pp. formed by CaOAq acting on H2PtCl,Aq in sunlight, and washing with water and then with HNO₃Aq (Döbereiner, P. 28, 181). Also by carefully heating PtO2H2. Reduced to Pt at red heat, also by action of reducers such as Dissolves in molten KOH and HCO, HAq. NaOH, but the compounds thus formed have not been examined. A compound which is perhaps Pto.CO is described by Mylius a. Förster (B.

24, 2440). PLATINOUS HYDROXIDE Pto.H., was obtained by Thomsen (J. pr. [2] 15, 294) by adding NaOHAq to K_PkCl₄Aq (1:12) in the ratio 2NaOH:K_PkCl₄, and heating to boiling. A black powder, sol. HClAq, HBrAq, and SO2Aq, forming corresponding salts. Freshly ppd. Pto.H. dis-

solves in excess of NaOlIAq.

TRI-PLATINUM TETROXIDE Pt.O. (Platinoplatinic oxide). A black powder, insol. acids; obtained by heating dehydrated Na, PtCl, with 4 parts dry Na CO, till fusion begins, boiling with water, then with dilute HNO, Aq, and finally with aqua regia (Jörgensen, J. pr. [2] 16, 344). Loses its O at red heat; easily reduced to Pt by H or coal-gas, even without heating. Prost (Bl. [2] 46, 156) describes a hydrate Pt,O4.9H2O.

PLATINUM DIOXIDE PIO, (Platinic oxide). A black powder, obtained by gently, heating PtO, H., PtO, is insol. acids, but saits of this

oxide are formed from the hydroxide.

PLATINIC HYDROXIDE PtO, H,. Formed by boiling PtCl,Aq for a considerable time with a large excess of NaOHAq, acidifying by acetic acid, drying the white flocculent pp. in the air, and heating the yellow hydrate, PtO,H, 2H,O to 100° (Topsoë, B. 3, 462; Fremy, A. Ch. [3] 31, 478). Also obtained by evaporating H.PtCl.Aq with excess of Na,CO3, rubbing up the residue in water, and treating with acetic acid (Döbereiner, P. 28, 181; Topsoë, l.c.; cf. Wittstein, R. P. 74, 43). A hydrate PtO,II, II,O was obtained by Prost (Bl. [2] 46, 156) by adding water to a solution of PtO,II, in conc. HNO, Aq. A reddish-brown powder; dehydrated by heating gently; at a higher temperature gives Pt and O. Heated in H gives Pt. Sol. NaOHAq, HClAq, HNO,Aq, and H,SO,Aq. With acids forms platinic salts, PtX., where X = \(\frac{1}{2} \text{SO}_1, \frac{1}{2} \text{CO}_1, \frac{1}{2} \text{CO}_1, \frac{1}{2} \text{CO}_2, \frac{1}{2} \text{CO}_2, \frac{1}{2} \text{CO}_3, \frac{1}{2} \text{CO}_3, \frac{1}{2} \text{CO}_3, \frac{1}{2} \text{CO}_3, \frac{1}{2} \text{CO}_3, \frac{1}{2} \text{CO}_3, \frac{1}{2} \text{CO}_4, \frac{1}{2} \text{CO}_3, \frac{1}{2} \text{CO}_4, \frac{1} \text{CO}_4, \frac{1}{2} \text{CO}_4, \frac{1}{2} \text{CO}_4, NO, &c.; with strongly basic oxides forms platinates, PtO...xMO (v. Platinates, p. 281). Compounds with SnO and SnO, are described by Delachanel a. Mermet (C. R. 81, 370), Schneider (P. 136, 105), Lévy a. Bourgeois (C. R. 94, 1365), and Schützenberger (C. R. 98, 985). Pto,H, dissolves in solutions of certain molybdates and tungstates, forming platini molybdates and platini-tungstates (q. v. p. 283).

Platinum, oxychlorides of. When AgNO, Aq

together in the ratio H.PtCl,:4AgNO, a pp. is obtained which has the empirical composition PtCl2(OH)2.2AgCl; this substance may be regarded as a compound of the hydrated oxy-chloride PtOCl. H.O (Jörgensen, J. pr. [2] 16, 345). The pps. formed by CaOAq and BaOAq in PtCl Aq are supposed to contain oxychlorides of Pt (v. Johannsen, A. 155, 204).

Platinum, oxysulphide of, 2PtOS.H.O. PtS. slowly oxidises by exposure to air; by washing the product (to dissolve H.SO, and SO,) and drying in a stream of CO, a black powder is obtained having the composition 2PtOS.H₂O (perhaps HO.PtS.O.SPt.OH). This substance is an energetic oxidiser; H, CO, H,S, SO, take fire when brought into contact with it; NH, is absorbed and oxidised to HNO, and HNO, (E. von Meyer, J. pr. [2] 15, 1).

Platinum, phosphides of. Pt and P combine when strongly heated together. Schrötter obtained a grey metal-like mass, S.G. 8-77, to which he gave the composition PtP, by heating Pt black in vapour of P (J. 1879, 240). By heating by the property of th ing Pt and P to white heat, Clarke a. Joslin (Am. 5, 231) obtained Pt₂P₅; and by heating in a mufile they got Pt₂P, sol. aqua reqia but changed

to insoluble PtP.

Platinum, salts of. But few salts, excepting the halides, are known wherein Pt replaces the H of acids; Pt more frequently enters into the acid radicle, than the positive radicle, of salts.

Platinum, selenide of. By heating Pt and Se, Berzelius obtained a grey, infusible powder;

perhaps PtSe (Gm.-K. 3, 1081).

Platinum, selenocyanides of; for a double salt v. vol. ii. p. 348.

Platinum, silicides of. A white, crystalline, brittle solid, Pt, Si, was obtained by Guyard (Bl. [2] 25, 510) by heating together equal parts of Pt black and powdered crystalline Si (cf. Winkler, J. pr. 91, 203). According to Miles (Am. 8, 428), the conditions favourable to the formation of compounds of Pt and Si are a high temperature, the presence of a reducer such as CO, a basic substance such as MgO, and SiF, in contact with Pt (v. also Brown, Am. 7, 173).

Platinum, sulphides of. Pt and S combine

when heated together. Two sulphides have been isolated, PtS and PtS2; there is also evidence

of the existence of Pt.S.

PLATINUM MONOSULPHIDE PtS (Platinous sulphide). Obtained by heating Pt black and S. and volatilising excess of S, in absence of air; also by heating (NH,) PtCl, with S, out of contact with air, till NH,Cl and excess of S are volatilised; also by passing H2S into PtCl.Aq (Berzelius). Prepared in crystals by heating to redness a mixture of 1 pt. Pt, 1 pt. borax, and 10 pts. pyrites (Deville a. Debray, A. Ch. [2] 55, 215). A grey, lustrous solid; S.G. 6·2. PtS prepared in the wet way is a black powder. Unpared in the wet way is a black powder. changed in air, even when moist; unacted on by hoiling acids; loses S when heated in air, leaving Pt; reduction in II begins at 19°. A compound with CO—PtS.CO—was obtained by Mylius a. Förster (B. 24, 2438) by the action of H.S on PtCl,.CO.

PLATINUM DISULPHIDE PtS, (Platinic sul-Platinum, oxychlorides of. When AgNO,Aq phide). Obtained by passing H,S into is added to PtCl,Aq in the ratio PtCl,2AgNO, Na,PtCl,Aq, or by dropping H,PtCl,Aq into solution when AgNO,Aq and H,PtCl,Aq are heated tion of an alkali hydrosulphide. Also formed

by digesting, in a strong closed flask, 1 pt. PtCl4, 4 pts. alcohol, and 5 pts. CS, (Böttger, J. pr. 3, 274); and by decolourising H.PtCl.Aq by SO, and then heating in a scaled tube at 200° (Geitner, A. 129, 358). PtS. is also a product of the action of HClAq in air on Na Pt S or H₂Pt₄S_e (v. Thioplatinates, p. 281). Colloidal soluble PtS₂ was obtained by Winssinger (Bl. [2] 49, 452) by passing H2S into very dilute PiCl, Aq, and dialysing. A black solid; as obtained from Na,Pt,S, forms steel-grey needles, S.G. 5.27. PtS, prepared by one of the wet methods must be dried in absence of air, else it is partially decomposed. Heated out of air forms PtS, and Pt and S. Oxidised to sulphate by strong oxidisers, such as aqua regia, Cl, fuming HNO, molten KClO₃ or KNO₃. Freshly ppd. PtS₂ dissolves in alkali sulphide solutions forming thioplatinates (q. v.), from which solutions it is reppd. by acids. Clässon (J. pr. [2] 15, 193) describes a compound with EtSH.

PLATINUM SESQUISULPHIDE, Pt2S3. This compound is said to be formed, as a steel-grey, metal-like solid, S.G. 5.52, by the oxidation in air of H.Pt.S. (Schneider, P. 136, 105; 138, 604; 139, 661; 141, 519; 148, 633; 149, 381). Schneider also describes a compound 4PtS.PtS.

= Pt,S,.

Platinum, sulphocyanides of; v. vol. ii. p. 357; v. also Guareschi, Giorn. della R. Accad. di Med. 1891. No. 5; abstract in B. 25, Ref. 7.

Platinum, thiocarbide of. Pt₂CS₂. compound is described by Schützenberger (C. R. 111, 391). It is a black powder; obtained by passing a stream of N, or H, charged with CS, over spongy Pt heated to 400°-450°.

M. M. P. M. PLATINUM - AMMONIUM COMPOUNDS (Ammonio-platinum compounds. Ammoniacal platinum bases. Platinammines). When a solution of PtCl2 in HClAq reacts with NII3, more than one compound of the form PtCl, 2NH, is obtained. These compounds react with acids, oxidisers, &c., to form many derivatives containing Pt, N, H, and negative radicles, in which the reactions of Pt and NH, are more or less modified.

The platin-ammonium compounds may be regarded as salts of bases derived from two or more NH, groups, in which part of the H is replaced by Pt; thus PtCl. 2NII, may be called platoso-diammonium chloride, and formulated as NgH Pt.Cl. Similarly PtCl24NH3 may be

regarded as Pt<\(NH_2(NH_4)Cl\), and called ammo-

nium platoso-diammonium chloride. The compounds derived from PtCl, are regarded, in this scheme, as platini-ammonium compounds; thus, PtCl., 2NH, is Cl.Pt.NH_NII, Cl₂ (v. Hofmann, T. 1851. [2] 357; Weltzien, 4. 97, 19; Kolbe, J. pr. [2] 2, 217; Grimm, 4. 99, 67).

This view of the constitution of the compounds in question was opposed by Claus (J. pr. 63, 99), Blomstrand (B. 4, 40, 639, 673; 6, 1469), Jörgensen (J. pr. [2] 33, 489), and others. Jörgensen found that pyridine, N.C.H., forms a compound with platinous chloride similar to PtCl,4NH,; in this pyridine compound, which has the composition PtCl,4NC,H, the atoms of hydrogen cannot be in direct union with N; for the constitution of pyridine is known to be

HC. CH Now if the ammoniacal platinum HC CH

bases are all to be derived from NH, by substituting H by NH, groups, it is evident that the substituted H atoms must always be directly bound to N atoms. But the existence of the pyridine compound shows that this is not necessary. Hence PtCl₂4NII₃ may be regarded as Pt</ri>
NH₃NH₃Cl
NH₃NH₃Cl

The classification and nomenclature of the platin-ammonium compounds proposed by Blomstrand (Chemie der Jetztzeit, Heidelberg, 1869; B. 2, 202; 4, 40, 639, 673; 6, 1469) is now usually adopted. In the following formulæ R stands for a monovalent negative radicle. Blomstrand uses the term annine to distinguish these compounds from the amines, which contain the group NH...

Class I. PLATO- OF PLATOSO- COMPOUNDS. Series 1. Platosemiammines, RPtNH3R.

2. Platosammines, Pt(NH,R).

3. Platodiammines, Pt(NH3 NH3R)2. 4. Platosemidiammines,

Pt(NH3.NH3R)R.

5. Platomonodiummines. Pt(NH3.NH3R)(NH3R).

Series 2 and 4 are isomeric. Cleve has isolated two distinct aniline compounds, Pt(NH₃)₂·(C₆H₄NH₂)₂·R₂ (cf. Jörgensen, J. pr. [2] 33, 489).

Class II. PLATINI- OF PLATIN- COMPOUNDS. Series 1. Platinammines, R.Pt(NH.R).

2. Platinidiammines. R2Pt(NH3.NH3R)2.

3. Platinisemidiammines, R.Pt(NH, NH,R)R.

4. Platinimonodiammines R.Pt(NH3.NH3)R(NH3R).

5. Platinitriammines R2Pt(NH3.NH3.NH3R),

Series 1 and 3 are isomeric.

The prefixes mono, di, &c., are used to denote the number of NH, groups in direct union with one another, and not the number of NH, groups in union with the atom of Pt. As the compounds in Series 3 contain one diammine chain, (NH, NH,), they are called semidiammines; and as those in Series 4 contain a diammine and a monammine chain, they are called monodiammines.

Class III. DIPLATINUM COMPOUNDS. These contain 2 Pt atoms; the group Pt, may be divalent, tetravalent, or hexavalent.

Series 1.

Pt(NH,.NH,R) Diplatodiammines, Pt(NH..NH.R)

Series 2.

RPt(NH,.NH,R) Diplatosindiammines,

RPt(NH,.NH,R) Pt(NH,.NH,R) B.Pt(NH.NH.B) Series 3.

Diplatinammines.

RPt(NH.B). RPt(NH.R).

Series 4.

RPt(NH,NH,R), Diplatinidiammines, RPt(NH,NH,R)2

Iodides of platinum bases with 4 and 8 atoms Pt are also known; I,Pt,8NH,I, and I.Pta.16NH3.I16.

Many organic bases, such as aniline, pyridene. &c., can take the place of NH3 in these compounds, and the N of NH, is often replaceable by P or As.

Class I. Plato- or Platoso- compounds.

Series 1. Platosemiammines, RPtNH₄R. None of these has been isolated, but Cossa (B. 23, 2503) has obtained a compound which the bably contains platosemiammine chloride; the compound is 2PtNH₂Cl₂.Pt(NH₂),Cl₂.

Platosammines, Pt(NH₂),...

Pt(NH₂R)₂.

These compounds are generally obtained by heating the corresponding platodiammines, Pt(NH₂,NH₂R)₂, which thus lose 2NH₃; by heating with NH, Aq, platodiammines are re-formed; with oxidisers, platini- compounds are obtained.

PLATOSAMMINE CHLORIDE Pt.NH, Cl.NH, Cl. (Peyrone, A. 51, 1; 55, 205; 61, 178). Obtained heating Pt(NII3),Cl2 (plato-diammine chloride) to 250°, or by evaporating that compound with HClAq at 100° and dissolving out AmC in water; also by evaporating with HCl the solution of the corresponding nitrate or sulphate. Microscopic, sulphur-yellow crystals. S. 022 at 0°, '77 at 100'. Sol. NH, Aq, forming Pt(NH, NH, Cl), (platodiammine chloride); in aqua regia forms Cl2Pt(NH3Cl)2 (platinammine chloride). With AgNO Aq, in the ratio 2Pt(NH₂Cl)₂:AgNO₂, one half of the chloride remains unchanged and one half gives Pt(NH₃,NO₃)₂. Heated to 270°, the chloride is decomposed thus:

 $3Pt(NII_3Cl)_2 = 3Pt + 4NH_4Cl + 2HCl + N_2$

Platosemidiammine chloride

Pt(NH₂,NH₂Cl)Cl, and platodiammine chloride platinous chloride Pt(NH₂,NH₂Cl)₂, PtCl₂(Magnus' green salt), are isomeric or polymeric with platosammine chloride. Other compounds, perhaps also isomeric, were obtained by Peyrone (l.c.) and by Cossa (B. 23, 2503)

Grimm (A. 99, 67) obtained a double compound with AmCl; Pt(NH3Cl)22AmCl. Jörgensen (J. pr. [2] 33, 489) obtained the pyridine compound Pt(NC,H,Cl)₂; and also the mixed compound PtNC₂H₁Cl.NH₂Cl (v. also Hedin, Dissertation, Lund; B. 20, Ref. 108).

PLATOSAMMINE HYDROXIDE

Pt.NH3OH.NH3OH. Said to be obtained, as a the sulphate, Pt(NH,NH₃)SO, by BaOAq (Odling, C. N. 21, 269, 289). The compound thus formed may have been the isomeric platosemi-diammine hydroxide, OH.Pt(NH₂,NH₃OH). solution of Odling's hydroxide reacts strongly alkaline, absorbs CO₂ from the air, neutralises acids, decomposes salts of NH, giving off NH₂, and ppts. many metallic hydroxides from salts of the metals.

PLATOSAMMINE ONIDE Pt(NH_NH_)O.

grey solid, insol. water or NH, Aq; heated in a retort to 195° gives N, NH,, H,O and Pt. Obtained by heating platodiammine hydroxide (Pt[NH,NH,OH],) to 110° (Reiset, A. Ch. [3] 11, 417).

PLATOSAMMINE SULPHONATES and CHLORO-PHONATES Pt.NH, SO, M.NH, SO, M and SULPHONATES Pt.NH,Cl.NII,SO,M. Ammonium platosammine reaction of excess of Am, SO, Aq on Pt(NH, SO), (Peyrone, A. 51, 1; 55, 205; 61, 178). The salts of Ba, Co, Cu, Pb, Mu, Ni, Ag, Na, UO2, and Zn have been obtained. Ammonium platosammine chlorosulphonate, Pt.NIIsCl.NH3SO,Am.H2O, is obtained, in colourless rhombic tablets, by leading SO, into a boiling solution of Pt(NH,Cl), and neutralising with NH, Aq. If the neutralisation is omitted, platosammine chlorosulphonic acid, Pt.NH₂Cl.NH₂SO₂H, is obtained (Peyrone,

The other salts of the platosammine series which have been isolated are the following; wisch have been isolated are the following; M=Pt(NH₂):—bromide, MBr₂ (Jörgensen, J. pr. [2] 33, 521, 531, 535); cyanide, MCy₂ (Buckton, A. 92, 280); iodide, ML₂ (Cleve, Bl. [2] 7, 12; 17, 482; Reiset, A. Ch. [3] 11, 417); nitrate and nitrite, M(NO₃)₂, and M(NO₂)₂ (Cleve, l.c.); sulphate and sulphite, MSO₄, H₂O and MSO₄, H₂O (Cleve, L. 1); contact the contact of the cont l.c.); and sulphocyanide, M(CyS), (Buckton, l.c.). Substituted derivatives of the bromide, of the form Pt(NH2RBr)2 and Pt.NH3Br.NH2RBr, where R = Et, Me, or Pr, have been obtained (Jörgensen,

Series 3.—Platodiammines Pt(NII₃.NII₃R)₂. Formed by action of NH₃Aq on platinous salts, platosammine or platosemidia.nmine compounds. Easily lose NH, on heating, giving platosammine compounds. Give platinidiammine compounds by action of oxidisers.

PLATODIAMMINE CHLORIDE

Pt(NH₃.NH₃Cl)₂.H₂O (Reiset, A. Ch. [8] 11, 417). Sometimes called Reiset's first chloride. tained by the prolonged action of boiling NH3Aq on PtCl., Magnus's green salt (v. infra), platos-ammine chloride Pt(NH₃Cl), or platosemidiam-mine chloride Pt(NH₃NH₃Cl)Cl, precipitation by alcohol, and crystallisation from water. Also formed by reduction of platinidiammine chloride $Cl_2Pt(NH_3 NH_3Cl)_2$, by H_2S (Thomsen, J. 1868. 278). Large, colourless, tetragonal crystals; S. 25 at 16.50, more sol. hot water; insol. absolute alcohol and ether. Addition of H₂SO₄Aq, IINO₄Aq, or H₂C₂O₄Aq ppts. the corresponding sulphate, nitrate, or oxalate. By gently warming with IINO, Aq the salt (NO₃), Pt(NH₂, NH₂Cl), is formed; Cl, Br, and FcCl, Aq react similarly. At 240°-270° NH, is given off, and Pt(NH,Cl), is formed (v. Platosammine chloride, supra). Combines with PtCl., and PtCl., to form M.PtCl. and M.PtCl. respectively [M=Pt(NH4.NH4.Cl.)].
Compounds are known in which NH4.is wholly or partly replaced by pyridine, also by alkyl radicles (Jörgensen, J. pr. [2] 33, 489), and also by PEt, (Cahours a. Gal, C. R. 70, 1381).

Double compounds. Combines various metallic chlorides to form compounds of the form $M.XCl_2$, where $M = Pt(NH_1.NH_2Cl)_2$, and X=Pt, Cu, Pb, Hg, Sn, and Zn (v. Thomsen, J. 1868. 278; Buckton, C. J. 5, 213; Millon a.

Commaille, C. R. 57, 822).

The most important of these compounds is PLATODIAMMINE CHLORIDE PLATINOUS CHLORIDE, known as Magnus's green salt,

Pt(NH_NH_Cl)__PtCl__. This salt is obtained by the action of NH_Aq on PtCl_2 in HClAq, or on PtCl_1 in HClAq after passing in SO_2 till AmCl ceases to give a pp. (Magnus, P. 14, 242; Gros, A. 27, 241). Also by adding Pt(NH_1NH_Cl)_2 to PtCl_2 in HClAq. It is best prepared by making Am_PtCl_1, from PtCl_4 in HClAq treated with SO_2 and crystallised from AmClAq, and heating this with HClAq and NH_AQ (Claus, A'. 107, 138). Green, microscopic prisms or needles; insolwater, alcohol, and dilute HClAq. Digestion with hot NH_AQ forms Pt(NH_1,NII_5Cl)_2; Cl, Br, or HNO_AQ produces platinidiammines (Gros, Lo.; Raewsky, A. Ch. [3] 22, 278). Boiling with AgNO_AQ produces PtCl_2 and Pt(NH_1,NI_1,NO_2)_2. If the empirical formula nPt(NH_1)_cl_2 is given

AgNO₂Aq produces PtCl₂ and Pt(NH₂,NH₂NO₂)₂. If the empirical formula Pt(NH₃)₂(l₂ is given to Magnus's green salt, it is seen to be isomeric, or polymeric, with platosammine chloride Pt(NH₂Cl)₂, platosemidiammine chloride Cl₂Pt.NH₂NH₃Cl, platomonodiammine chloride platinous chloride 2[Pt(NH₂,Cl)(NH₂,NH₂Cl)]. PtCl₂,diplatosindiammine chloride Cl₂Pt₂(NH₂,NH₂Cl)₂, and with a double salt obtained by Cossa (B. 23, 2503), 2[Pt.NH₂,Cl₂]. Pt(NH₂,Cl₂).

PLATODIAMMINE HYDROXIDE Pt(NH₃,NH₃OH)... Sometimes called Reiset's first base (Reiset, A. Ch. [8] 11, 417). White, crystalline, deliquescent needles; by decomposing the sulphate by the proper quantity of BaOAq, filtering, and evaporating in vacuo. Solution in water is strongly alkaline, absorbs CO, from the air, and drives out NH₃ from NH₄ salts. NH₃ is not given off when an aqueous solution is boiled alone or with potash. Molts at c. 110°; at a higher temperature gives off NH₄ and H₂O and leaves platosammine oxide Pt(NH₃).20 (q. v. p. 293).

The other chief compounds of the platodiammine series are the following; M = Pt(NI_A); — carbonates, MCO, 4aq and M(CO₃H)₂ (Peyrone, A. 51, 14; Reiset, A. Ch. [3] 11, 417); chromates MCrO, and MCr₂O; bromide, MB₁, 3aq (Cleve); nitrate and nitrite, M(NO₄), and M(NO₂), 2aq (Feyrone, b.c.); phosphate, MHPO, aq (Cleve, Bl. [2] 7, 12; 17, 482); sulphate and sulphites, MSO₄, MSO. M(SO. H), 3aq (Cleve, Le.).

MSO., M(SO.H). 2aq (Cleve, l.c.).
Series 4 Platosemidiammines,
Pt(NH, NH, R)R. Generally formed from the
chloride by double decomposition: the chloride
is a product of the action of NH, Aq or
(NH,). 2Co, Aq on PtCl... Prolonged treatment of
the platosemidiammines with NH, Aq produces
diammine compounds. Jörgensen (J. pr. [2] 33,
489) has replaced NH, in these compounds by
alkyl radioles and by pyridine.

PLATOGEMIDIANMINE CHLORIDE Pt. Cl.

Sometimes called Peyrone's chloride. PtCl, is formed by the action of SO₂ on PtCl, in HClAq, and the solution is heated to boiling with excess of (NH₂).CO₂ until the red solution has become light-yellow and a greenish-brown pp. forms, when the liquid is rapidly filtered. The chloride separates as the liquid cools; it must be filtered off at once (else it may re-dissolve), and crystallised from boiling water (Peyrone, A. 51, 14; 55,

209; v. also Thomsen, Gm. K. 8, 1115; Cleve, Bl. [2] 7, 12, 17, 462). Small yellow crystals. S. 26 at 0°, 3°6 at 100°. Decomposes at 270°, giving off NH, and HCl. Boiling NH, Aq forms platodiammine chloride, Pt(NH, NH, Cl); Cl, Br, I, and some other oxidisers produce platinisemidiammine compounds, R, Pt(NH, NH, NH, R) With AgNO, and Ag, SO,, the corresponding nitrate and sulphate are formed.

It is doubtful whether the hydroxide Pt(NH,NH,OH)OH has been prepared; the compound obtained by Odling (C. N. 21, 269, 289) was this or the isomeric platosammine hydroxide, Pt(NH,OH), (v. Platosammine hydroxide, Pt(NH,OH), (v. Platosammine hydroxide, Pt(NH,OH), (v. Platosammine hydroxide, Pt(NH,OH), (v. Platosammine hydroxide, Pt(NH,NH,:-bromide, MBr.; chlorosulphonic acid, MCl.SO₂H (Cleve. L.c.); codide, MI.; nitrate and nitrite, M(NO₂); and M(NO₂); sulphate, MSO₃; double sulphites, MSO₃; 2X₂SO₃, X₂=2NH, Ba. Co, Ag₇; these may be regarded as compounds of sulphites with salts of the hypothetical platosemiammine sulphonic acid Pt(NH₃,NH₃,SO₃H)SO₃H.

Series 5. Platomonodiummines
Pt(NH_NH_1k)(NH_1k). Most of the salts of this
series are prepared from the double salt of the
chloride with PtCl...

PLATOMONODIAMMINE CHIORIDE PLATINOUS CHLORIDE 2Pt NH₃NH₃Cl. PtCl₂. This compound is one product of the action of NH₃Aq on PtCl₂ in HClAq; it is prepared by neutralising PtCl₂ in HClAq by (NH₄)₂CO₃Aq, heating to boiling, and adding (NH₁)₂CO₃Aq drop by drop, when it separates in small red tablets (Peyrone, A. 55, 209). Fairly sol. cold water, more sol. hot water. Boiled with NH₃Aq forms Magnus's green salt, Pt(NH₂,NH₃Cl)₂PtCl₂. Isomeric, or polymeric, with Magnus's green salt, platosammine chloride, and platosemidiammine

PLATOMONODIAMMINE CHLORIDE

Pt<\s\NI_s\NI_sCl \tag{NI_strong colourless} Obtained, in lustrous colourless crystals, by adding HClAq to an ice-cold solution of the nitrate.

PLATOMONODIAMMINE NITRATE

Pt<NH, NH, NO. Formed by decomposing the chloride in solution by AgNO, Aq, filtering, and evaporating. The sulphate

Pt $\langle {}_{NH_3}^{NH_3}NH_3 \rangle$ SO₄.H₂O is also known (v. Cleve, l.c.; Blomstrand, B. 4, 40, 639, 673; 6, 1469).

Class II. Platini or Platin- compounds. Series I. Platinammines, R.pt(NH,R). These compounds are formed by the addition of Cl, Br, or I to platosammines, or by the action of such oxidisers as HNO₂Aq on platosammines; they are generally changed to platinidiammines by heating with NH,Aq, and are reduced to platosammines by SO.Aq. The radicles in direct union with Pt are replaced with more difficulty than those in union with NH. The nomenclature is arranged to indicate, first, the nature of the radicles in direct union with Pt, and then those in direct union with NH.

those in direct union with NH₂.

I. Chloro: compounds Cl.Pt(NH₂R),
Ohloroplatinamming chloride Cl.Pt(NH₂Cl),
Formed by suspending platosamreine chloride

Pt(NH,Cl), in boiling water, and passing in Cl until the original citron-yellow particles are changed to microscopic yellow octahedra (Gerhardt a. Laurent, C. R. 30, 273), or until the liquid, which is yellow at first, begins to turn reddish. Aqua regia, or KMnO, Aq and HClAq, may be used instead of Cl (Odling, C. N. 21, 269, 289). A heavy, yellow, crystalline powder. S. 1 at 0°; 3 at 100°. Unacted on by boiling conc. HNO₃ or H₂SO₄; sol. boiling KOHAq without evolution of NH₃; sol. NH₃Aq, with formation of chloroplatinidiammine chloride, Cl.Pt(NH, NH, Cl.)2. The Cl is ppd. as AgCl only after long boiling with AgNO, Aq (Grimm, A. 99, 67).

CHLOROPLATINAMMINE NITRITE

Cl.Pt(NH3.NO)2. Ppd. in colourless rhombic plates by addition of excess of HClAq to solution of the nitrato-nitrite, (NO3) Pt(NH4, NO2)2, which is formed by boiling platosammine nitrite, Pt(NH3.NO), with HNO3Aq.

CHLOROPLATINAMMINE CHLORONITRITE Cl₂Pt(NH₄Cl)(NH₃.NO₂), is produced by the re-action of K,PtCl₄ and (NO₃)₂Pt(NH₃NO₂)₂.

II. Hydroxyl compounds

(OH), Pt(NH,R),.

HYDROXYL PLATINAMMINE HYDROXIDE (OII) Pt(NH₂,OII)₂. Yellow, lustrous crystals; by adding excess of NII₄Aq to a boiling solution of the nitrato-nitrate (NO3),Pt(NH3,NO3), and allowing to cool. Scarcely sol. water; easily sol. dilute acids. Boiling KOHAq does not evolve NH₃; decomposes above 130°, giving off NH₃ and H₂O, and leaving Pt (Gerhardt a. Laurent, C.R. 30, 273).

HYDROXYL PLATINAMMINE NITRATE (OH)₂Pt(NH₂NO₃)₂, 2aq. Crystalline pp. by decomposing Cl₂Pt(NH₂Cl)₂ by AgNO₂Aq. Not acted on by cold HClAq; evaporation with HNO₂Aq produces (NO₂)₂Pt(NH₂,NO₂)₂(G. a. L., l.c.; Cleve, Bl. [2] 7, 12; 17, 482).

HYDROXYL PLATINAMMINE SULPHATE

(OII)2Pt(NH3)2SO, aq. Formed as a pale-yellow, hard crust of needle-shaped crystals, by decomposing Cl_Pt(NH_2Cl)₂ by Ag_SO₄Aq. Evaporation with H_3O₁Aq produces the sulphate-sulphate, SO₄Pt(NH₂)₂SO₄ and Cl_Pt(NH₂Cl)₂ are produced (Cl_Pt(NH₂)₂SO₄ and Cl_Pt(NH₂Cl)₂ are produced (Cl_Pt(NH₂Cl)₂). produced (Cleve, l.c.).

The following salts of this series have also been The following satisfy this series have also been isolated: Bromo-bromide, Br.,Pt(NH,Br), (Cleve, l.c.); bromo-nitrite, Br.,Pt(NH,NO,), (Cleve, l.c.); iodo-iodide, I,Pt(NH,I), (Cleve, l.c.); nitrato-nitrate, (NO,),Pt(NH,NO,), nitrato-nitrite, (NO,),Pt(NH,NO,), nitrato-chloro-nitrite, NO,Cl.Pt(NH,NO,), (Cleve, l.c.); sulplato-sulphate, BO,Pt(NH,)2SO,3aq (Cleve, l.c.)

Lc.).
Series 2. Platinidiammines,
Generally form R₂Pt(NH₃NH₃R)₂. Generally formed by action of Cl. Br. I, and other oxidisers on platodiammines. A large number of these compounds is known. R attached directly to Pt may be the same as, or different from, R united directly to NH. The nomenclature is similar to that of the platinammine series. The radicles in direct union with Pt are removed with more difficulty than those united with NH,.

I. Chloro-compounds CIR.Pt(NH, NH, R)(NH, NH, R); the R's may be the same or different.

CHLOROPLATINIDIAMMINE CHLORIDE

Cl_Pt(NH_NH_Cl)₂. By passing Cl into a fairly conc. boiling solution of platediammine chloride, Pt(NH_NH_Cl)₂, till the liquid begins to turn red (Raewsky, A. Ch. [3] 22, 278); also by dissolving chloroplatinammine chloride, Cl.PP(NH,Cl),, in NH,Aq (Gerhardt a. Laurent, C. R. 30, 273). Pale-yellow, crystalline powder; scarcely sol. cold water, sl. sol. boiling water. HNO, Aq produces the chloro-nitrats Cl.Pt(NII, NII, NO,),; a little AgNO, Aq produces the chloro-hydroxyl-nitrate

Cl(OH)Pt(NH3.NH3.NO3)2; long boiling with CHOHJEU(NH₂,NH₂,NO₂)₂; long boiling with AgNO₂Aq is needed to remove all Cl as AgCl. Reduced by H.S, or action of Ag, to Pt(NH₂,NH₂Cl)₂ (Thomsen, J. 1868, 278; Jörgensen, J. pr. [2] 33, 489). Forms double compounds with PtCl₂ and PtCl₄ (Reiset, A. Ch. [3] 11, 417; G. a. L., L.c.; Cleve, Bl. [2] 7, 12; 17, 482).

The other chloro- compounds which are known are the following: Chloro-nitrate, Cl.Pt(NII, NH, NO₃)₂ (Gros, A. Ch. [2] 69, 204; Raewsky, A. Ch. [3] 92, 278; Hadow, C. J. [2] 4, 345); chloro-chloro-nitrite, Cl.Pt(NII, NII, NO₂)(NII, NII, Cl); chloro-hydroxyl-chloride, Cl(OII)Pt(NII, NII, Cl), (Cleve, Chloride, Cl(OII)Pt(NII, NIII, Cl), (Cleve, Chloride, Cl(OII)Pt(NIII, NIII, Cl), (Cleve, Chloride, Cl(OII)Pt(NIIII, Cl), (Cleve, Chloride, Cl(OII)Pt(NIIII)Pt(NIIII)Pt(NIIII)Pt(NIIII)Pt(NIIII)Pt(NIIIII)Pt(NIIIIIII)Pt(NIIII)Pt(NIIIII)Pt(NIIIII)Pt(NIIIII)Pt(NIII l.c.; Hadow, l.c.); chloro-hydroxyl-carbonate, Cl(OH)Pt(NH₃,NH₃)₂CO₃.H₂O (Raewsky, l.c.; Gros, l.c.); chloro-hydroxyl-chromate and di-chromate, Cl(OH)Pt(NH₃,NH₃)₂CrO₄ and chromate, Cl(OH)Pt(NH₂,NH₃)₂CrO₄ and Cl(OH)Pt(NH₂,NH₃)₂Cr₂O₂ (Cleve, l.c.); chlorohydroxyl-nitrate, Cl(OH)Pt(NH₃,NH₃,NO₃)₂, (Raewsky, l.c.; G. a. L., l.c.; Cleve, l.c.); chlorochromate and dichromate, and chloro-sulphate, MCrO₄, MCr₂O₇, and MSO₄, where Cl₂Pt(NH₂,NH₃)₂ (Cleve, l.c.).

II. Bromo-compounds. The following members of this class have been isolated (Cleve, l.c.); bromo-bromide, MBr₁; bromo-chloride, MCl₂; bromo-dichromate, MCr₂O₁; bromo-nitrate, M(NO₃)₂; bromo-phosphate,

M(PO,H.), 2aq (in these formulæ

M=Br.Pt(NH,NII,)); bromo-chloro-chloride,
BrClPt(NH,NH,Cl); bromo-hydrocyl-chloride
and nitrate, MCl, and M(NO₂), where and nitrate, MCl₂ an M = Br(OH)Pt(NH₄.NH₃)₂. and M(NO₂)₂,

III. Hydroxyl compounds. Hydroxylnitrate and sulphate, M(NO₂)2 and MSO₄, where

 $\mathbf{M} = (\mathbf{OH})_2 \mathbf{Pt}(\mathbf{NH_3.NH_3})_2.$

IV. Iodo-compounds. Iodo-iodide, MI2; iodo-nitrate, M(NO3)2; iodo-sulphate, MSO4; where M = LPt(NH3, NH4)2.

IV. Carbonato-compounds. Carbonatobromo - carbonate, carbonato - chloro - carbonate, and carbonato - nitrato - carbonate, Br. (CO,)R, and caronnais nations of some strong of the caronnais and (NO₃),CO₃R, where R = 2[Pt(NH_x,NH_y)₂).(CO₃)_x.

V. Nitrato-compounds (Cleve, l.o.; Ger-

V. Nitrato-compounds (Chardt a. Laurent, C. R. 30, 273); (NO₃).Pt(NH₂,NH₂Cl)₂.2aq; (NO₃).Pt(NH₂,NH₂Cl)₄; (NO₃).Pt(NH₂,NH₂CrO₄; (NO₃).Pt(NH₂,NH₂).CrO₅; (OH(NO₃)Pt(NH₂,NH₂).SO₂.aq; Cl(NO₃)Pt(NH₂,NH₂,NO₃)₂; VI. Nitrato-compounds

VI. Nitrito- compounds (Cleve, la.

Hadow, C. J. [2] 4, 345): (NO₂), Pt(NH₂, NH₂, NO₂); I(NO2)Pt(NH2.NH2.NO2)

VII. Sulphato-compounds (Cleve, Lc.): (SO₄)Pt(NH₂,NH₄)₂SO₄,aq; OH.Pt(NH₂,NH₂)₂Cl.2aq;

OH(SO,)Pt(NH,,NH,)2SO,.8aq; Br2(SO,)Pt(NH,.NH,),(SO,),2aq. Series 3. Platiniscinidiammines,

R.Pt(NH, NH, R)R. These compounds are isomeric with the platinammines, R,Pt(NH,R). They are generally formed by oxidising the platosemidiammines, Pt(NH3.NH2R)R.

CHLOROPLATINISEMIDIAMMINE CHLORIDE Cl.Pt(NH, NH, Cl)Cl. By chlorinating plato-semidiammine chloride, Pt(NH, NH, Cl)Cl, by Cl or aqua regia (Cleve, l.c.). Orange, crystalline powder; S. 33 at 0°, 1.52 at 100°. Not acted on by cone. H.SO, or alkali solutions.

The following salts of this series are known

(Cleve, l.c.):

bromo-bromide, Br₂Pt(NH₃,NH₃Br)Br; bromo-nitrite, Br₂Pt(NH₃,NH₃,NO₂)NO₂; chloro-nitrite, Cl_Pt(NH₃,NH₃,NO₂)NO₂; chloro-hydroxyl-nitro-nitrite, Cl(OH)Pt(NH₂,NH₃,NO₂)NO₂; trihydroxyl-nitrate, (OH)2Pt(NH3.NH3.NO3)OH; hydrocyl-sulphate, (OH), PtNH, NH, SO,

Series 4. Platinimonodiammines, R2Pt(NH3.NH3R)(NH3R). Of this series the following have been isolated (Cleve, l.c.): bromo-nitrate, Br.Pt(NH, NH, NO,)(NH, NO,); bromo-sulphate, Br.Pt(NH, NH, SO, NII,) aq; chloro-chloride, Cl.Pt(NH, NH, Cl)(NH, Cl); hydroxylnitrate. (OH), Pt(NH3.NH3.NO3)(NH3.NO3).aq; hydroxyl-bromo-nitrate,

(OH)BrPt(NH3.NH3.NO3)(NH3.NO3).aq; bromide, I.Pt(NH3.NH3Br)(NH3Br).

Series 5. Platinitriammines, R.Pt(NH₃,NH₂,NH₃R). This co This constitution is probably to be given to salts formed by electrolysing ammonium carbamate or carbonate solution, using electrodes of Pt (Drechsel, J. pr. [2] 20, 378; 26, 277; Gerdes, J. pr. [2] 26, 257). The salt formed as described is probably carbonato-platinitriammine carbonate. (CO₂).Pt NH, NH, NH, CO₃. By the action of HNO, H.SO, and HCl, respectively, on

this compound are obtained the nitratonitrate, sulphato-sulphate, and chloro-chloride, (NO₂₎₂, M.(NO₃)₂, SO₁, M.SO₂, aq, and Cl₂, M.Cl₂, where M = Pt(NH₁, NH₂, NH₃)₂,

Class III. Diplatinum compounds.

Pt(NH,.NH,R)

Series 1. Diplatodiammines, | Pt(NH₂.NH₄R) (Blomstrand, J. pr. [2] 3, 207). Cleve (l.c.) gives to these compounds the formula

Pt2(NH3)2(NH2)2R2 The following members of this series are known: chloride, MCl₂; hydroxide, M(OH)₂; mitrate, M(NO₃); and sulphate, MSO₄; where M = Pt₂(NH₃).

Series 2. Diplatosindiammines.

RPt(NH, NH,R)

The only compound of this RPt(NH..NH.R)

series is the chloride Cl2Pt2(NH2), Cl2 RPt(NH,R),

Series 8. Diplatinammines, BPt(NH.B), The only compound of this series is the iodide LPt₂(NH₃)₄I₄ (Cleve, l.c.); by treatment with HIAq, the compound Pt₄I₁₀(NH₃)₈ and Pt_sI₁₃(NH_s)₁₆ are produced. Series 4. Diplatinidiammines,

RPt(NH, NH, R)2

(Cleve, l.c.). The iodo-nitrate,

RPt(NH3.NH3R)2 I.Pt.(NH3),(NO3), is formed by reacting on I₂Pt(NH₃)₄(NO₃)₂ with NH₃Aq and treating the product with HNO₃Aq; most of the other compounds of the series are formed from the iodonitrate. Various classes of compounds of this series are formed by varying the composition of the radicles, R; the nomenclature is similar to that used for the platinidiammines. The compounds which have been isolated are bromonitrate, bromo-anhydronitrate, and bromosul-phate, $M(NO_3)_a$, $M(NO_3)_a$, and $M(SO_4)_x$ 2aq, where $M = Br_*Pt_*(NH_3)_s$; hydroxyl-chloride, di-Chromate, plosphate, and sulphate, MCl, aq, M(Cr,O,),, M(HPO,), and M(SO,), 2aq, where M = (OH), Pt₂(NH₃), iodo-iodide, anhydro-iodide, M = (OH)₂Pb₂[N n₃]s; vous-voucae, uningaro-voucae, nitrate, anhydronitrate, phosphate, and sulphute, M₁, M₂O, M(NO₃),4aq, M(NO₃)₂O, M(HPO₁)₂, and M(SO₄)₂, where M = I₂Pt₂(NH₃)₈; nitrato-nitrate, (NO₃)₂Pt₂(NH₃)₈(NO₈)₄·4aq. M. M. P. M.

PLATINUMS, FULMINATING. Various compounds of Pt, N, Cl, O, and H, all of which Various explode when heated, are formed by the action of KOHAq on (NH₄) PtCl₆, or by ppg. Pt(SO₄), with NH₂Aq and boiling the pp. with KOHAq (Proust, Gehlen's J. 1, 348; Döbereiner, G. A. 72, 194; Fourcroy a. Vauquelin, Gehlen's J. 1, 348; Davy, S. 19, 91). These compounds are classed together as fulminating platinums. E. von Meyer (J. pr. [2] 18, 305) classifies according to the quantities of Cl they contain; all contain Pt and N in the ratio of equal numbers of atoms: tetrachloro- compound Pt,N,Cl,Q,H₂₄, trichloro-oxy-Pt,N,Cl,(OH)Q,H₂₁₁,dichloro-Pt,N,Cl,Q,I₁,H₂₁, chloroxy- Pt,N,Cl(OH)Q₁₂H₂₂. Tetrachloro-ful-minating platinum is formed by adding KOHAq drop by drop to Am, PtCl, in the ratio 40KOH: Am.PtCl., and washing the pp. by repeatedly boiling with acetic acid solution and then with water. At 150° 4H.O is given off; explosion occurs at a higher temperature. Dilute H₂SO₄Aq produces H₂C₂O₄ and evolves CO₂. By treatment with KOHAq, or NH₂Aq, Cl, is easily removed, a third Cl is removed with difficulty, but the fourth Cl remains unattacked. M. M. P. M.

PLUMBAGO. A name sometimes given to graphite; v. Carbon, vol. i. p. 686.

PLUMBATES. Salts wherein PbO2 acts as acidic radicle, v. vol. iii, p. 132.

PLUMBITES. Salts wherein PhO acts as

PLUMERICS. Sames wherein the access ac acidic radicle, v. vol. iii. p. 129.

PLUMERIC ACID 0, H, O. (139°). Occurs as calcium salt in the milky juice of Plumeria acutifolia (Oudemans, A. 181, 154). Minute crystals (from water), v. sol. alcohol and ether, sl. sol. cold water. Yields salicylic acid on sl. sol. cold water. Yields salicylic acid on fusion with KOH. Reduced by sodium amalgam to crystalline 'hydroplumeria' acid C₁₉H₁₂O₄.—
K₄A'' 8aq. — Ca(H₂A''), 4aq. S. '5 at 20°. —
CaH₂A'' 5aq. S. '25 at 20°.—Ca₂(HA''), 8aq.—
Ag.H₂A'' aq. — Ag.HA'' 1¹/₂aq: needles (from water).

PODOCARPIC ACID C17H22O, i.e. C_1H_{1b} . C_0H_2 Me(OH). CO_2 H. Mol. w. 274. [188°]. [α]_p = 136°. Constitutes at least 90 p.c. of the resin found by de Vrij in the trunk of an old tree, Podocarpus cupressina, var. imbricata (Oudemans, A. 170, 213). Plates (from dilute alcohol), insol. water, v. sl. sol. benzene, v. e. sol. alcohol and ether. Dextrorotatory. Resolved at 300° into water and anhydride C34H aO, Yields methanthrene C15 II12 on distillation with zinc-dust. The Ca salt on distillation yields p-cresol, hydrocarpol, carpono C₀H₁₁, and methanthrol C₁₂H₁₂O. Br added to its alcoholic solution forms C₁₁H₂₂BrEtO₄(EtOH) [above 80°], which gives off alcohol when heated for some time, leaving C17, H20BrEtO3 [158°].

mne, reaving U₁H₂₀BTELO₂ [158*]. Salts.—NaA' 7aq. S. 33 at 21°. Needles.—
KA' 3aq.—KA' 4aq.—(NH₄)HA'₂ aq.—BaA'₂ 3aq.

AgA' 2 aq.

Matheliatics MA'₂ [1712]. Continu

Methyl ether MeA'. [174°]. Grains. Ethyl ether EtA'. [146°]. Needles.

Acetyl derivative C., H., AcO. Small needles (from dilute alcohol).

Nitropodocarpic acid $C_{12}H_{21}(NO_2)O_3$. [205]. Formed, as well as the di-nitro-acids, by the action of HNO₃ (S.G. 1³4). Small crystals, insol. water, m. sol. hot alcohol. May be reduced to unstable amido-podocarpic acid, which forms

C1, H2NO HCl laq.

Salts.—(NH₀)₂C₁,H₁₀NO₃4aq.—

K₂C₁,H₁₀NO₃5 baq. Red needles with green lustre, v. sol. water.—Na₂C₁,H₁₀NO₃9aq. Scarlet Plates. — BaC., H₁₀NO₃ 7aq. Red needles. — BaC., H₁₀NO₃ 3aq. — Rad v. 4aq : yellow needles, sl. sol. water. — CaC., H₁₀NO₃ 4aq : orange needles.

Di-nitro-podocarpic acid C1, H2 (NO2)2O3. [203°]. Pale-yellow crystals, insol. water, m. sol. alcohol. -- Salts: K2C17H18N2O, 5aq. Crimson needles, with green reflex. BaC1, H18N2O, 4aq. -Ag2C1,H18N2O, 4aq: orange pp.

Sulpho-podocarpic acid C1,H (SO1H)O18aq. Got by warming with H.SO.. Amorphous mass. Salts: Na,A" 7aq: easily soluble rosettes.—Ba(HA"), 6aq. — BaA" 8aq: white laminæ. — CaA" 7aq: thin lamine.

Hydrocarpol $C_{1a}H_{20}O$. (220° in vacuo). A product of the distillation of calcium podocarpate. Viscid oil, v. sol. alcohol and ether. Yields p-cresol, carpene, and methanthrol $C_{15}H_{12}O$ [122°] when distilled. Methanthrol is crystalline, sol. KOHAq.

PODOPHYLLIN. The resin extracted from the root of Podophyllum pellatum (Guareschi, B. 12, 683; G. 10, 16; Busch, Ph. [3] 8, 443; Senier a. Lowe, Ph. [3] 8, 445). It contains bitter and physiologically active 'picropodophyllin' crystallising in needles [200°-210°], and several resins, e.g. 'podophyllo- quercetin' [247°-250°] and 'podophyllic acid' (Podwissotzky, Ph. [3] 12, 1011).

POLYCHROÏTE v. SAFFRON.

POLYMERISM; a term generally applied to the phenomens of the existence of more than one substance having the same composition, and related in properties, but with different molecular weights; v. Isomerism, vol. iii. pp. 79-81. M. M. P. M.

POLYPORIC ACID C, H, O,. [above 800°]. Occurs in a fungus belonging to the genus Polyporus, which grows on the bark of diseased or dead oaks. The fungus is yellow, but is turned violet by ammonia (Stahlschmidt, A. 187, 177; 195, 365). Bronzed tables (from alcohol), insol. water, ether, benzene, CS2, and HOAc, sl. sol. chloroform and alcohol. Alkalis form purple solutions, decolourised by zine-dust. Yields a tetrahydride when boiled with conc. KOHAq. Wields benzene on distillation with zino-dust. Conc. HNO, forms C_1 , H_1 , (NO.), O_4 , [230°]. KClO, and HCl give C_1 , H_1 , C, O_4 , [108°] and C_1 , H_2 , C, O_4 [110°].

Salts .- K, A" 2aq: purple monoclinic crys. tals.—Na Λ'' 2aq : violet needles. — $(NH_4)_2\Lambda''$ 2aq.—Ba Λ'' 4aq.—Ba Λ'' 2aq.—Sr Λ'' 4aq.—Sr Λ'' aq. -CaA" 3aq: pale-violet needles. MgA" 3aq.-Ag A": insoluble pp.

Methylether McA". [187°]. Ethylether Et,A". [134°]. Needles. Diacetyl derivative C, H, 2Ac,O. [205°]. Yellow needles, sl. sol. alcohol

Hydride C₁₈H₁₈O₄. [163°]. Formed, together with the acid C₂₀H₁₈O₂ [156°] which [163°] yields Ag,A", by boiling polyporic acid with cone. KOHAq. White crystalline powder (from hot water), sol. alcohol.—Na,A" 4a,—BaA".—MaM", 6aq.—Ag,A": crystalline pp.
POPPY OIL. The oil expressed from the

seeds of Papaver somniferum contains glycerides of linoleic, stearic, and palmitic acids (Oudemans, J. 1858. 304; 1863. 333; cf. Mulder, J. 1865, 323).

POPULIN is the Benzoyl derivative of SALICIN. PORPHYRINE C₂₁H₂₂N₃O₂. [97°]. Occurs, together with alstonine and alstonidine, in the bark of Alstonia constricta (Hesse, A. 205, 366). White amorphous substance, sol. alcohol, ether, and chloroform. Conc. H.SO, gives a purple solution. Its acid solutions exhibit blue fluorescence. -B'2H2PtCl, 4aq.

POTASH. Potassium hydroxide, q. v., p.

POTASSIUM. K. At. w. 39-04. Mol. w. probably 39·04 (Bansay, C. J. 55, 521; v. infra). M.P. 58° (Quinoke, P. 135, 642); 62·5° (Bunsen, A. 125, 368). B.P. 719° -731° (Carnelley a. Williams, C. J. 35, 563); 667° (Perman, C. J. 55, 326). S.G. 865 at 15° (Gay-Lussac a. Thánard); 875 at 13° (Baumhauer, B. 6, 655). V.D. not known with certainty; v. infra, molecular weight. S.H. from -78° to +10° 166 (Regnault, A. Ch. [3] 26, 286). C.E. (linear, 0'-50') 00008415 (Hagen, Verhandl. d. physikal. Ges. su Berlin, 1882. No. 13). Volume at to vol. at 0° 1882. No. 13). $(1 + .00023935t + .00000020925t^2)$ for interval 10° to 95° (Hagen, l.c.). E.C. at 0° (Hg at 0° -1) 11.23; at 100° (liquid) 5.586 (Matthiessen, P. 100, 177). Refraction-equiv 7.51 (Kanonnikoff, J. R. 1884 (1), 119). The emission-spectrum is characterised by a line K, in the extreme red, and a line Ks in the violet; for measurements of all the chief lines v. B. A. 1884. 436; for the absorption-spectrum v. Roscoe a. Schuster, C. N. 29, 268. H.C. [K²,O] = 66,050 (Woods, P. M. [4] 2, 268).

Occurrence. - Compounds of K are widely distributed in large quantities. Felspar, mica, &c., contain silicates of this metal; carnallite, sylvine, &c., contain KCl; alum-stone and other

minerals contain K₂SO₄; saltpetre is chiefly partly filled with mineral naphtha, and having KNO₂. Sea-water contains c. 5 to 7 g. KCl an opening through which an iron rod may be per litre. Potassium salts, e.g. acid tartrate and passed to clear the tube which carries the K oralate, are found in plants. Animals contain salts of K, chiefly phosphate and chloride.

Marcska. A. Ch. [3] 35, 147). Castner C. N.

Historical.—Polash was decomposed by Davy (T. 1808. [1] 5) in 1807, by passing the electric current from a Volta-pile of 200 plates, through a piece of potash placed in a Pt basin. Gay-Lussac a. Thénard, in 1808, reduced potash and obtained the metal, by heating it to whiteness with iron filings (A. Ch. 65, 325). In the same year Curaudan (A. Ch. 66, 97) showed that charcoal could be used instead of iron. Brunner (S. 38, 517) made this process applicable on the large scale, and B.'s method was modified by several workers, especially by Donny a. Mareska

(A. Ch. [3] 35, 147).

Formation.—1. By electrolysing KOH. The most effective method is to place a little cone. KOHAq, with pieces of solid KOH in it, in a Pt basin, to connect this with the negative pole of a powerful battery, to pour a little Hg into the basin, and place therein the wire from the positive pole. The K which is thus formed amalgamates with the Hg; the amalgam, after drying, is heated in a small retort, along with a little mineral oil, which drives out the air, and the K remains when the Hg has been distilled off .- 2. By electrolysing a molten mixture of KCl and CaCl2 in the ratio 2KCl: CaCl2. Temperature is arranged so that a solid crust remains on the surface of the molten mixture. Electrodes of gas-coke are used. After electrolysis the mixture is allowed to cool for twenty minutes, and the contents of the crucible are scraped out under petroleum (Matthiessen). Linnemann electrolyses molten KCN (J. pr. 73, 415).—3. By heating KOH to redness with iron filings or charcoal.-4. By heating an intimate mixture of K,CO, and C, or a mixture of K,CO, or KOH, C, and very finely-divided iron (Castner, C. N. 54, 218).-5. By heating sulphide of K with iron filings (Dolbear, C. N. 26, 33).-6. By heating potash with sodium under petroleum to c. 170' (Williams, C. N. 3, 21).-7. By the action of Na on dry molten K acetate (Wanklyn, C. N. 3, 66).

Preparation. -- An intimate mixture of K.CO. and C is formed by heating cream of tartar (K-H tartrate) in a closed crucible. The mixture is then strongly heated in an iron bottle, connected with a flat receiver about 30 centim. long, 12 centims. wide, and 6 centims. from the inner surface of one side to that of the other; this receiver is made of two pieces of sheet iron (about 4 mm. thick) screwed together, and has an opening at the end farthest from the retort, to allow the escape of CO. The reaction may be represented thus: $K_2CO_3 + 2C = 2K + 3CO$. The K distils over and condenses in the receiver; when full the receiver is removed, plunged under mineral oil and there opened, and the K is removed by a chisel. K combines with CO at a red heat to form a black, very explosive substance; the more rapidly the distilled K is cooled the less of this explosive compound is formed. The distilled metal is purified by wrapping it, when under oil, in a piece of linen, heating the oil to c. 65°, and pressing the molten K through the linen; the metal is then redistilled, from an iron bottle, into a copper tube

partly filled with mineral naphtha, and having an opening through which an iron rod may be passed to clear the tube which carries the K from the bottle into the receiver (Donny a. Marceka, A. Ch. [3] 35, 147). Castner (C. N. 54, 218) uses as reducer a mixture of C and a metallic carbide, or a mixture of very finely-divided metal and C (conveniently prepared by heating a mixture of $Fe_{\chi}O_{\chi}$ and tar in a covered vessel), and heats in an iron crucible with an exit-tube passing through the lid. The reaction, using KOH, Fe_{χ} and C, may be formulated as $3KOH + Fe_{\chi} + 2C = 3K + Fe + CO + CO_{\chi} + 3H$.

Properties. - A silver-white, lustrous metal. As soft as wax at ordinary temperatures, brittle at 0°, melts at c. 60°. Boils when heated in a stream of H to c. 700°, and forms a brightgreen vapour. A sublimate, in a very thin film on glass, shows a rich purple colour in transmitted light (Dudley, C. N. 66, 163; Newth, N. 47, 55). Crystallises in quadratic octahedra, which have a greenish-blue sheen. These crystals are obtained by melting K in a glass tube, narrowed at one place, and filled with coal-gas, and allowing the semi-solidified metal to flow slowly through the constricted part of the tube (Long, C. J. 13, 122). Sol. liquid NII, forming a blue liquid, from which the metal is obtained by allowing the NH, to evaporate (Seeley, C. N. 23, 169; v. Potassammonium, p. 299). Combines very rapidly with O; on exposing a freshly-cut surface to air, oxidation occurs at once. composes cold water rapidly. K must be kept under a liquid free from O, such as mineral naphtha or rock-oil.

The atomic weight of K was determined by Berzelius, Penny, Marignac, Pelouze, Millon, Faget, and Maumené, from 1813 to 1846, by reducing KClo₃, KClO₄, and KIO₅ to KCl and KI, and by converting KCl, KBr, and KI to AgCl, AgBr, and AgI. The researches of Stas, in 1860 and 1865, have determined the at. w. with great accuracy. Stas heated KClO₅, thus getting KCl, decomposed KClO₅ by HClAq, determined the ratio of KCl and KBr to Ag required for complete ppn., converted KCl into KNO₅ and KBr into AgBr, and determined the ratio of KBr to AgNO₇ required for ppn. (Stas, Rech. 69, 70, 91,

118; Nouv. R. 244, 303).

The molecular weight of K is not known with certainty. Dewar a. Dittmar (C. N. 27, 121) and Dewar a. Scott (Pr. 29, 206, 490) determined the V.D. of K at c. 1000°; the earlier results pointed to a mol. w. of c. 90, and the later numbers to a value c. 45. V. Meyer (B. 13, 391) showed that the results were untrustworthy, as vapour of K attacks glass vessels. It has also been shown that vessels of Cu, Ag, Pt, or Fe cannot be used (Ricth, B. 4, 807; Meyer, Lc.). Ramsay (C. J. 55, 521) attempted to find mol. w. of K by dissolving in Hg, and finding the decrease of the vapour-pressure of Hg thereby produced. Assuming the mol. w. of liquid Hg to be 200, and also assuming that equal vols. of dilute solutions contain equal numbers of molecules, the results gave mol. w. of K as 29:1 and 30°2; it seems probable that the mol. of K is monatomic.

The only compound of K whose V.D. has been determined is KI; in this molecule the atom of K is monovalent.

K is a very strongly positive element. In all

its compounds it reacts as a metal, and does not enter into the composition of any negative radicles. K forms very few basic salts, and no oxyhaloid compounds; its halide compounds are very stable towards heat. K is closely related to Cs, Li, Na, and Rb (v. Alealis, METALS OF THE, vol. i. p. 114).

Reactions .- 1. Heated in dry air or oxygen, K₂O and K₂O₄ are formed (v. Oxides, p. 304).—2. At about 300° K absorbs hydrogen readily, probably forming K₂H (v. Hydride, p. 301).— 3. Combines with chlorine, bromine, and iodine when heated (v. Chlorides, bromides, iodides, pp. 299, 300, 302) .- 4. Forms compounds with sulphur, selenion, and tellurium when heated (v. Sulphides, selenides, tellurides, pp. 305, 306).-5. Combines with phosphorus (v. Phosphide, p. 305) .- 6. Alloys with several metals (v. Alloys, infra). -7. Reacts rapidly with water, forming KOHAq and H .- 8. Heated with hydrogen sulphide forms KHS (v. Hydrosulphide, p. 302). — 9. Dissolves in liquid ammonia (Seeley, C. N. 23, 169; v. infra, Potassammonium). Heated in dry ammonia gas, KNII, is formed (v. Amide, infra). - 10. Combines with carbon monoxide to form KCO (v. Carbonyl compound, p. 300). At red heat decomposes CO with separation of C.— 11. Decomposes carbon dioxide, and nitrous and nitric oxide, when strongly heated with these compounds. - 12. Reacts with moist carbon dioxide to form K2CO3 and HCO2K (Kolbe a. Schmitt, A. 119, 251).-13. Decomposes silica and boric acid, when heated with these compounds, probably forming silicide and boride (q. v., pp. 299, 305).

Potassium, alloys of. Alloys of K with most metals are known; K alloys easily with the The alloys generally more fusible metals. oxidise in air, and decompose cold water. K forms amalgams with Hg; according to Joannis (C. R. 113, 795), Hg₁₈K is formed by letting potassammonium (q. v.) in liquid NH, drop on to Hg. For polarisation of K amalgam in KCIAq against Zn amalgam v. Le Blanc, Z. P. C. 5, 467. For supposed alloy with NH., v. infra, POTASSAMMONIUM.

Potassium, aluminate of; v. vol. i. p. 141.

Potassium amide, KNH₂. Gay-Lussac a. Thénard (G. A. 29, 135; 32, 23) obtained dark olive-green crystals by heating K in dry NH3. Baumert a. Landolt (A. 111, 1) confirmed G. a. T.'s formula KNH₂. The compound is formed by passing dry NH₃ into a flask of c. 50 c.c. capacity, fitted with a cork carrying an inlet and exit tube, quickly throwing in pieces of K, continuing the passage of NH,, and heating very gently till the metal just ceases to dissolve in the greenish-blue liquid that is formed; on cooling, a yellowish-brown solid is obtained. KNH, is a non-conductor of electricity. Melts at a little over 100°, at a higher temperature NH, is given off, along with H and N, and K,N remains (v. Potassium nitride, p. 304). Burns when heated in O, or heated to redness in air, giving N and KOH; decomposes in moist air to KOH and NH.; must, therefore, be kept under rock oil. Reacts energetically with water, giving NH, and KOHAq.

Potassium-ammonium or Potassammonium. By evolving dry NH, from AgCl.xNH, in a

Faraday tube containing K in the other end, Weyl (P. 121, 697) obtained a substance which he regarded as an alloy, or compound, of K and NH. Seeley (C. N. 23, 169) regarded the blue liquid formed by dissolving K in liquid NH, as a solution, inasmuch as K was obtained again when the NH, was allowed to evaporate. Joannis (C. R. 109, 900, 965; 110, 238) examined the vapour-pressures of a solution of K in liquid NH, and also the thermal phenomena attending the formation of the solution. He found the vapour-préssure to decrease till a certain value was reached, when it became constant, provided temperature was not changed; on removal of more NH, a copper-red solid separated, and thereafter NII, was given off at constant pressure, till only K remained. This last part of the process was regarded by J. as a dissociation of NHaK; analysis showed this ratio (NHaK) to be always at ained when the final part of the change commenced. The heat of formation of NH₃K is given by J. as 6,300 when NH₄ is gas and K solid, and as 1,900 when NH, is liquid and K solid. Joannis (C. R. 113, 795) found that NII, K in liquid NH, is decomposed by Sb, Pb, and Hg, but not by Al, Cu, Ag, or Zn; by dropping the liquid on to Hg, and washing the product with liquid NH, he obtained a crystalline amalgam Hg, K.

By measuring the depression of the vapourpressure of liquid NH, by solution of K therein, J. concludes that the mol. formula of potassammonium is N.II.K. (C. R. 115, 820).

Potassium, antimonide of. Probably SbK, A greyish-white, lustrous solid; decomposes water, giving KOH, Sb, and H. Formed by heating the elements together, or by fusing Sb,O, with K,CO, and C.

Potassium, antimonates of; v. vol. i. p. 286. Potassium, arsenates of; v. vol. i. p. 309.

Potassium, arsenites of; v. vol. i. p. 306.

Potassium, auricyanide of; v. vol. ii. p. 332. Potassium, borates of; v. vol. i. p. 529.

Potassium, boride of. The brown solid

formed when boric acid is reduced by heating K may contain a compound of B and K.

Potassium, borofluoride of; v. vol. i. p. 526. Potassium, boronitride of. By very strongly heating a mixture of 7 parts B₂O₃ with 20 parts KCN, Balmain (J. pr. 27, 422) obtained a white, infusible solid; insol, water or KOHAq; decomposed by boiling aqua regia, leaving BN (vol. i. p. 527); heated in steam gave off NH, and left KOH and boric acid.

Potassium, bromide of, KBr. Formula probably molecular, from analogy of KI. Melts at 699° (Carnelley, C. J. 33, 279). S.G. 2.695 to 2.72 at 4° (Schröder, P. 106, 226); 2.712 at 12.7° (Clarke's Tables of Spec. Gravities, 2nd ed., 31); 2·199 fused (Quincke, P. 138, 141); v. also Spring (B. 16, 2724). S.H. (16° to 98°) 11322 (Regnault, A. Ch. [3] 1, 129). Vol. at 40° - vol. at 0° (1+00012602) (Fizeau, C. R. 64, 814). 8. 53·48 at 0°, 64·6 at 20°, 74·62 at 40°, 84·74 at 60°, 93·46 at 80°, 102·04 at 100° (Kremers, P. 25, 119); Coppet (A. Ch. [5] 30, 411) gives S. 54.43 + 5128t where t varies from - 18.4° to 110°. Gerlach (Fr. 8, 285) calculated the following from Kremer's data:

	8.G.	KBrAq	
б р.с.	1.037	30 p.c.	1.256

production of much heat (v. Balard, Merz, a. Weith, B. 6, 1518) .- 2. By treating BrAq with weith, B. 6, 1016).—2. By treating Braq with iron filings and ppg. with K.CO.3.—3. By neutralising HBrAq by KOHAq or K.CO.3Aq, and evaporating.—4. By decomposing CaBr.Aq by K, SO, filtering after 12 hours, adding K, CO as long as turbidity is produced, filtering, and evaporating (Klein, A. 128, 237).

Preparation.- A moderately conc. solution of KOH, free from K₂CO₂, is prepared from pure K₂CO₂ and pure CaO (v. Potassyum hydroxide, p. 302); to this solution Br is added, little by little, till the liquid is slightly yellow; very finely-powdered charcoal, equal to about one-tenth of the quantity of Br used, is added, and the liquid is evaporated to dryness (6KOHAq + 3Br₂ = 5KBrAq + KBrO₃Aq + 3H₂O); the dry residue is well powdered, and heated to dull redness in a closed crucible for some time $(2KBrO_3 + 3C = 2KBr + 3CO_2)$; the residue is extracted with warm water, the solution is filtered, and evaporated to the crystallising point.

Properties and Reactions. - KBr crystallises in very lustrous, white cubes, sometimes elongated to prisms or flattened to plates; it has a strongly saline taste. Easily sol. water, with considerable lowering of temperature; [KBr,Aq] consideration towering of temperature; [ABF,Aq] = -5,080 (Th. 3, 235). Chlorine reacts with KBrAq to give KClAq and Br; Br is not set free by H₂SO₄ containing N₂O₃, nor by KNO₂Aq + dil. H₂SO₄Aq. KBr heated with possible the containing the containing N₂O₃. tassium chromate and sulphuric acid gives off Br; KCl under similar conditions gives CrO2Cl2. Conc. sulphuric acid produces HBr, Br, and SO.: the amount of HBr (the primary product of the reaction) thus decomposed varies very nearly in proportion to the quantity of IL₂SO₄ used; if the H₂SO₄ is in such large excess that the water formed in the reaction causes no sensible dilution, only SO, and Br are produced; by using dil. H.SO.Aq (c. 30 p.c.) a mere trace of Br is obtained, the products being almost wholly KHSO, Aq and HBrAq (v. Addyman, C. J. 61, 94). Hypochlorous acid solution produces KClAq and KBrO, Aq, with evolution of Br and Cl. Potassium permanganate solution has no action even when boiled; but Br is set free if a little H,SO, is added, even without warming, the decomposition being soon completed (Hempel, A. 107, 160). Fusion with potassium chlorate produces KBrO.

Combinations .--With many bromides of less positive metals to form double salts; some of these are best regarded as K salts of acids containing Br and a metal less positive than K, e.g. AuBr, KBr is best looked on as KAuBr, (v. the various metallic bromides). Also with iodina bromide, to form KBr.IBr (Wells a. Wheeler, Am. S. [3] 48, 475). Also with some metallic chlorides; thus SbCl, forms SbCl, 3KBr identical with SbBr. 3KCl, and therefore to be regarded as SbK,Cl,Br, (Atkinson, C. J. 48, 290). Feit

(J. pr. [2] 39, 373) describes MgBr. KBr. 6aq, analogous to carnallite (MgCl. KCl.6aq). Schiff (A. 228, 72) describes a compound with arsenious

Potassium tribromide KBr., According to Berthelot (A. Ch. [5] 21, 370), orange crystals of this composition are formed by adding Br to KBrAq; no analyses are given. The substance KBrAq; no analyses are given. The substance decomposes rapidly. B. gives [KBr,Br²] = 2940.

Potassium, carbonyl compound of. (Carbonic oxide potassium.) The black solid formed in the preparation of K was thought by Berzelius (P. 4, 31) to be a carbide; Liebig (A. 11, 182) found that the same compound was formed by passing CO over K heated just to melting; Brodie (C. J. 12, 269) confirmed Liebig's result, and determined that one molecule CO is absorbed for each atom K; hence the empirical formula is probably KCO. This substance is extremely explosive; many serious accidents have occurred with it. If the CO used is quite dry, and the substance is washed rapidly in alcohol as soon as it is prepared, the residue is not nearly so explosive (Nietzki a. Benckiser, B. 18, 1833, where details of the method of preparation are given); probably the alcohol dissolves out unchanged K. Potassium carbonyl is a greyish solid; on standing in air it becomes yellowish and very explosive; it dissolves in water, with evolution of much gas (according to E. Davy [A. 23, 144] this gas contains C.H., and generally with combustion or explosion; heated to redness it is resolved into K and CO. By exposure to moist air, or by other processes of oxidation, a series of organic compounds is obtained (v. CROCONIC ACID, vol. ii. p. 275; HEXA-OXY-BENZENE, vol. iii. p. 678; Tetra-oxy-quinone, vol. iii. p. 771; RHODIZONIC ACID, this vol.).

Potassium, chloride of, KCl. Formula probably molecular, from analogy of KI. Melts at (Carnelley, C. J. 33, 279). S.G. 1 9775 at 4º (Playfair a. Joule, C. S. Mem. 2, 401); 1.9453 at 15° (Stolba, J. pr. 97, 503); 1.612 at M.P. (Braun, C. J. [2] 13, 31); 1.87 fused (Quincke, P. 135, 642); v. also Spring (B. 16, 2721). S.H. 14° to 99 17295 (Regnault, A. Ch. [3] 1, 129; v. also Kopp, T. 155 [1] 71). Vol. at $40^{\circ} = \text{vol}$. 2. at 80 Appp, F. 155 [1] 71). Vol. at 40° = Vol. at 0° (1 + 00011408) (Fizeau, C. R. 64, 314). S. 32 at 10°, 334 at 15°, 34·7 at 20°, 37·4 at 30°, 40·1 at 40°, 42·8 at 50°, 45·5 at 60°, 48·3 at 70°, 51° at 80°, 53·8 at 90°, 56·6 at 100° (Mulder, Scheikund, Verl. 1864. 39); Coppet (A. Ch. [5] 30, 411) gives S. $28.51 + .2837t^{\circ}$, where t° varies from -11° to 109° . S. at 0° in alcohol is given in following table (Gerardin, A. Ch. [4] 5, 139); where S.G. of alcohol is at 0°, and $S+t^\circ$ is solubility at t° (cf. Schiff, A. 126, 167):

Alcohol S.G.	s.	t°	Alcohol S.G.	S.	to
.9904	$23 \cdot 2$.27	9573	7.1	.162
.9848	19.4	.255	.9390	4.2	·125
.9793	15.7	.233	8767	1.89	.061
.9726	11.9	.205	1		_

Gerlach (Fr. 8, 281) gives the following data:

			8.G.	KCLAq			
1	per	cent.	1.0065	20	per	cent.	1.1861

15			1.1004				

H.F. [K,Cl] = 105,610; [K,Cl,Aq] 101,170 (Th. 3, 285). 30 parts KCl dissolved in 100 parts water at 18.2° lower the temperature to '6°, i.e. through 12.6° (Rüdorff, B. 2, 68). Solution of 1 g. KCl in 100 g. water freezes at - 446°; saturated solution freezes at -10.9° (Rüdorff, P. 114, 63: 122, 337). Saturated solution boils at 108°.

Occurrence. - In small quantities in sea-water, and in some mineral springs. As chloride in sulvine; as double chloride, especially as carnallite KCl.MgCl..6aq. In crude pearl ash, in plant ash, and in kelp.

Formation .- 1. By the direct union of the elements; K burns in Cl at the ordinary temperature. - 2. By heating K in HCl gas. - 3. By passing Cl over KOH or KI heated to redness. -4. By the action of HClAq on KOH or K,CO,.-5. By decomposing various metallic chlorides by fusion with K.

Preparation.-1. Commercial KCl is prepared chiefly from carnallite. The mineral is dissolved in warm water, heated by steam to c. 120°, and allowed to cool; at 60°-70°, MgSO, aq, CaSO, and NaCl separate, and on further cooling c. 70 p.c. of the KCl is obtained; the crystals of KCl are washed with a little cold water, to remove NaCl and MgCl,, and a product containing c. 95 p.c. KCl is thus obtained (for details v. Dic-TIONARY OF APPLIED CHEMISTRY) .- 2. Pure KCl is prepared by neutralising pure HClAq by pure KOH or K,CO,, evaporating to the crystallising point, and recrystallising from water.

Properties.—White salt, crystallising in cubes.
Saline taste. Unchanged in air. Decrepitates when heated; melts at c. 740°, and volatilises at a higher temperature. Fairly sol, water or aque. ous alcohol; insol. absolute alcohol, or conc. HClAq; sol. in 20 p.c. KC₂H₂O₂Aq.

Reactions. -1. With acids, KCl generally

gives K salt of the acid used and HCl .- 2. Said to combine with sulphuric anhydride, and chromic anhydride, probably forming SO. Cl.OK and CrO, Cl.OK respectively (H. Rose, P. 38, 117) .- 3. Fused with potassium, in H, a blue substance is formed, supposed by H. Rose to be a subchloride (P. 120, 15). What is probably the same substance is formed during electrolysis of molten KCl (Bunsen a. Kirchoff, P. 113, 344). 4. For action of water and oxygen, in presence and absence of acids, v. Schulze, J. pr. [2] 21,

Combinations. - 1. With sulphuric and chromic anhydrides, v. Reactions, No. 2 .- 2. With most metallic chlorides; some of the compounds are best regarded as K salts of metal-containing acids, e.g. KAuCl, (v. the different metallic chlor-- 3. With iodine trichloride, to form KCl.ICl,; prepared by mixing KClAq and ICl, Aq, by passing Cl into warm KIAq containing HCl, or by dissolving 1 part KIO₄ in 8 parts HClAq of S.G. 1·176, at 40°-50°. Forms lustrous yellow prisms, smelling of Cl; on heating gives Cl, KCl, and ICl; with water forms KIO₄; ether dissolves out ICl₄ (Filhol, J. Ph. 25, 435, 506).— 4. With iodine monochloride, to form KCl.ICl (Wells a. Wheeler, Am. S. [3] 43, 475).

Potassium, eyanide of; v. vol. ii. p. 346. Potassium, chromicyanide of; chromisulphoeyanide of; and chromocyanide of; v. vol. ii. p.

Potassium, cobalti- and cobalto-cyanide of: v. vol. ii. p. 330.

Potassium, ferrate and ferrite of; v. vol. ii. p. 547.

Potassium, ferri- and ferro-cyanide of; v. vol. ii. pp. 339, 336.

Potassium, fluorides of. Two fluorides are known, KF, and KHF, or KF.HF.

Potassium fluoride KF. Formula probably molecular, from analogy of KI. Prepared by neutralising fIFAq by K.CO, in a dish of Ag or Pt, evaporating to dryness, and heating till HF ceases to be given off. According to Berzelius (P. 2, 218), KF is obtained in crystals by slowly evaporating an aqueous solution at 35°-40° in a very shallow dish. Deliquescent; fusible; solution has alkaline reaction to litmus, and etches glass. Guntz (A. Ch. [6] 3, 5) says KFAq is neutral, but the salt is decomposed in solution and becomes alkaline. Evaporation of a very cone. solution gives KF.2H.O, according to H. Rose. S.G. 2.454 (Bödeker); 2.096 at 21.5° (Clarke, Am. S. [3] 13, 291). Combines with HF to form KF.HF (v. infra); with BF, to form KBF, (v. Potassium borofluoride, vol. i. p. 526); with SiF, to form K2SiF, (v. p. 305); with B2O, to form 2KF.B.O., obtained by dissolving B.O. in molten KF (Schiff, A. 228, 72); with TeF, to form KF.TeF, by evaporating TeO, in HFAq with addition of K.CO. (Högborn, Bl. [2] 35, 60); and with many metallic fluorides.

POTASSIUM-HYDROGEN FLUORIDE KHIF. KF.HF. Prepared by dividing a quantity of HFAq into two equal parts, neutralising one, adding the other, and evaporating; also by evaporating KF in acetic acid. White cubes or four-sided tables; c. sol. water, almost insol. dil. HFAq. When heated gives HF, leaving KF. By electrolysis of HF containing KHF2, F is obtained (v. Fluoring, vol. ii. p. 561). Moissan (C. R. 106, 547) says that two other compounds of KF and HF are obtained by dissolving dry KF in liquid HF, and cooling; to these compounds he gives the formula KF.2HF and KF.3HF. Guntz (A. Ch. [6] 3, 5) gives [HF,KF] = 21,100.

Potassium, haloid compounds of. The compounds KF, KCl, KBr, and KI are the chief halides of K; as KI has been gasified and the molecular weight corresponds with the simplest formula, it is probable that KX expresses the molecular composition of these halides. also exists, but is decomposed by heat; and there are indications of the existence of KBr. KF combines with HF to form KHF, and, according to Moissan, also KF.2HF and KF.3HF.

Potassium, hydride of, K.H. The absorption of H by heated K was observed by Gay-Lussac a. Thénard (A. Ch. 74, 203), and was confirmed by Jacquelain. Troost a. Hautefeuille (A. Ch. [5] 2, 273) found that the absorption of H by K begins at c. 200' and becomes rapid at 350-400°; if the action continues for some time 126 vols. H are absorbed by 1 vol. K. The product is brittle, and much resembles Ag amalgam; it is fusible without change in H or in vacuo; takes fire in contact with air; heated in vacuo, dissociation begins at 200° (for vapourpressures of H given off, v. Dissociation, vol. ii, p. 398). The formula K,H requires 124.6 vols H to 1 vol. K.

Potassium, hydrosulphide of, KHS (Potassium sulphydrate). Gay-Lussac a. Thénard (A. Ch. 115, 165) obtained this compound by heating K in dry H₂S gas; it is more readily formed by heating K₂CO₂ to redness in H₂S (H₂O and CO₂ are given off) (Berzelius, P. 6, 438). By saturating KOHAq with H₂S, and CO₂ are given off) (Columbia) evaporating the conc. solution over CaO or CaCl., in vacuo, Schöne (P. 131, 380) obtained lustrous, rhombohedral crystals of 2KHS.H₂O; and by dehydrating this in a stream of dry H.S. Sabatier (A. Ch. [5] 22, 5) obtained KHS as a yellow, amorphous solid. Prepared in the dry way, KHS appears reddish-black when molten. and white when cold; it crystallises in prisms; is very deliquescent, and reacts strongly alkaline; easily sol. in alcohol. Thomsen (Th. 3, 235) gives [K,S,H,Aq] = 65,140. KHSAq gives off H,S at 70°, according to Drechsel (J. pr. [2] 4, 20). When a current of an ixert gas is passed through KHSAq, H₂S is given off, and K₂SAq remains (Gernez, C. R. 64, 606). Electrolysis produces H and KOH at the negative pole, and H.B at the positive (Bunge, B. 3, 911). KIISAq dissolves S with evolution of H2S; it ppts. MnS, or PbS, from a neutral solution of a Mn or Pb salt, at the same time giving off H2S. These reactions distinguish KHSAq from K2SAq; the · latter does not give off H.S while dissolving S or ppg. MnS or PbS. KHSAq dissolves several sulphides of the less positive metals, e.g. Sb, As, So, forming K thiosalts.

Potassium, hydroxide of, KOH (Caustic potash. Potassium, or potassic, hydrate). S.G. 21 (Dalton); 2044 (Filhol, A. Ch. [3] 21, 415). H.F. [K,O,H] = 103,170; [K,O,H,Aq] = 116,460 (Th. 8, 235).

Konnation.—1. By the reaction between K and H₂O, or K₂O and H₂O, followed by evaporation.—2. By boiling K₂CO₂Aq with CaO.—8. By adding powdered K₂SO₄ to warm conc. BaOAq, evaporating, filtering, and again evaporating (Schubert, J. pr. 26, 117).—4. By heating KNO, with 2-8 parts thin copper turnings, to redness, in an iron, or copper, crucible, extracting with water when cold, filtering from CuO and Ou₂O₄ and evaporating (Wöhler, A. 87, 373).—5. By heating I part KNO₃ with 1 part Fe₂O₃, in a closed crucible of Cu, H being passed in; treating with water, and drawing off the clear liquid, and evaporating it (Schulze, Z. 1861. 109). Evaporation of KOHAq should be performed in vessels of polished iron, or, better, of silver.

Preparation.—1. A solution of pure K_CO₂ in 10-12 parts water is boiled, in a dish of silver or polished iron, with milk of lime, added little by little, till a portion of the clear supernatant liquid gives no effervescence with an acid; rather more than half as much CaO is required as the weight of K_CO₂ taken; large excess of CaO should be avoided; water should be added as the boiling proceeds, because if the quantity of water is less than c. 10 times the quantity of K_CO₂ used the KOHAq begins to decompose the CaCO₂ formed, and the change of K_CO₂ to KOH stops (Liebig, A. 1, 124). When the change is completed, the vessel is closed, and, after a few hours, the clear liquid is drawn off by a syphon; the liquid is then rapidly evaporated in an iron vessel, allowed to stand for an hour or two, the vessel being closed, syphoned off from anypp, that has formed.

evaporated in a silver dish till the oily liquid thus produced begins to volatilise in white clouds, and cooled in an exsiccator. Impure KOH may be freed from all impurities, except KCl and traces of K₂CO₂ and KC₂H₁O₂, by dissolving in absolute alcohol, allowing to settle, draining off, and evaporating, at first on a water-bath, in a silver dish; the resinous matter which is produced is removed from the warm evaporated semi-solid mass, by a silver spatula, and the KOH is then poured out on to a plate of polished iron, or, better, of silver.

Graeger (J. pr. 96, 188) recommends to heat the K₂CO₂Aq used with Ag₂CO₃, to filter from AgCl and excess of Ag₂CO₃, to boil, in a silver dish, with pure CaO made by strongly heating pure CaCO₃, to filter the solution of KOH through pounded marble which has been washed with water till free from very fine particles, and to evaporate in a silver dish.—2. Water and benzene are placed in a silver dish, and small pieces of K, cut from the inside of a lump, are thrown in one by one; the K remains near the surface of separation of the two liquids, and reacts fairly slowly with the water. The benzene is removed by warming, and the aqueous solution of KOH is then evaporated to dryness.

Properties .- After fusion, KOH is a white. hard, brittle solid, often showing a fibrous texture. Melts below red heat, and volatilises at full redness in white pungent vapour. Very deliquescent; sol. water with production of much heat, [KOH,Aq] = 13,290 (Th. 3, 235). Easily sol. alcohol. Skey (C. N. 36, 48) says KOH is very sl. sol. ether. Absorbs CO, rapidly from the air, forming KHCO₃. KOH has a slight, but nauseous, odour, a strongly acrid taste, and acts as a powerful cautery towards both animal and vegetable matter. KOHAq should be kept in glass vessels free from Pb, as it corrodes lead-glass; it attacks vessels of glass or porcelain when heated in them. To keep KOHAq free from carbonate, it is advisable to store it in bottles fitted with corks carrying a syphon-tube, and a rather wide tube filled with a mixture c. equal parts CaO and Na2SO4, well rubbed together, dried over a flame, and passed through a sieve to remove fine powder; the air which enters through this mirture is quite free from

KOHAq is strongly alkaline; the affinity of KOH in solution is large, about equal to that of NaOH and LiOH, and about 50 times greater than NH₃Aq (Ostwald). KOH saponifies ethereal salts, and ppts. most of the heavier metals as oxides or hydroxides from solutions of their

The table on next page, given by Lunge, shows the composition of KOHAq of different S.G.

Expansion occurs when conc. KOHAq is diluted; Frankenheim (J. 1847-8. 69) gives $V=1+\cdot 000415t+\cdot 000000577t^2$ as representing the volume of KOHAq S.G. 1-2738 at 0°, between 18° and 100°.

Reactions.—1. According to Deville (C. R. 45, 857), KOH is decomposed to K. Q. and H. by heating to white heat.—2. Strongly heated with non-volatile acidic anhydrides, water and potassium, laits are formed,—8. Heated with potassium, K.O and H. are formed; heated with sodium under a liquid free from Q, an alloy of K and Na

Is said to be formed (Williams, Rep. Chim. pure, evaporatir 3,177).—4. Iron decomposes KOH at white heat, and evaporating Fe₂O₂, H, and K.—5. Molten KOH acts formed by generally as an oxidiser: e.g. Fe, As, Sb, Pt, &c. is decompored form ferrate, arsenate, antimonate, and platinate of K; Or,O₂ forms K,OrO,, &c. Salts are generally decomposed by molten KOH, giving 121, 225).

K salts, and setting free the bases.—6. KOHAq neutralises acids, forming salts.—7. KOHAq decomposes most metallic salts in solution, ppg. oxides or hydroxides of the metals.—8. According to Schöne (A. 193, 241), addition of hydrogen peroxide to KOHAq produces K₂O₄ (v. Potassium tetroxide, p. 305).

Combinations.—1. With carbon dioxide, to form KHCO₂.—2. With water, to form hydrates.

TETROXIDE, p. 305).

Combinations.—1. With carbon dioxide, to form KHCO,—2. With water, to form hydrates. Pickering (C. J. 63, 890) obtained KOH.H.O freezing at 143°, KOH.2H.O freezing at 35.5°, and KOH.4H.O freezing —32.7° (cf. Walter, P. 39, 192; Schöne, P. 131, 147). P. (l.c.) gives full data for freezing points of KOHAq. Göttig (B. 20, 1094) described two hydrates, 2KOH.9H.O and 2KOH.5H.O, obtained from an alcoholic solution of KOH containing some water; but in a later paper (B. 20, 1907) G. says that these hydrates contained alcohol besides water.

3. With methyl alcohol, to form 3KOH.5MeOH (Göttig, B. 20, 1832). 4. With ethylic alcohol, to form KOH.2EtOH (Engel, C. R. 103, 155); decomposed by heating to EtOK, EtOH, and 11.O.

Patassium, iddides of Two icidias are

Potassium, iodides of. Two iodides are known, KI and KI.

Potassium ionne, Kl. Mol. w. 165-57. Melts at 634° (Carnelley, C. J. 33, 279). S.G. 3-659 (Playfair a. Joule, C. S. Mon. 2, 401); 3-077 to 3-081 (Schröder, P. 106, 226); fused 2-497 (Quincke, P. 138, 141); v. also Spring (B. 16, 2724). V.D. 91-5 (Dewar a. Scott, Pr. 29, 206); 84-6 at above 1300°, in N (Mensching a. Meyer, Z. P. C. 1, 157). S.H. (20° to 99°) -08191 (Regnault, A. Ch. [3] J. 129). Vol. at 40° evol. at 0° (1 + 20012796) (Fizeau, C. R. 64, 314). S. 132-1 at 5°, 136-1 at 10°, 140-2 at 15°, 144-2 at 20°, 152-3 at 39°, 169 at 40°, 168 at 50°, 176 at 60°, 184 at 70°, 193 at 80°, 201 at 90°, 209 at 100°, 218 at 110° (Mulder, Scheikund. Verhandel, Rotterdam, 1864.162). Coppet (A. Ch. [5] 30, 411) gives S. at t° = 126-23 + 8088t, where t varies from -5°9° to 120°. S. in aqueous alcohol is given in following table. (Gerardin, A. Ch. [4] 5, 139); the values hold for 0° to 18°;

		-8322	6.2

H.F. [K,I] = 80,130; $[K,I,\Lambda q] = 75,020$ (Th. 3, 235).

Formation.—1. By the direct union of K and I.—2. By neutralising HIAq by K₂CO₃, and evaporating.—3. I is added to water and iron fillings till the iron is almost wholly dissolved, the solution is filtered, and K₂CO₃ added so long as FeCO₃ ppts.; the liquid is filtered (if alkaline it is neutralised by Hi Aq) and evaporated, any FeO₃ which separates being filtered off (Baup, J. Ph. 9, 37, 122).—4. By adding I to KOHAq, evaporating, heating with C, dissolving, filtering, and evaporating (v. Preparation).—5. Bal, Aq is formed by the action of I and water on BaS, and is decomposed by K,SO₄; BaSO₄ is filtered off, and the liquid is evaporated. Liebig (A. 121, 222) used Cal₂ in place of Bal₄ (cf. Pettenkoler, A. 121, 225).

Preparation. -- Moderately, but not too, conc. KOHAq, quite free from K,CO,, is prepared from K.CO.Aq and CaO (v. Potassium Hydroxide, Preparation, p. 802); I is added, little by little, to the slightly warm liquid till a slight yellow colour is produced; very finely powdered charcoal is now added, equal to c. $\frac{1}{10}$ of the weight of I used, the liquid is evaporated quite to dryness, the residue is powdered, and heated, in a closed crucible, to dull redness for some time $(6KOHAq + 6I = 5KIAq + KIO_3Aq + 3H_2O)$; $KIO_s + 3C = KI + 3CO$). The contents of the crucible, when cold, are extracted with water, the liquid is filtered, neutralised by HIAq if alkaline, and crystallised. Morse a. Burton (Am. 10, 321) recommend to remove traces of KIO, by boiling for some time with Zn amalgam and water, filtering, and crystallising; neither Zn nor Hg is found in the filtrate. The Zn amalgam is made by agitating zinc-dust with Hg in presence of tartaric acid solution, and washing with water.

Properties .- White cubes; non-deliquescent. Has a sharp taste. Solution in water is attended with fall of temperature; 140 pts. in 100 pts. water at 10.8° produce a fall to -11.7° (Rüdorff,

P. 136, 276).

Reactions .- 1. Unchanged in dry air, but decomposed in ordinary air when exposed to sunlight (v. Downes a. Blunt, Pr. 29, 319; Loew. Fr. 1870. 251). Air containing ozone also decomposes KI (Houzeau, J. 1858, 60), -2, Heated in air to 230°, some KIOa is formed. -3. Heated in steam, I is evolved (Petterson, Fr. 1870. 362) and HIAq formed (Schindler, Mag. Pharm. 31, 33) .- 4. Decomposed, with separation of I, and formation of KOH, by heating with lead dioxide, manganese dioxide, arsenic oxide, antimonic oxide, chromium trioxide, hydrogen peroxide, &o. (v. Weltzien, A. 138, 134).—5. Chlorine decomposes hot KI to KCl and I. KIAq with ClAq gives KClAq, and I; with excess of Cl, ICl, is formed and remains in solution, or combines with the KCl and separates as KCl.ICl₃, according to the quantity of water present. Bromine acts similarly to Cl.—6. Nitrous acid solution sets I free; KNO, and dil. HClAq act in the same way (v. Price, C. J. 4, 155) .- 7. Conc. sulphuric acid, or nitric acid, decomposes KI when heated with it, giving sulphate or nitrate of K, and I; with H.SO, SO, and H.S are also formed. Addition of cone. H.SO, to KIAq, or evaporation with HNO, Aq, sets I free. If KIAq contains KIO, a few drops of a dilute acid suffice to give free I (5H1Aq + HIO, Aq = 3I2 + 3H.O). Aqua regia sets I free from KIAq (for the delicacy of this reaction v. Harting, J. pr. 22, 46).—8. Heated with sulphuric anhydride, K,SO,, SO2, and I are formed (H. Rose, 38, 121).—9. Manganese dioxide and sulphuric acid produce I, MnSO,, and K₂SO, when heated with KI.—10. KI fused with potassium-hydrogen sulphate gives K,SO, and I.—11. Fusion with potassium chlorate produces KIO,—12. Heating with barium mitrate forms KIO, and BaO, (Henry, J. Ph. 18, 845) .- 13. By heating with ammonium chloride, I, AmI, and KCl are formed.-14. Conc. potassium ferricyanide solution gives I and K.FeCy, Aq; on dilution the action is reversed (Mohr, A. 105, 57).—15. Heated with potassium borate, KIO, and a polyborate (? probably K.B.O. are formed (Schiff, A. 228, 72).

Combinations .- 1. With most iodiles of less positive metals (v. various metallic iodides). Several of the compounds produced are best regarded as K salts of metal-containing acids (v. Remsen, Am. 11, No. 5).—2. With arsenious oxide to form KI.As.O. (Schiff, A. 228, 72).—3. With potassium ferricyanide, to form a very unstable compound, KI.K, FeCy, (Preuss, A. 29, 323; Mohr, A. 105, 57; Blomstrand, J. pr. [2] 3, 207; Kern, C. N. 33, 184).

Potassium trit-iodide KI, Dark-blue, lustrous needles; almost black by reflected light; melts at 45°; S.G. 3 498 at c. 15°; by saturating KIAq with I, and evaporating over H₂SO₄ (Johnson, C. J. 31, 249). Very deliquescent; in a little water some I is deposited; sol. alcohol, in a very small quantity water, and in saturated solution of I in KIAq. Agitation with CS, of conc. KIAq saturated with I abstracts the dissolved I (Baudrimont, C. R. 51, 827). Jörgensen (J. pr., [2] 2, 317) found, however, that CS₂ did not remove the I from an alcoholic solution of KI containing excess of I in ratio KI:2I, and that alcoholic KI completely decolourised solutions of I in CS...

Potassium di-fodide ?KI. A solution of 3 pts. I in 4 pts. KI in water is said by Guyard (Bl. [2] 31, 297) to contain an unstable compound of this composition; with Pb(NO₃) Aq or Pb(C2H,O2) Aq, this solution gives an almost

black pp., said by G. to be PbI,

Potassium, iodobromide of. The compound KBr.IBr may be called iodobromide of potassium: v. Potassium bromide, Combinations, p. 300.

Potassium, iodochlorides of. The compounds KCl.ICl, and KCl.ICl may be called iodochlorides of potassium; v. Potassium chloride, Combinations Nos. 3 and 4, p. 301.

Potassium, iridicyanide of; v. vol. ii. p.

Potassium mangani- and mangano-cyanide of; v. vol. ii. p. 342.

Potassium, nitride of, K.N. Formed by heating to redness KNH₂ (v. Potassium amide, p. 209) in absence of O. A dark-grey, almost black, solid. Sublimes partially at white heat. Takes fire in air, with evolution of N; reacts with water to give KOHAq and NH. K, N is a conductor of electricity. Combines with S and P (Gay-Lussac a. Thénard, A. Ch. 65, 325).

Potassium, nitroprusside of; v. vol. ii. p.

Potassium, osmocyanide of; v. vol. ii. p.

Potassium, oxides of. Two oxides have been certainly isolated, K2O and K2O4; there are indications of the existence of others.

POTASSIUM OXIDE K₂O (Potassium monoxide). A mixture of K₂O and K₂O₁ is formed by burning K in air; when K is burnt in a stream of dry O only K₂O, is produced, but on strongly heating this product O is given off, and K.O remains (Davy, T. 1808 [1] 5). K.O is also formed by heating KOH and K in the ratio KOH: K; according to Beketoff (Bl. [2] 87, 491), K and KOH do not react. B. says that K₂O may be prepared by heating a mixture of K₂O, and K in a silver dish. To prepare pure K₂O Kühnemann (C. C. 1864. 491) recommends to lead air, freed from CO, over K heated just to fusion; the K spreads out into a thin layer

lustrous solid; S.G. 2.656 (Karsten, S. 65, 894); melts at full red-heat, and volatilises at a very high temperature. Thomsen (Th. 8, 235) gives [K', 0, Aq] = 165,460. K.O reacts with water to form KOHAq, with production of much heat. Von Schaffgotsch (A. 43, 17) says that K.O.Fe.O, is obtained, but not pure, by heating Fe,O, with K,CO,.

POTASSIUM TETROXIDE K2O4 (Potassium peroxide). The formation of this compound by heating K in dry air or O was observed by Gay-Lussac a. Thénard (A. Ch. 65, 325). The preparation and properties of the compound were examined by Vernon Harcourt (C. J. 14, 267). Prepared by heating K till it melts, in a hard glass flask filled with N, then sending in a slow stream of dry air, and continuing to heat in the air-stream until the metal is completely changed to a yellowish amorphous solid, and heating this for some time in dry O. It is also formed by throwing small pieces of K into molten KNO, (Bolton, C. N. 52, 289). A mixture of K.O. with KOH.H.O is said to be formed by mixing equivalents of KOH and H.O. in Aq, and evaporating in vacuo (Schöne, A. 193, 241). K.O. is an amorphous powder, having the colour of PbCrO. It begins to soften at 280°, and melts at red heat to a black liquid, which crystallises in leaflets on cooling. At white heat gives off O and leaves K.O. Deliquesces in moist air, giving off O. In water forms KOHAq and H.O.Aq, and evolves O. Heated in H produces KOH and H₂O. K₂O, oxidises P, S, C, &c., and many metals to their highest oxides. Reacts with CO, when heated, giving K₂CO₃ and O. No action with N₂O; with NO forms KNO₂ and KNO, and gives off N oxides.

Oxides of Potassium other than K.O and K2O4. Harcourt (l.c.) asserted the existence of K₂O₂, obtained by exidation of K. Lupton (C. J. 1876, [2] 565) thought that the exides K₂O₃, K₄O₃, and K₀O, are formed by the action of air on K at c. 65°; these oxides may be regarded, according to L., as 3K2O.K2O2, K2O.K2O2, and 2K2O.K2O2 respectively. The substance described as a suboxide, K,O, is said by L. to be a mixture of K and K_2O . Schöne (A. 193, 241) obtained $K_2H_1O_4$, probably $K_2O_2:2\Pi_2O_2$, by evaporating, in vacuo, at -10° , a mixture of 1 equiv. KOH and 2 equivs. H.O. in Aq.

Potassium, phosphide of. K and P combine when heated under rock-oil, or in N, forming a dark-yellow solid (Magnus, P. 17, 517; Vigier, A. 122, 831). A compound, or compounds, of K and P seems also to be formed when K is heated in PH, and also when K is heated in P in a stream of H (H. Rose, P. 12, 547). The compound prepared by Rose was a crystalline, red-dish, lustrous solid; decomposed by water, giving KH₂PO₂Aq and PH₃, and when heated in air, to K phosphate. burning,

Potassium, platinocyanide of, and allied salts; v. vol. ii. pp. 844-5.

Potassium, salts of. Compounds formed by replacing H of acids by K. The chief salts of K, besides the halides and sulphides, are carbonates, chlorate and perchlorate, chromate and derivatives, iodate and periodates, nitrate and nitrite, phosphates and derivatives, silicates, Vol. IV, sulphates and derivatives, sulphite, thiosulphate (v. Carbonates, Phosphates, &c.).

Potassium, selenides of. Berzelius (Lehr-buch, 5th ed. 2, 222) investigated the conditions of combination of K and Se, without isolating and analysing any definite compounds. Se and K combine when melted together: a steel-grey solid sublimes, which dissolves in water with formation of a red liquid that decomposes in air with separation of Se, and gives off H.Se with acids. . Compounds of Se and K are also formed by reducing K.SeO, or K.SeO, by C or H at red heat (Wöhler a. Dean, A. 97, 5; Rathke, A. 152, 211). Mixtures of selenate and selenides of K are formed by fusing KOH or K, CO, with Se. Boiling KOHAq dissolves So, forming a brown liquid, from which a brown powder separates on evaporation, and which gives Se when heated with acids, or when diluted and allowed to stand in air.

Fabre (C. R. 102, 613) obtained K. Se. xH. O. x = 9, 14, and 19, by passing a rapid current of H2Se into KOHAq of different concentrations these hydrates of potassium monoselenide are all very easily decomposed. Fabre (C. R. 102, 703) gives the following thermal data: [K*,Se] = 98,340 from solid elements; [2KOHAq,H_SeAq] = 7,520; $[2KOHAq, H_2Se] = 16,920$; [K'Se, Aq] = 8,540.

Potassium, selenocyanide of, v. vol. ii. p. 848. Potassium, selenostannate of, K.SuSe, Saq. Yellow, unstable crystals; by saturating K. SeAq with SnSe, and evaporating in vacuo (Ditte. C. R. 95, 641).

Potassium, selenothiostannate of.

K.SnSe,S 3aq. Yellow, octahedral crystals; by boiling K,SAq with Sn and Sc, and evaporating in vacuo. Sol. water, with red colour. Both solid and solution in water very readily undergo decomposition, with separation of Se (Ditte, l.c.).

Potassium, silicide of. By reducing S.O. by K, Berzelius obtained a brown solid, which reacted with water to give H, KOHAq, and SiO,

(Lehrbuch, 5th ed. 2, 84).

Potassium, silicofluoride of, K,SiF. Prepared by adding H2SiF4Aq to a fairly conc. solution of a K salt, washing, and drying. Small tesseral white crystals. Preis (Listy Chem. 13, 150; abstract in C. J. 58, 694) found hexagonal, and also regular, crystals of this salt, along with CaSO,, in a basin wherein phosphoric acid had been prepared from phosphorite. K.SiF. is isodimorphous with the ammonium salt. 2.665 at 17.5° (Stolba, J. pr. 97, 503). Easily sol. hot water, very sl. sol. cold water. Melts at low red heat, giving off SiF, and leaving KF (v. Bothe, Hofman's Ber. über die Entwick. der Chem. Industric, 1, 318). Decomposed by conc. H.SO., giving off SiF, and HF. Decomposed by boiling (not cold) solutions of alkali hydroxides or carbonates, with separation of gelatinous silicic acid and formation of KF.

Potassium, siliconitride of. The white, infusible solid, obtained by heating SiO₂ with KCN, is probably a compound of K, Si, and N

(Balmain, P. M. October 1842).

Potassium, sulphides of. K and S combine when heated together, the K burning brilliantly. Five compounds of K and S are known: K,S, K₂S₂, K₂S₃, K₄S₄, and K₂S₅. They are all sol. water, the polysulphides also in alcohol. K₂SAq is colourless; solutions of the others are coloured

yellowish brown, the colour being deeper the greater the proportion of S. Solutions are decomposed by acids; K,SAq with evolution of H,S, the other solutions also with ppn. of S. Solusale other solutions also with plin. of S. Solutions decompose in air; K.SAq to K.S.Q.Aq and KOHAq, K.S.Aq to K.S.Q.Aq, and the others to K.S.Q.Aq with separation of S. Solutions of the polysulphides react with K2SO, Aq to form K2SAq and K,S,O,Aq; these solutions are reduced to K,SAq by shaking with Hg. With EtI or EtBr they form Et, S,, which dissolves the S set free; these solutions dialyse unchanged (Spring a. Demarteau, Bl. [3] 1, 311).

POTASSIUM MONOSULPHIDE K2S. Formed by reducing dry K2SO4; by heating in H (Berzelius, P. 6, 438); by heating with C (Berthier, A. Ch. 22, 233; Bauer, J. pr. 75, 246; Wittstock, P. 55, 536). Not obtained free from polysulphides by these methods; if vessels of glass or porcelain are used the product contains SiO2, as K.S acts on silicates. The product of the foregoing reactions is a brown, crystalline, deliquescent solid; sol. in water, with production of much heat and formation of KSHAq and KOHAq; Thomsen (Th. 3, 235) gives [K*,S,Aq] = 113,300.
Sabatier (A. Ch. [5] 22, 5) says that K.S has never been obtained pure. An aqueous solution of K2S is prepared by saturating KOHAq with H2S, and adding an equal quantity of the same KOHAq. By evaporating this solution in vacuo at a low temperature, the pentahydrate K,S.5H,O is obtained in orthorhombic crystals, which lose 3H,O by heating to 150°, out of air (Schöne, P. 181, 380; cf. Sabatier, l.c.). K2SAq is colourless out of contact with air; it is very alkaline and caustic; in air it becomes yellow, H₂S is given off, and K₂CO₂Aq and K₂S₂O₃Aq are formed. K₂SAq dissolves S, forming polysulphides: it

dissolves Fe or Fe₂O₃, forming a green liquid.

Porassium disclination K₂S₂. Formed by allowing an alcoholic solution of K₂S to stand in air till the surface is covered with a film of K2S2O2, then pouring off, and evaporating in racuo (Berzelius, l.c.). Also by heating 2 equiva-lents KHSO, with 7 or more equivalents C (Geiger). Berzelius obtained K₂S₂ by heating 4 equivalents K2CO3 with rather less than 7 equivalents S. A yellowish red, deliquescent solid; K₂S₂Aq is yellow; in air it oxidises to K₂S₂O₂Aq without separation of S; acids give off H₂S and cause ppn. of S.

POTASSIUM TRISULPHIDE K,S. Formed by Potassium Trisurphide A.S., Formed by passing CS, over K.CO, heated to redness (Berzelius, Lc.; cf. Schöne, Lc.). Also by heating 100 parts K.CO, with 58-22 parts S to dull redness, till CO, ceases to be given off; the product contains some K.SO,. Also, with some S, by passing H.S over strongly-heated K.SO. By heating K.S. to over 800°. A yellowish-brown solid, black when molten; not decomposed at 900°, gives off S at white heat (B.). Easily sol. water and alcohol; K,S,Aq in air gives K,S,O,Aq with separation of S; decomposed by acids, S separating and H.S being evolved.

POTASSIUM TETRASULPHIDE K₂S₄. Formed by passing CS₂ over strongly-heated K₂SO₄ so long as CO, is produced. Also by melting K.CO, with 1 to 2 parts S, heating till excess of S is removed, and then reducing K₂SO, formed by heating in H₂S. A red-brown, crystalline solid (B., Lc.; S., Lc.). Decomposed at 600°-900° to K₂S₂ and S.

The dihydrate K.S., 2H.O is obtained by bound K,SAq with the proper quantity of S, and evapo rating in vacuo (S., l.c.). Sabatier (A. Ch. [5] 22, 53) obtained the octahydrate, K.S., SH.O. by adding 90 p.c. alcohol to K,S,Aq, separating the brown oily liquid, and letting it crystallise.

POTASSIUM PENTASULPHIDE K.S. Formed by heating any of the lower sulphides with S until the excess is removed; Schöne (L.c.) says temperature should not exceed 600° (p. B., Lc.). A solution of K.S., containing also K.S.O., is formed by heating K.CO.Aq with S (Fordos a. Gélis, C. R. 23, 211); or by digesting a solution of a lower sulphide with S (B., l.c.). A red, fusible solid; decomposed by heating in steam, giving K,SO, and H.S (Drechsel, J. pr. [2] 4, 20). Very sol. water, also in alcohol; K,SA, 4 slowly decomposes in air, giving K,SO,AA, K,CO,AA, and S; acids evolve H,S and separate S.

Liver of sulphur. This name is given to the brown solid obtained by heating S with K₂CO₃ in a closed vessel; it contains various sulphides of K, along with K₂SO₄, and generally some K, CO,.

Potassium, sulphydrate of: v. Potassium нудковицениры, р. 302.

Potassium, sulphocyanide of; v. vol. ii. pp.

Potassium, telluride of. Probably K.Te. By heating together K and To in H; also by heating a mixture of 100 pts. H,TeO₃, 20 pts. KOH, and 10 pts. C. A brittle, crystalline, copper-coloured solid. Easily sol. water; exposed to air Te separates from the solution. HClAq evolves H₂Te (Davy; v. also Berzelius, Lehrbuch (5th ed.) 2, 247).

Potassium, tellurofluoride of, KF.TeF.; v. POTASSIUM FLUORIDE, p. 301.

Potassium, thio-arsenates and thio-arsenites

of; v. vol. i. pp. 317, 316.

Potassium, thiocarbonate of; v. vol. i. p. M. M. P. M.

PRASEODYMIUM. The constituent of didymium which yields green-coloured salts; v. DIDYMIUM, vol. ii. p. 383.

PREHNITENE v. c-DURENE.

PREHNITIC ACID C, H,O, i.e. C_aH₂(CO₂H)₄[1:2:8:4]. Mol. w. 254. [237°-250°]. Formed by heating either of the tetrahydrides of pyromellitic acid with H₂SO₄ (Baeyer, A. 166, 325), and by the oxidation of c-durene and of c-tetra-ethyl-benzene (Töhl, B. 21, 907; Galle, B. 16, 1746; Jacobsen, B. 17, 2518). Crystallises from water in large prisms (containing 2aq) resembling the mineral prehnite. Converted by fusion into an anhydride C₁₀H₄O, [239°]. May be reduced to a viscid hydride. - KH, A'raq. -BaH,A,' 3aq. -BaH,A' aq: needles. -Pb,A': small needles, insol. water.

Methyl ether Me, A'v. [104°-108°]. PREHNITOL v. c-DurenoL.

PREHNOMALIC ACID C, H,O, i.e.

C.H.,(OH)(CO.H)₄. Oxy-prehnitic acid dihydride. [210°]. A product of the action of H.SO, on the tetrahydrides of mellitic acid (Baeyer, A. 166, 325; B. 4, 275). Needles, readily converted by heat into an anhydride CaH, O1, [210°]. heating with H₂SO₂, or by treatment with B_r, it is converted into prehnitic acid.—Ag, A^r.

PRIMULA CAMPHOR O₁₁H₁₇O₂. [49°].

(above 200°). Contained in the root of Primula

veris (Mutschler, A. 185, 222). Six-sided plates, v. sl. sol. water, v. sol. alcohol and ether. Smells like anise. FeCl, colours its aqueous solution violet. Fields salicylic acid on oxidation.

PRIMULINE BASE $C_{:s}H_{1s}N_{1}S_{1}$ i.e. $-C_{s}H_{1s}N_{s}S_{2}$ O.O. $H_{s}N_{s}S_{s}$ O.O. $H_{s}N_{s}S_{s}$

Prepared by heating p-toluidine (2 mols.) with sulphur (4 or 5 atoms), H.S being evolved (Green, C. J. 55, 234). Yellowish powder, nearly insol. all solvents. Not decomposed at 400°. Its salts are decomposed by water. The Na salt of its sulphonic acid (primuline), is taken up by unmordanted cotton. KOH at 260° yields amidotolyl-mercaptan and p-amido-benzoic acid (Gattermann, B. 22, 425, 1066).

Dehydrothiotoluidine C1, H12SN2 i.e.

 $C_eH_aMe < S C.C_eH_4.NH_2.$ [191°]. (434° at 766 mm.) (Pfitzinger a. Gattermann, B. 22, 1066). An intermediate body in the preparation of primuline. Formed, together with primuline base, by heating p-toluidine with S (Dahl & Co., G. P. 35790; Green, C. J. 55, 230). Got also by the action of HI and P upon primuline (Jacobsen, B. 22, 330). Yellowish iridescent needles (from isoamyl alcohol), v. sol. HOAc, sl. sol. hot alcohol, v. sl. sol. benzene, almost insol. boiling water. Its alcoholic solutions have violet-blue fluorescence. Ppd. by adding water to its solution in HClAq.

Reactions.—1. Yields p-toluidine on distilla-

tion with zinc-dust. - 2. Yields primuline on heating with S. - 3. Converted by diazotisation in

boiling alcoholic solution into $C_uH_xMe < \frac{N}{S} > CPh$

[123°] .- 4. When diazotised and boiled with water it gives C, H, (OH)N, S [256°], which gives C, H, (OAc)N, S [132°], -5. Furning H, SO, (containing 70 p.c. SO,) forms, below 50°, a sulphonic acid C14H11(SO3H)SN2, which crystallises in yellow needles (containing aq), or orange plates (containing 2aq), sl. sol. hot water, and forms NH, A'aq, sl. sol, hot water, CuA', 2nq, a reddishbrown pp., and AgA', a white pp.—6. MeI yields C, H₁₀(NMe₂)NS [197°] (434°), and C_{1.}H₁₀(NMe,I)NS, a bright-yellow powder, v. sol. water. MeOH and HCl at 150°-200° give O₁₄H₁₀(NMe,Cl)NS, a yellow powder which forms (C₁,H₁₀NS,NMe,Cl),PtCl₄ [234°].

Acetyl derivative C, H, AcN, S. [227°]. White plates or prisms, sl. sol. HOAc.

PROPACONIC ACID v. Lactone of Oxy-BUTYLMALEÏC ACID.

PROPANE C3H8 i.e. CH3.CH2.CH3. Mol. w. 44. (-17°). S. (alcohol) 6. H.F.p. 35,110. H.F.v. 33,870 (Thomsen, Th. 4, 52). Occurs in the gases given off from the petroleum springs of the United States (Ronalds, C. J. 18,54; Lefevre, Z. [2] 5, 185). Formed by the action of HI on propyl iodide, allyl iodide, isopropyl iodide, acetone, and glycerin (Berthelot, Bl. 7, 60; 9, 18, 184). Prepared by heating n-propyl iodide (9.6 pts.) with AlCl. (2.5 pts.) at 140° (Köhnlein, B. 16, 560), or by heating isopropyl iodide with zinc and HClAq (Schorlemmer, A. 150, 209). Gas. On compression with water at a low temperature it yields a hydrate, dissociating at 8.5° (Villard, C. R. 111, 302).

References, DI-BROMO-, BROMO-10DO-, BROMO-

MITBO-, CHLORO-, CHLORO-IODO-, DI-GHLORO-MITRO-, Dr. 1000, and NITRO- PROPANE.

PROPANE CARBOXYLIC ACID v. BUTTER ACID.

Propane dicarboxylic acid v. GLUTARIC-PYROTARIARIC, and ETHYL-MALONIC ACIDS.

Propane tricarboxylic acid CaH,Os i.e CH,CH(CO,H).CH(CO,H), (Bischoff, B. 18, 2164; 14, 614; 15, 1107; 17, 2783; 22, 8180; A. 214, 53). [146°]. Formed by saponitying the ether with dilute alcoholic potash. Crystalline mass, v. e. sol. water, alcohol, and ether. Splits up when heated alone, or with dilute HClAq, into CO2 and pyrotartaric acid. Bromina forms bromopyrotartaric and bromocrotonic acids.—Ba, A"; bulky pp. $ds.-Ba_aA'''_a$: bulky pp. $Methyl\cdot di\cdot ethyl$ is ther MeEt,A'''. (266°).

S.G. 4 1.078. Formed from methyl a-chloro-

propionate and sodium malonic ether. $Ethyl \ eth \ r \ Et, A'''$. (270·3° cor.). S.G. 2° 1·0698. $\mu_D = 1.4288$ at 20°. Formed from sodium malonic other and a-bromo-propionic ether. Oil, miscible with alsohol and ether. NaOEt yields C,H,Na(CO,Na)(CO,Et).

Propane tricarboxylic acid

CH, C(CO,H), CH, CO,H.

Methyl ether Me₂A'''. Oil (Barthe). Ethyl ether Et, A'''. (273.5° oor.). S.G. Ψ 1 077. $\mu_D = 1.4311$ at 20°. Formed from sodium

methyl-malonic ether and hloro-acetic ether, and also from sodium ethane tricarboxylic ether and MeI or MeCl (Bischoff a. Von Kuhlberg, B. 23, 635). Yields on saponification pyrotartaric and a little succinic acid.

and a little succinic acid.

Methyl ether of the mono-nitrile
CH_xC(CN)(CO_xMe).CH_xCO_xMe. Formed from
metnyl cyanosuccinate, MeOH, and MeI
at 70° (Barthe, Bl. [3] 1, 303; C. R. 108,
297; 112, 1013). Oil. The corresponding
CII_xC(CN)(CO_xEt).CH_xCO_xEt is also an oil (185°
at 35 mu. at 35 mm.).

Propane tricarboxylic acid

CO.H.CH.CH.CH(CO.H)... Ethylether Et.A". (161° at 13 mm.). S.G. 20 1.0808. Formed from sodium malonic ether and \$\beta\$-bromo-propionic ether (Emery, \$B\$. 24, 282). The free acid splits up into CO, and

glutaric acid on boiling with HClAq. Isomeride v. TRICARBALLYLIC ACID. Propane tetracarboxylic acid

CO.H.CH...CH(CO.H).CH(CO.H). Ethylether Et.A. (204° at 18 mm.). S.G. ²⁰ 1·1184. Formed from sodium malonic ether and chloro-succinic ether (Emery, B. 28, 8759).
Oil, v. sol. alcohol and ether. The free acid splits up into CO, and tricarballylic acid.

Propane tetracarboxylic acid (CO,H),CH.CH,CH(CO,H)2. Dicarboxy-glutaric acid. [170°]. An acid formed by the action of sodium amalgam on dicarboxyglutaconic ether C.H.Et.O. in alkaline solution (Conrad a. Guthzeit, A. 222, 257). One of the products of the action of chloro-di-methyl oxide on sod um malonic ether (Kleber, A. 246, 106). Got also by boiling its ether with dilute alcoholic potash (Guthzeit a. Dressel, B. 21, 2234; 22, 1423; A. 256, 174). Crystalline powder (from ether), v. e. sol. water. At 180° it splits up into CO, and glutaric acid [98°].—Ba,A'' 2aq.—Ca,A'' 2aq.—Pb,A'' 2aq.

Ethyl ether Et.A'r. (235° at 80 mm.).

Control (Extraversion Courts)

8.G. 22 1-116. Formed from sodium malonio ether by treatment with CH_cCl₂ or CH_cI₃, and got also by reducing dicarboxy-glutaconic ether with zinc-dust and HOAo (W. H. Perkin, jun., C. J. 59, 993). Oil, with very bitter taste. NaOEt forms a di-sodium derivative, which reacts with EtI forming oily C₁,H₂₈O₈ (c. 248° in sacuo).

Propyl-tri-ethyl ether Et, PrA'. (195°-202° at 15 mm.). Formed from propyl triethyl dicarboxy-glutaconate, zinc-dust, and HOAc.

Colourless oil.

Propane tetracarboxylic acid

CO.H.CH. C(CO.H).r.CH. CO.H. [151°]. Got by saponifying its ether with alcoholic potash. Prisms (from water), v. sol. water, alcohol, and ether. At 170° it splits up into CO. and tricarballylic acid.—K.,HA!" 2½ aq (at 100°).—Zn.A!" 3aq (dried at 100°).—Pb.A!" aq.—Ag.A": include pp. Ethyl ether Et.A!". (295° uncor.). S.G.

Ethyl ether Et.A'. (295° uncor.). S.G. 44 1-102. Formed from malonic ether, alcoholic NaOEt, and chforo-acetic ether, followed by a second dose of NaOEt and chloro-acetic ether (Bischoff, B. 13, 2163; A. 214, 61). Oil.

Ethyl ether of the mono-nitrile CO_Et.CH_.C(CN)(CO_Et).CH_.CO_Et. [41°]. (200°-215° at 10 mm.). Formed from sodium cyano-succinic ether and chloro-acetic ether (Haller a. Barthe C. R. 106, 1413). White crystals, sol. alcohol and ether.

Methyl ether of the mono-nitrile CO₂Me.CH₂C(CN)(CO₂Me).CH₂CO₃Me. [47°]. Prepared in like manner (Barthe, C. R. 111, 344). Prisms, insol. water and alkalis.

Propane pentacarboxylic acid

CH(CO₂H)₂C(CO₂H)₂CH₂CO₂H. [151°]. Got by saponifying its ether. Spherical aggregates (from ether).—K₄A^{*} 4aq.—Ba₂A^{*}₂ 4aq: orystalline pp.

Ethyl ether Et,A. (275°-280° at 188 mm.). S.G. ¹⁵/₁₅ 1·121 (Bischoff, B. 15, 1107; 21, 2118). Formed from sodium-malonic ether and CCl(CO,Et),CH,CO,Et. Formed also from sodium ethane tricarboxylic ether and chloroscetic ether. Oil.

Reference.—OXYPROPANE TRICARBOXYLIC ACID.

PROPANE PHOSPHONIC ACID

C₁H₁.PO(OH)₂. [60°-70°]. Prepared by oxidation of propyl-phosphine with fuming HNO₂ (Hofmann, B. 6, 304). Wax-like mass, sol. water.

PROPANE SULPHONIC ACID

CH₂·CH₂·CO₄·

Propane sulphonic acid (CH₃)₂:CH.SO₃H. (below 100°). Formed by oxidising isopropyl mercaptan with HNO₃. Obtained also from acetone by successive treatment with P₂S₃ and HNO₄ (Claus, B. 5, 660; 8, 533; Spring, Bl. [2] 40, 66). Crystalline. Its salts are v. e. sol. water.

Propane disulphonic acid
CH₄(SO₂H).CH₂,CH₂(SO₂H). Formed by boiling
trimethylene bromide with a saturated solution
of ammonium sulphite (Monari, B. 18, 1345).
Deliquescent needles, v. sol. water and aloohol.—
Na,A'' 4\$q.—BaA'' 2aq: very soluble needles.

Propane disulphonic acid
OH.-CH(SO₃H).CH₂(SO₂H). Formed in like
manner from propylene bromide (M.).—Na₂A"aq.
—BaA": sparingly soluble crystals.

Propane disulphonic acid C₂H₂(SO₂H)₂. Got from butyramide and fuming H₂SO₄ (Buckton a. Hofmann, A. 100, 153), and also by heating butyric acid with ClSO₃H at 140° (Baumstark, A. 140, 83).—BaA".—PbA": crystalline.

Propane trisulphonic acid

CH.(SO₃H).CH(SO₃H).CH₂(SO₃H). Got by boiling s-tri-chloro-propane with aqueous K₂SO₃ (Schäuffelin, 4. 148, 117).—Ba₂A'''₂: crystalline powder, sl. sol. water.

References.—CHLORO- and OXY-PROPANE SUL-

PHONIC ACID.

DIPROPARGYL C.H. i.e.

CH:C.CH., CH., CiCH. Hexmene. (86°). S.G. 12 · 81. H.F.p. - 96,040. H.F.v. - 97,200 (Thomsen, Th.). Formed by distilling diallyl tetrabromide with solid KOH, and boiling the resulting dibromo-diallyl with alcoholic potash (Henry, B. 6,956; 7,21; 14,399; 17,1132). Limpid, highly refractive oil, v. sol. ether. Burns with smoky flame. Combines with explosive violence with bromine, forming C,H,Br, a thick liquid S.G. 12 · 2·464, from which, by further action of Br, crystalline C,H,Br, (14¹) can be obtained. Iodine in KI forms dipropargyl tetraiodide C,H,I, [113°] crystallising from CS, in prisms. Dipropargyl gives with ammoniacal cuprous chloride a yellow pp. Cu,C,H, 2aq, which explodes below 100°. Dipropargyl is very easily polymerised, forming a resin.

PROPARGYL ALCOHOL C₂H₁O i.e.
CH:C.CH₂OH. Mol. w. 56. (115°). V.D. 1:88
(calo. 1:93). S.G. ²⁰ :9715. μ_B = 1:437. R_∞
= 24:01 (Brühl). H.F.p. = 3,500. H.F.v. = 4,370
(Thomsen, Th.). Formed by boiling bromoallyl alcohol with KOHAq (Henry, B. 5, 274,
449, 569; 6, 728; 7, 20, 761). Formed also
from propargylamine oxalate, NaNO_a and HCl
(Paal a. Hempel, B. 24, 3039). Colourless
liquid of peculiar odour, sol. water.

Reactions.—I. Ammoniacal Cu_.Cl₂ ppts. canary-yellow Cu_.(C₂H_.O)₂ which explodes when heated, and is decomposed by dilute acids with reproduction of propargyl alcohol.—2. Ammoniacal AgNO₃ ppts. white AgC₂H_.O,—3. Anhydrous BaO forms Ba(C_.H_.O)_.C₂H_.O, crystallising in small plates.—4. On heating with solid KOH it yields formic acid and acctylene.—5. HBr forms bromo-allyl alcohol.—6. HNO₃ yields CO₂

Acetyl derivative C.H., OAc. (125°). S.G. 9 1.0052. $\mu_{\beta} = 1.427$. $R_{\infty} = 39.71$ (Brühl). Got from the alcohol and AcCl.

and oxalic acid.

Methyl ether C.H.OMe. (62°). S.G. 125°83. H.F.p. -10,910. H.F.v. -12,360 (Thomsen, Th.). Formed by boiling s-tri-bromo-propane with KOH dissolved in MeOH (Liebermann, A. 135, 287) and by boiling the dibromide of methyl allyl oxide with alcoholic potash (Henry). Ammoniacal AgNO, ppts. lemon-yellow C.H.Ag.OMe, whence I in KI forms oily C.H.LOME [127].

Ethyl ether C.H., OEt. (81°-85°). S.G. 2°-8326. μ₈-1·4096. R_∞ = 39·5 (Brühl). This body is formed by the action of alcoholic potash on CH₂Br. CHBr. CHBr. on CH₄·CBr₂·CH₂Br₄

on dichluropropylene, or on ethyl bromo-allyl oxide (Liebermann, A. 135, 278; 158, 230; Henry, B. 5, 274; Baeyer, A. 138, 196). Mobile liquid, with penetrating odour, v. sl. sol. water, miscible with alcohol. Combines with Br, forming C, H, Br, OEt. Boiling very dilute (1 p.c.) H.SO, splits it up into alcohol and propargyl alcohol. Sodium forms C.H.NaOEt. Alcoholic silver nitrate forms crystalline (C₃H₂Ag.OEt)₂AgNO₃ converted by ammonia into amorphous C₃H₂AgOEt, whence I in KI forms crystalline C.H.IOEt and oily C.H.I.OEt. An ammoniacal solution of AgCl added to an alcoholic solution of C,H,OEt ppts. white (C₃H₂AgOEt) AgCl. Ammoniacal Cu₂Cl₂ gives yellow amorphous C₃H₂CuOEt.

Isoamyl ether C₂H₃OC₃H₄. (140°-145°). PROPARGYLAMINE C₂H₃NH₄. Formed by the action of NaOEt on bronno-allyl-amine and on di-bromo-propyl-amine (Paul a. Hermann, B. 22, 3080). The free base has not been isolated. -B'H₂C₂O₄. [143°]. Large tables (from water), al. sol. alcohol. Gives a white pp. with ammoniacal AgNO₃.—B'C₃H₁(NO₃), OH. [189°]. Large red plates or tables.—B'HCl.—B'HBr. [130°-171°].—B'HI. [205°]. White plates, v.

e. sol. water.

PROPARGYL-ISOAMYL-AMINE C.H., N i.c. C3H2NHC5H11. Formed from di-bromo-isoamylamine and NaOEt (Paal a. Hermann, B. 22, 3084). Liquid.—B'H.C.O. aq. [204]. White needles (from water).—B'HBr. [186°]. Pearly plates.

PROPARGYL BROMIDE CH; C.CH.Br. (89°). S.G. M 1-59. Formed from propargyl alcohol and PBr_s (Henry, B. 6, 728). Liquid.

Propargyl tribromide v. Tat-bromo-propyl-

PROPARGYL-ISOBUTYL-AMINE C.H., N i.e. CH;C.CH, NH.CH, Pr. (135"). Formed from di-bromo-propyl-isobutyl-amine and NaOEt (Paal a. Heupel, B. 24, 3045). Liquid, miscible with water.—B'HCl. [148°].—B'H,PtCl., [210°]. Needles and plates, m. sol. cold water.

PROPARGYL CHLORIDE C.H.Cl. S.G. 1 1045. Formed from propargyl alcohol and PCl₂ (Henry, B. 8, 398). Mobile oil. PROPARGYLIC ACID is PROPIOLIC ACID

PROPARGYL IODIDE CH:C.CH,I. (c. 115°). S.G. 2 2 018. Formed from propargyl bromide and NaI in alcohol (Henry, B. 17, 1132). Yellowish liquid. Iodine forms CHI:CI.CH,I. [41°].

PROPARGYL-PROPYL-AMINE C.H., N i.e. C,H,NH.C,H, The salt B'HBr [180°] is got from propyl bromide and propargylamine (Paal s. Hermann, B. 22, 3084)

PROPARGYL SULPHOCYANIDE C.H.SCN. Formed from propargyl bromide and potassium sulphocyanide (Henry, B. 6, 729). Oil, smelling like mustard. Decomposed by heat.

PROPARGYL-DI-THIO-CARBAMIC ACID CH:C.CH, NH.CS, H. [115°]. Formed by boiling propargylamine with CS, and alcohol (Paal a. Heupel, B. 24, 3041). Needles (from dilute alcohol) or plates (from benzene-ligroin).
PROPENYL-o-AMIDO-PHENOL

OXYLIC ETHER C.H. < O > CMe.CH. CO.Et. [108°]. Formed by heating a mixture of o-amidophenol and acetoscetic ether (Hantzsch, B. 16, from the fruit of Cucumis prophetarum, split up

1948). Flat prisms, readily resolved into the parent substances by dilute acids, alkalis, or even boiling water.

PROPENYL-o-AMIDO-PHENYL MERCAP. TAN C.H., NS i.e. C.H. < N > CEt. (252°). Formed by heating o-amido-phenyl mercaptan with propionyl chloride at 160° (Hofmann, B. 13, 21). Heavy oil.—B'2H2PtCla: large prisms.

PROPENYLAMINE CH., CH; CH.NH. Formed by the action of baryta on β-bromo-propylamine (Hirsch, B. 23, 968). Does not propylamine (Hirsch, B. 23, 968). Does not decolourise bromine water.—B',H,I,2BiI,: sixsided plates.

PROPENYL-BENZENE SULPHONIC ACID CH.: CMe.C.H..SO.H. The salts of this acid are formed by heating the dry salts of the acid CMe, (OH). C, H, SO, H (R. Meyer, A. 219, 802).

Amide C, H, SO, NH, [1520].

o-PROPENYL-BENZOIC ACID CH₂:CMc.C₆H₄.CO₂H. [61°]. Formed from dimethyl-phthalide and KCy at 260° (Wislicenus, A. 248, 64). Needles (from water).

p-Propenyl benzoic acid CH₂CMe.C₆H₄.CO.H. [161°]. Formed by heating (CH₂)₂.C(OH).C₆H₄.CO₂H with dilute HCl on a water bath (R. Meyer a. J. Rosicki, B. 11, 1791; A. 219, 270). White satiny plates (from 1 pt. alcohol and 1 pt. water) or slender needles (from water). Sl. sol. hot water, v. e. sol. alcohol and other. Sodium amalgam reduces it to cuminic acid.

Salts. - NH,A'. - BaA', aq. - CuA', 7aq. -AgA': amorphous pp.

Methyl cther. MeA' [53°]. (254° cor.).

V.D. 6.09. Insol. water.

Isopropenyl-benzoic acid C,H,.C,H,.CO,H [255°-260°]. By boiling oxy-propyl-benzoic acid (CH₂)_C(OII).C₂II₂.C₂H with fuming HCl (B. Meyer, B. 12, 1076; A. 219, 281). Minute needles grouped in stars (from alcohol). Insol. water. Does not decolourise bromine, and is not reduced by sodium amalgam, but is converted by HI into cuminic acid. Hence it would appear to be a polymeride of propenyl-benzoic acid, not containing a C:C group.

Salts.—NH, A' aq. Sl. sol. water.—BaA'₂ aq. CaA'₂ 1½aq.—CuA'₂—AgA': pp., insol. water.

Methyl ether MeA'. [83']. Decomposed by heat.

PROPENYL-PHENOL. Methul derivative v.

PROPENYL-ISOPROPYL BENZENE C, H, i.e. Pr.C.H., CH.CHMe. (230°). S.G. 13. 890. Got by boiling Pr.C.H., CH., CBrMe.CO.H with Na.CO.Aq (Perkin, C. J. 1877, ii. 660). Dibromide C., H., Br. [59°]. PROPENYL-SALICYLIC ACID v. OXY-FRO

PENYL-BENZOIC ACID.

PROPERTONE v. PROTEÏDS.

PROPHETIN CasHasO,. A bitter resin got

by boiling dilute HClAq into glucose and prophetein C. H. O. (Walz, J. 1859, 566).
PROPINENE v. ALLYLENE.

PROPINENE DIPHTHALIDE C, H12O, i.e. O.CO C.H. Formed by -Ç:CMe.CH:Ç-C.H. < CO. ò

heating phthalic anhydride (3 pts.) with pyrotartaric acid (3 pts.) and sodium acctate (1 pt.) at 240°-290° (Roser, B. 17, 2776). Fine yellow needles, not melted at 280°.

PROPIO-GUANAMINE C.H.N. CH,Me.C:N.C(NH) NH. Got by heating guanidine propionate at 230° for an hour (Haaf, J. pr. [2] 43, 78). Granules (from NaOHAq) or dimetric prisms (from water).

PROPIO-HOMO-FERULIC ACID v. DI-OXY-

PHENYL-CROTONIC ACID

PROPIOLIC ACID C.H.O., i.e. CH:C.CO.H. Propargylic acid. [6°]. (c. 144°). Formed by boiling the acid K salt of acetylene dicarboxylic acid with water (Bandrowski, B. 13, 2340). Liquid, solidifying at about 4°. Smells like acetic acid. Turns brown in air. Sol. water, alcohol, and ether. Reduces HgCl₂, AgNO,, and

Reactions. - 1. Ammoniacal AgNO, gives a white crystalline explosive pp.-2. Ammoniacal Cu, Cl, gives a green amorphous explosive pp., turning brown. - 3. Sodium-amalgam reduces it to propionic acid .- 4. Combines with HCl, forming \$-chloro-acrylic acid. HBr and HI act in like manner .- 5. Br forms di-bromo-acrylic acid [85°]. - 6. I forms CHI:CI.CO.H [104°] (Bruck, B. 24, 4120).

Salt .- KA' aq. Transparent prisms, v. sol.

water, deflagrating at 105°.

Ethul ether Eth'. (119°). V.D. 3.47. Liquid, smelling like horse-radish. Oxidised by alkaline K.FeCy, to diacetylene dicarboxylic acid (Baeyer, B. 18, 677, 2269).

Reference. - BROMO- and IODO- PROPIOLIC

PROPIONAMIDE v. Amide of PROPIONIC

PROPIONAMIDINE C.H.N. i.e.

CEt(NH).NH. The hydrochloride is formed by leading HCl into a solution of propionitrile in isobutyl alcohol, and heating the product with alcoholic NH, (Pinner a. Klein, B. 11, 1484; 17, alcohold Nr., (Pinier a. Riell, B. 1, 1494; 17, 176; 18, 2845). Very unstable oil, sl. sol. ether. On heating with NaOAc and Ac, 0 it yields a base C,H,N, [2049.—B'HCl. [1299]. Needles, insole ether.—B',H,PtCl., [2009].—B'HNO., [1169]. Crystals (from alcohol), v. sol. water (C. Lossen, A. 265, 167).

Reference. -- OXY-PROPIONAMIDINE. PROPIONE v. DI-ETHYL KETONE.

PROPIONIC ACID C,H_O,i.e. CH_, CH_, CO_, H.

Metacetonic acid. Mol. w. 74. [-23] (Petterson, J. pr. [2] 24, 295). [140·7° cor.) (Zander).

S.G. 3° 9946 (B.); 1½ 9983; 3½ 9896 (Perkin).

M.M. 3*462 at 20° µ_p = 1-391. R_∞ = 28·01 (Brthh). S.V. 85°3. C.E. (0°-10°) 00106. H.F.p. 100.450. H.F. 107.10 (Thomson Th.) S. H. 109,450. H.F.v. 107,710 (Thomsen, Th.). S.H. 440 at 0° (R. Schiff, A. 234, 800). Oritical temperature 340° (Pawlewski, B. 16, 2634). Occurs in the fruit of Gingko biloba (Bechamp, A. 180, 864), in suint (Buisine, Bl. [2] 48, 639), and in wood vinegar (Anderson, C. N. 14, 257; Barré, Z. [2] 5, 445).

Formation .- 1. By exidation of metacetone with chromic soid (Gottlieb, A. 52, 121) .- 2. By potash-fusion from sugar, starch, mannite, and angelic acid (G.).—3. By reduction of acrylic acid (Linnemann, A. 125, 317), of lactic acid (Lautemann, A. 113, 217), and of pyruvic acid (Wislicenus, A. 126, 229).—4. By heating potassium oxalate with dry NaOEt (Van't Hoff, B. 6, 1107).—5. By heating NaOEt with CO at 180° (Fröhlich, A. 202, 290; cf. Hagemann, B. 4, 877).—6. From ZnEt,, sodium, and CO, (Wanklyn, A. 107, 125).—7. Together with di-ethyl ketone, by heating ZnEt, with CO, at 160° (Schmitt, J. pr. [2] 42, 568).—8. By the action of sunlight on a solution of succinic acid containing a uranium salt (Seekamp, A. 133, 253). 9. By heating barium succinate with NaOMe for 3 hours at 300° (Mai, B. 22, 2133).—10. Among the products of destructive distillation of colophony (Renard, C. R. 103, 157).

Preparation.-1. By oxidation of n-propyl alcohol (Pierre a. Puchot, A. Ch. [4] 28, 75).— 2. By saponification of the nitrile (Linnemann, A. 148, 251; Beckurts a. Otto, B. 10, 262). 3. By heating lactic acid with HIAq (Freund, J. pr. [2] 5, 446).

Properties .- Liquid, miscible with water, alcohol, ether, benzene, and ligroin. Separated from its aqueous solution by CaCl₂, but not by NaCl and Na, SO₄. Heated in a scaled tube with ICl, it gives C₄Cl₈, CO₂, and HCl (Krafft, B. 9, 1085). On boiling the dry acid with Br and P for some time the product is α-bromo-propionic acid (Volhard, A. 242, 141).

Salts.—NH,A'.—(NH,)HA', (Sestini, Z. 1871, 34).—NaA'. S. 99 at 15°; 187 at 100° (R.). S. (alcohol) 2·4 at 20°, 3 at 100°.—NaA'aq.— KA'aq: deliquescent plates (Renard, C. R. 104, 913). S. Chloride C.H. COCl. (80°). S.G. 20 1.0646 (Brühl, A. 203, 14; cf. Sestini, Bl. [2] 11, 470). $\mu_{\theta} = 1.4107$. $R_{\infty} = 34.12$. ZnMe₂, followed by water, forms methyl ethyl ketone and oily C₈H₁₄O (168°). S.G. ^o 877 (Pawloff, A. 188,

138).

Bromide C,H,OBr. (104° i.V.). S.G. 25
152 (Lobry de Bruyn, R. T. C. 3, 389).

Iodide C.H.OI. (128°). Anhydride (C.H.O).O. Mol. w. 130. (162°) at 708 mm. (L.); (165°) (Limpricht a. Uslar, A. 94, 322); (167°) (Kahlbaum, B. 16, 2481); (169°) (Perkin, C. J. 28, 10). Formed by the action of Pb(NO₃)₂ (also of nitrates of other heavy metals) upon propionyl chloride; PbCl2 is formed, and N.O. and oxygen evolved; the yield is 77 p.c. of theoretical (Lachowicz, B. 18, 2991). Reacts with hydroxylamine hydrochloride, forming CH, CH, C(OH): NOH [85°] (Miolati, B. 25, 700).

73. [79²]. (213²). H.C.p. 436,000. H.C.v. 435,600. H.F. 88,400 (Berthelot, C. R. 111, 145; A. Ch. [6] 22, 20; Bl. [3] 4, 229). Formed from propionic ether and NH, (Dumas, C. R. 25, 657; Sestini, Cimento, 4, 21; L. Meyer, B. 22, 24). Prepared by heating ammonium propionate at 230° under pressure; the yield being 55 p.c. of the theoretical amount (Hofmann, B. 15, 981). Got also by heating propionic acid (46 g.) with ammonium sulphocyanide (18 g.) for 4 days, and distilling the product (J. Schulze, J. pr. [2] 27, 517).—B'₂HCl. Needles, v. e. sol. water, v. sl. sol. ether. - Hg(NH.C,H,O), Large dimetric plates, sl. sol. cold water.

Bromo-amide C.H.O.NHBr. [80°]. Formed from propionamide, bromine, and KOHAq (Hofmann, B. 15, 753). Colourless needles, sol. alcohol. Converted by hot KOHAq into ethylamine. - C.H.O.NNaBr. [c. 100°]. Needles.

Acetyl-amide O.H.O.NHAc. [82°]. (230°-). Formed from propionamidine hydroshloride, NaUAc, and Ac,O, a compound C,H,,N,

[204°] being formed at the same time (Pinner, B. 22, 1604).

Imide (C₄H,O)₂NH. [154*] (Otto a. Tröger, B. 23, 759). (210°-220°). Formation.—1. By heating the amide in a current of HCl.—2. By heating the amide with the chloride and AlCl₄.— 3. By the action of AlCl, at 100° on a mixture of propionitrile with AcCl or propionyl chloride. 4. By heating propionic acid with propionitrile for some hours at 200°. Properties. - Rectangular tables or silky needles, sl. sol. cold water. May be sublimed.

Anilide C,H,ONHPh. [105°]. S. 42 at 24°. Formed by heating the amide with aniline (Kelbe, B. 16, 1200). Plates, sol. other. With oxalio ether, benzene, and NaOEt it forms CO.CO NPh [192°] (Wislicenus a. Sattler,

B. 24, 1256).

Methyl-arilide C.H.O.NPhMe. [58.5°]. Formed from the anilide and Mel (Norton a. Allen, B. 18, 1998).

Ethyl - p - toluide C.H.O.NHC,H.Me. (c. 270°). From the chloride and ethyl-toluidine

(Norton a. Livermore, B. 20, 2271).

(Norton a. Livermore, B. 20, 2271).

Nitrile O.H.N. i.e. Et.CN. Propionitrile.

Ethyl cyanide. (97°). S.G. ½ 7998; \$\frac{3}{2}\frac{3}{2}\frac{1}\frac{1}{2}\frac{1}{2}\frac{1}{2}\frac{1}{2}\frac{1}{2}\frac{1} boiling KCy with EtI and alcohol (Williamson, P. M. [4] 6, 205; Buckton a. Hofmann, C. J. 9, 250; Rossi, A. 159, 79). -3. From the amide and P₂O₅ (Dumas, A. 64, 334). 4. From ZnEt₂ and cyanogen or CyCl (Gal. Z. 1868, 252; Frankland a. Graham, C. J. 37, 740). - 5. By the action of Ac.O on the oxim of propionic aldehyde in the cold (Dollfus, B. 25, 1915). Preparation. -The nitrile cannot be freed from alcohol by distillation, since the compound C,H,N3HOEt boils constantly at 79°, and is not decomposed by water or CaCl2. It is best, therefore, to prepare it from the amide. Properties. - Colourless liquid, v. sol. water, but separates on addition of NaCl or CaCl2. Miscible with alcohol and other. Combines with metallic chlorides, yielding (C,H,N)SbCl,, C,H,NAuCl,, C,H,NPtCl,, (C,H,N),SnCl,, and (C,H,N),TiCl, (Henke, A, 106, 280). Forms also (C.H.N.).TiCl. (Henke, A.106, 280). Forms also (C.H.N.).FcCy, 6aq. (C.H.N.).FcCy, 2aq (C.H.N.). FcCy, 2aq (Than, A. 107, 315). Reactions.—1. Potash forms propionic acid. Dilute H.SO, acts in like manner, 2. Dry chlorine forms CH., CCl., CN (Otto, A. 116, 195).—3. Bromine forms C.H.NBr, [64], converted by water into (C.H.BrO). NH (Engler, A. 142, 65).—4. Dry Hol slowly forms C.H.NCl. [1212] (Gautier, A. 142, 289). while HBr gives [121] (Gautier, A. 142, 289), while HBr gives C,H,NBr, [50°-55°] (Engler, A. 149, 807). Hi below 0° forms EtCl,NH, crystallising in plates (Bitz, B. 25, 2542).—5. Sodium converts it on heating into the polymeric cyanethine (q. v.). Sodium added to its solution in dry ether gives off H and ethane, and forms a product which is left when the ether is evaporated as a white powder (Et.C(NH).CMeNa.CN?). This powder is con-

verted by water into C.H., N. [48°] (258° uncor.). and by HClAq into C.H., NO or C.H., CO.CHMeCN (198.5°). The white powder treated with MeI yields C.H., N. (48°) (262°), whence HClAq forms liquid C.H., NO (175°), S.G. 2°945, mol. w. 125 (obs.). Etl and HClAq acting on the white powder yield C₈H₁₃NO (195°), S.G. 2 ·943 (E. von Meyer, J. pr. [2] 38, 336; Hanriot a. Bouveault, C. R. 108, 1171; Bl. [3] 1, 551). The compounds C,H₁₁NO and C,H₁₂NO are converted by heating with HClAq in scaled tubes into ethyl isopropyl ketone and ethyl butyl ketone respectively .- 6. A mixture of propionitrile and benzonitrile in ethereal solution is converted by Na, followed by water, into CPh(NH).CHMe.CN [97°], whence warm dilute HClAq forms oily C.H. CO.CHMe.CN (E. von Meyer, J. pr. [2] 39, 189).—7. Zinc and HClAq yield propylamine together with smaller quantities of di- and tripropylamine (Pisanello, G. 16, 446).—Ac₂O at 200° forms C₇H₁₄N₂O₂ [68°] (220°) (Gautier, Z. 1869, 127).

References .- AMIDO-, BROMO-, BROMO-NITRO-, CHLORO-, CHLORO-BROMO-, IODO-, NITRO-, and OXY-AMIDO-PROPIONIC ACID and PROPIONITRILE.

PROPIONIC ALDEHYDE C.H.O The property of the property by oxidation of propyl alcohol (Michaelson, A. 134, 69; Chancel, A. 151, 301; Lieben a. Zeisel, M. 4, 14) and by distilling calcium formate with calcium propionate (Rossi, C. R. 70, 129). Pungent liquid, sol. water. Readily oxidised by air. Reduces ammoniacal AgNO₂, forming a mirror. Readily dissolves in aqueous NaHSO. Decomposed by hot KOHAq. Coloured brownish-red by alkaline sodium nitroprusside, the colour being destroyed by HOAc (Von Bitto, A. 267, 876).

Reactions.-1. Reduced in aqueous solution by sodium-amalgam to n-propyl alcohol .-2. H₂S passed into its aqueous solution, acidified by HCl, forms oily (C₂H₈S)C₂H₆O (Alexejeff, B. 10, 1739).-8. Dry ammonia passed into propionic aldehyde dissolved in ligroin cooled by a freezing mixture forms a white flocculent pp. of C.H. (OH)NH., which readily deliquesces, forming O₁₁H₁₀N, [74°], crystallising in triclinic tables, a.b.c = 1:1·185: 801, insol. water, sol. alcohol and cther (Waage, M.4, 708).—4. PH, and HCl form (CH, CH₂, CH₂), PH, Cl [128°], while PH₃ and HBr give (C,H₄O), PH, Br [106°]. These compounds are decomposed by water (Messinger a. Engels, B. 21, 331). PH, at 0° forms, in like Engels, B. 21, 351). PH,1 at 0° forms, in like manner, (O₂H₂O),PH₂I [96°] (Girard, A. Ch. [6] 2, 24). — 5. Mercaptan and ZnOl, give OH₂CH₂CH₃(SEt)₂ (198°) (Fromm, A. 253, 150). 6. Propyl alcohol and HOAc at 100° form OHEt(OPr)₂ (166° cor.) (Schudel, M. 5, 247).

Oxim C.H., CH.NOH. (181°). Formed from the aldehyde and aqueous hydroxylamine (Petraczek, B. 15, 2784). Liquid, sol. water. It is a syn-oxim, because it is converted by Ac O and ether in the cold into propionitrile (Dollfus, A. 25, 1915).

Phenyl-hydraside CHEt:N.HPh (152° in vacuo) (Bischoff, B. 23, 1916).

References .- Brown CHLORO . IODO . and OXY- PROPIONIC ALDEHYDE.

PROPIONIC IMIDO-ETHYL ETHER

C2H3.C(NH).OEt. The hydrochloride, B'HCl, formed by passing gaseous HCl into a mixture of propionitrile and alcohol diluted with ether (\frac{1}{3}\times vol.), crystallises in prisms, decomposing at about 92° into EtCl and propionamide (Pinner, B. 16, 1654).

PROPIONITRILE v. Nitrile of PROPIONIC

PROPIONYL-ACETOPHENONE v. PHENYL-METHYLENE-ETHYL-DIKETONE.

PROPIONYL-BENZOIC ACID v. PHENYL ETHYL KETONE CARBOXYLIC ACID.

PROPIONYL BROMIDE v. Bromide of Pro-PIONIC ACID.

PROPIONYL-BUTYRIC ACID

C,H,.CO.CMe,.CO,H.

Methylether MeA'. (188° uncor.). Formed by the action of MeOH and HCl on the nitrile C₂H₃.CO.CMe₂.CN (175°), which is got by the action of cold HCl upon C₂H₃.C(NH).CMe₂.CN [43°] which is made by the action of McI on the product of the action of Na on propionitrile (Bouveault, C. R. 111, 531). Liquid.

PROPIONYL CHLORIDE v. Chloride of Pro-

FIONIC ACID.

PROPIONYL CYANIDE C.H.NO i.e.

CH3.CH2.CO.CN. (109°). Prepared by heating organized (12 g.) with silver cyanide (8 g.) in closed tubes for 1 hour at 100°. The product is fractionally distilled (Claisen a. Moritz, C. J. 37, 692). HCl converts it into ethylglyoxylic acid (q. v.).

Di-propionyl di-oyanide (Et.CO) C.N. [59°]. (208°). V.D. 5-6 (calc. 5-7). Obtained in the preparation of the preceding (C. a. M.) and by the action of AgCy on propionyl bromide (Lobry de Bruyn, R. T. C. 3, 390). Prisms, sl. sol. water, sol. alcohol and ether.

PROPIONYL-CYANO-ACETIC ETHER v. ANO-ACETIC ACID.

PROPIONYL-MALONIC ETHER C₁₀H₁₀O₅ i.e. C_{.H.2}, CO.CH(CO₂Et)₂. (239°-242° uncor.). Formed by the action of propionyl chloride upon sodio-malonic ether (Lang, B. 20, 1326). Colourless liquid.

PROPIONYL-PHENOL v. OXY-PHENYL ETHIL

a-PROPIONYL-PROPIONIC ACID C.H.,O.

i.e. CH, CH, CO.CHMe.CO,H.

Methyl ether C,H, CO.CHMe.CO,Mo or
C,H, C(OH):CMe.CO,Me. (187° cor.). S.G. 22
107. Formed by the action of Na on methyl propionate (Pingel, A. 245, 84). Colourless liquid with aromatic odour. Converted by ammonia into C,H₁₃NO₂ and a hygroscopic substance C₁₂H₁₂N,O₄(?) [82°]. Aniline forms oxymethyl-ethyl-quinoline [295°] (Bouveault, C. R. 111, 41). NaOHAq yields a mixture of di-ethyl ketone and methyl cthyl ketone. NaOEt followed ketone and methyl cthyl ketone. NaUEt followed by alkyl iodides yields the alkyl derivatives: C.H., MeO. or CEt(OMe):CMc.CO.Me [194°], C.H., EtO. (208°), C.H., PrO. (220°), and C.H., (CH.Pr)O. (231°), all being liquid.

Ethyl ether Eth. (199°). S.G. 2 -995;

12 983. Formed by digesting propionic ether in EtO. with Na. (Origentain a. Hellon B. 10.

in Et.O with Na (Oppenheim a. Hellon, B. 10, 699; Israel, A. 231, 197). Gives no colour with FeCl. Ammonia forms C.H., NO. (195°), insol.

water, and a hygroscopic substance [75°]. NaOHAq forms di-ethyl ketone. NaOEt and NaOHAq forms di-ethyl ketone. NaOEt and EtI yield propionic ether and CH, CHEt.CO, H (Genther, A. 239, 386). Na followed by Etl added to the solution in benzene forms C.H., C(OEt): CMe.CO, Et (206°), S.G. 12 966. Reduced by HI and P to CHMePr.CO.H (1932). Nitrous acid yields CH, C(NOH).CO.Et [94] (Hantzsch a. Wohlbrück, B. 20, 1320).

C,H,O.CHMe.CO.NH., Amida Formed by adding water to the product of the action of AlCl, on a mixture of propionyl chloride and propionitrile (Otto a. Tröger, B. 22, 1455).

Needles, sl. sol. cold water.

Nitrile C.H.CO.CHMe.CN. Nitrile C.H. CO.CHMe.CN. (c. 188°).

Formed by the action of cold conc. HClAq on the product of the action of Na on propionitrile (Meyer, J. pr. [2] 38, 339). Oil. Converted by ammonia into the imide [45°]. Hydroxylamine forms the oxim C.H., C(NOH), CHMe, CN [44°] (180° at 200 mm.) (Hanriot, C. R. 112, 796). Aniline yields amido - methyl - cthyl - quinoline (Hanriot a. Bouveault, Bl. [3] 1, 552).

Propionyi-propionic acid CH, CH, CO.CH, CH, CO, H. [33°]. A product of the action of boiling water on di-bromo-hexoic acid (from hydrosorbic acid and Br) (Fittig, A. 268, 69). Crystalline, v. e. sol. water, alcohol, and ether. —CaA'₂1;aq: plates. —AgA'.

PROPIONYL - PROPIONIC ALDEHYDE

C, H, CO.CHMe.CHO. [c. 40°]. (165°). Formed by adding a well-cooled mixture of formic ether (11 g.) and di-ethyl ketone (13 g.) to NaOEt (10.5 g.) suspended in dry ether (10 g.). 12 hours the product is acidified and distilled under 50 mm. pressure (Claisen a. Meverowitz, B. 22, 3273). Crystals, v. sol. water. Deliquesces and turns brown in air. NH₃ forms deliquescent crystals of (C₈H₁₆O₂)NH₃. Cu(OAc)₂ added to its alcoholic solution forms Cu(C,H,O,j, [168]. Phenyl-hydrazine produces $C_{12}H_{11}N_2$ (283°).

PROPIOPHENONE v. PHENYL ETHYL KETONE.

PROPYL. The radicle CaH,. n-Propyl CH. CH. CII, changes in some reactions to iso-

propyl (CH,)2CH and vice versa.

Pr changes to Pr: 1. When cumyl alcohol is reduced to n-cymene by boiling with zinc-dust (Kraut, A. 192, 225; Jacobsen, B. 12, 434). -2. When cumyl chloride is reduced to n-cymene by zinc and HCl (J. 1879, 369). - 3. When nitro-cymylene chloride is reduced to n-cymidine by boiling with zine and HCl (Widman, B. 15, 166; 19, 245) .- 4. When isopropyl-cinnamic acid is reduced by sodium-amalgam to n-cumyl-propionic acid. -5. When o-amido-isopropyl-cinnamic acid is reduced by sodium-amalgam to (B. 5)-n-propyl-(Py. 3)-oxy-quinoline dihydride. Pr changes to Pr: 1. When n-cymene is

oxidised to cuminio acid—(a) by passing through the organism, (b) by air and gaseous NaOH (B.5,749; 12,512; 11,369; 14,1144).—2. When n-cymene sulphonic acid is oxidised to oxyisopropyl-sulpho-benzoic acid by alkaline KMnO. (Meyer a. Boner, B. 14, 1136, 2391; A. 220, 6). 8. When n-cymene is oxidised to oxyisopropylbenzoic acid by alkaline KMnO₄.—4. When thymol is oxidised by KOH fusion to the oxycuminic acid, which is obtained from m-nitrocuminic acid by reduction and diszotisation (Barth, B. 11, 1571).—5. When carvacrol (which contains n-propyl, since by distillation with P.S.

it gives n-cymene) is oxidised by KOH fusion to the oxy-cuminic acid [93°], which is obtained from o-amido-cuminic acid by diazotisation (B. 6, 936; 9, 1061) .- 6. Since cuminol is always accompanied in plants by n-cymene, it is probably produced by oxidation of the latter.—7. When n-propyl bromide is boiled with AlBr. (Gustavson. C. J. 44, 565).

From the above may be deduced the general law: When a propyl group in a benzene derivative occurs in the para-position to Me, CHO, or CO.H., it is predisposed to be NORMAL by Me, 180 by CHO or CO.H (Widman, B. 19, 251, 273,

DI-PROPYL ACETAL v. ALDEHYDE. PROPYL ACETATE v. Acetyl derivative of PROPYL ALCOHOL.

PROPYL-ACETIC ACID v. VALERIC ACID.

Di-propyl-arstic acid v. Octobe Acid. PROPYL-ACETOACETIC ETHER v. vol. i. p. 23.

DI-PROPYL-ACETONE V. METHYL HEPTYL RETONE PROPYL-ACETYLENE v. PENTINENE

DI-PROPYL-ACRYLIC ACID v. ENNENOIG

n-PROPYL ALCOHOL C.H.O i.e. СП₂СП₂СП₄ОН. Mol. w. 60. (97·4° i. V.). S.G. § *8177 (Zander, A. 224, 79); 15 *8088; 25 *8025 (Perkin); 20 *8044 (Bruhl, A. 203, 268). C.E. S.H. 670 (Diaconoff, Bl. [2] 38, 172). Qurs in fusel oil, especially in that of wine (Chancel, C. R. 37, 410; 68, 659, 726; Pierre a. Puchot, C. R. 66, 302; 70, 406; Linnemann, A. 160, 195; Fittig, Z. [2] 4, 44; Ekman, Chem. Zeit. Thus 40 g. of it were found in 100 12, 564). litres of old cognac (Ordonneau, C. R. 102, 217; Clandon a. Morin, C. R. 104, 1187; 105, 1019). A litre of potato-fusel oil was found to contain 30 c.c. of n-propyl alcohol, 150 c.c. of isopropyl alcohol, 115 c.c. of butyl alcohols, 335 c.c. of amyl alcohols, 125 c.c. of water, and 245 c.c. of other bodies (Rabuteau, C. R. 87, 501). Propyl alcohol also occurs, together with isopropyl alcohol, among the products of the lactic and butyric fermentation of sugar (Bouchardat, C. R. 78, 1145; Meyer a. Forster, B. 9, 535), and in the fermentation of glycerin (Fitz, B. 18, 36, 1311).

Formation .- 1. By reducing propionic anhydride with sodium amalgam (Linnemann, 4. 148, 251; 160, 231; 161, 18).—2. By adding sodium-amalgam and dilute H₂SO₄ to a solution of propionic aldehyde (1 pt.) in water (18 pts.) (Rossi, C. R. 70, 129).—3. By heating allyl alcohol with KOH (Tollens, Z. [2] 7, 242).

Properties.-Liquid with alcoholic odour, miscible with water, but separated from the solution by CaCl. Does not yield isopropyl alcohol when heated in sealed tubes (Aronstein, R. T. C. 1, 194). When propyl alcohol (71-46 c.o.) is mixed with water (28-54 c.o.), contraction (1-85 c.o.) is observed (Ramssy a. Young, C. J. Proc. 4, 101).

Reactions .- 1. Chromic acid oxidises it to propionic aldehyde and acid .- 2. HBr and H.SO, give propyl bromide, propylene bromide,

and C,H,Br, (Niemilovitch, M. 10, 820).—3. I and KOHAq form iodoform (Lieben, A. Suppl. 7, 280).—4. Fused ZnCl, forms propylene, isoutyl alcohol, CH,:CMe,, and CHMc:CHMe (Le Bel a. Greene, C. R. 89, 413).—5. Phosphoplatinous chloride followed by water forms crystalline P(OPr), PtCl, (Pomey, C. R. 104, 364).—6. Calcium chloride yields (C,H,O), CaCl, crystallising in needles (Göttig, B. 23, 181).

Metallie derivatives. KOPr (De Forcrand, C. R. 104, 68).—NaOPr2HDOR (Fröhlich, A. 202, 295). Ba₂(OPr)₂(OH)₂. Formed by heating propyl alcohol with BaO under pressure (Destrem, A. Ch. [5] 27, 32). Yields propylene, methane, and hydrogen when heated. The corresponding lime compound yields di-ethyl ketone when heated.—Al(OPr)₃. [c. 60°]. S.G. ± 1.026. Formed in small quantity from propyl alcohol, AlI₄, and Al (Gladstone a. Tribe, C. J. 39, 6). Isopropyl alcohol does not react in this way.

Acetyl derivative ProAc. Propyl acetate. (102°). S. 1.5 at 16° (Linnemann, A. 161, 30). B.G. 2° 9091 (E.); 2° 8856 (Brühl); 2° 9093 (Gartenmeister); 1½° 8933; 2½° 8840 (Perkin, C. J. 45, 421). C.E. (0°-10°) 001197 (Elsässer, A. 218, 320). S.V. 128·3. μ_S 1·3890. R_∞ 43·11. M.M. 5·487 at 15·2°. Liquid. Not changed into isopropyl acetate by heating in a sealed tube (Aronstein, R. T. C. 1, 134).

Bensoyl derivative BzOPr. (230° cor.). S.G. 14 1.032 (Linnemann).

Isopropyl alcohol (CH₃) CH.OH. (83° cor.). S.G. § '7996 (Zander); $\frac{15}{12}$ '7914; $\frac{25}{22}$ '7845 (Perkin); $\frac{2}{30}$ '7887 (Brühl, A. 203, 12.). $\mu_{\theta} = 1.8821$. R_{co} 27-99. M.M. 4-019 at 17-9°. S.V. 817 (R. Schiff, A. 220, 331); 82-8 (Zander). C.E. (0°-10°) 00108. H.F.p. 71,000. H.F.v. 69,970 (Thomson, Th.).

Formation.—1. By distilling PrO.SO₃H (made from propylene and H₂SO₃) with water (Berthelot, J. 1855, 611).—2. By reducing acetone or propylene oxide with sodium-amalgam (Friedel, A. 124, 327; Linnemann, A. 140, 178).—3. By heating a solution of n-propylamine nitrite (Linnemann, A. 161, 43; B. 10, 1111; Meyer, B. 9, 536).—4. By the action of sodium-amalgam on (CH₂Cl)₂CH₂OH dissolved in wet ether (Buff, Z. [2] 4, 124).—5. From CH₂I.CH₂OH by successive treatment with ZuMe₂ and water (Butlerow a. Ossokin, A. 145, 257).

Preparation.—1. Acetone (1 vol.) is diluted

Preparation.—1. Acetone (1 vol.) is diluted with water (5 vols.) and sodium-amalgam is slowly added. The liquid is distilled and the process repeated upon the distillate (Linnemann, A. 186, 87).—2. By boiling isopropyl iodide (1 pt.) with water (10 pts.) and Pb(OH)₂ (Flavitzky, A. 175, 880).—3. By heating isopropyl iodide (1 pt.) with water (20 pts.) at 100° for 40 hours (Niederist, A. 186, 891).

Properties.—Liquid with peculiar odour, not solid at -20°. Inactive to light. Miscible with water, yielding on distillation the hydrate (C₂H₂O)₂ 2aq (80°), S.G. 12 832. When K₂CO₃ is added to an aqueous solution of the alcohol a hydrate (C₂H₂O)₂ aq separates (Erlenmeyer, A. 126, 80°). After drying over CuSO₃ the hydrate (C₄H₂O)₃ aq (81°) S.G. 12 800 is left. Dilute CrO₃ forms acetone. Bromine forms acetone and FrBr.

Acetyl derivative ProAc. Isopropyl

acetate. (91°). S.G. 2 917 (Friedel, A. 124, 327; Pribram s. Handl, M. 2, 686).

Benzoyl derivative ProBz. (218°) (Silva, Bl. [2] 12, 225). Liquid. Split up by distillation into benzoic acid and propylene (Linnemann, 4. 161, 51).

References.—BROMO-, CHLORO-, CHLORO-IODO-, and IODO- PROPYL ALCOHOL.

PROPYL ALDEHYDE v. Propionic alde-

PROPYL-DI-ALLYL-CARBINOL v. DECINYL

PROPYLAMIDOACETIC ACID

NHPr.CH., CO₂H. Formed from CH₂Br.CO₂Et and NH₂Pr (Chancel, Bl. [3] 7, 409; C. R. 114, 756). Needles, v. sol. water and alcohol, insol. ether.—(HA'), H.PtCl_a aq.—CuA'₂2aq: crystals, v. sol. water and alcohol.

PROPYL-AMIDO-ISOPROPYL ALCOHOL C_aH_{1,5}NO *i.e.* CH₂CH(OH).CH₂NHC₃H₄. Formed by heating allyl-propyl-amine with H₂SO₄ (3\frac{1}{3}\text{pts.}) at 135° (Liebermann a. Paal, B. 16, 532).—B'₂H₃PtCl₄ 2aq: nodules (from water).

Di-propyl-amido-isopropyl alcohol CH₂.CII(OII).CH₂.N(C,H₂)₂. Formed in like manner from allyl-di-propylamine.—B'₂H₂PtCl₆.

n-PROPYLAMINE C3H3N i.e.

CH_,CH_,CH_,NH_, Mol. w. 59. (49°). S.G. $\frac{15}{2}$. 7222; $\frac{25}{2}$. 7144. H.F.p. 22,760. H.F.v. 20,420 (Thomsen, Th.). S.V. 85°6. M.M. 4°564 (Perkin, C. J. 55, 693). $\mu_D = 1°3873$ (Gladstone, C. J. 59, 290).

Formation .- 1. By reduction of propionitrile. Using 36 g. of propionitrile, 500 g. alcohol, 200 g. water, zinc, and 500 g. of 20 p.c. HClAq, the yield is 9g. (Mendius, A. 121, 129; Linnemann, A. 161, 44).—2. From n-propyl iodide by successions. sive treatment with silver cyanate and KOHAq (Silva, Z. [2] 5, 638).—3. By heating n-propyl iodide with alcoholic NH, and distilling the product with potash. The fraction boiling below 78° is mixed with alcohol and oxalic ether, and the di-propyl-oxamide [161.5°] thus formed distilled with alcoholic potash (Vincent, C. R. 103, 208). n-Propyl iodide heated with conc. NHAq for 13 hours at 100°-150° forms propylamine hydriodide and NPr.I (Malbot, A. Ch. [6] 13, 480, 546).-4. When n-propyl chloride is heated with aqueous ammonia in equimolecular proportions at 140°-165°, one-fifth of the product is n-propylamine and is nearly all contained in the lower layer. The upper layer consists of free di- and tri- propyl-amines, water, and alcohol (Malbot, C. R. 104, 998).—5. By heating n-propyl nitrate with alcoholic NH₂ at 100° (Wallach, A. 214, 311).

Walker, H. 24, 541, 11.

Preparation.—1. A mixture of equimolecular quantities of bromine and butyramide is run into an excess of a 10 p.c. solution of KOH at 60° and the propylamine distilled off; the yield is 80–90 p.c. (Hofmann, B. 15, 769). It may be dried over CaO and afterwards over Na.—2. PrOI (1 mol.) heated with aqueous NH, (1 mol.), and enough alcohol to effect solution, in sealed tubes at 110° forms 45 p.c. propylamine, 35 p.c. dipropylamine, and 20 p.c. tri-propyl-amine (Chancel, Bl. [3] 7, 405). The product is neutralised with HOI, the alcohol distilled off, cooled, filtered from separated NH, OI, the syrup mixed with NaOH, distilled, and fractionated.

The bases may be further purified by means of |Bl. [2] 46, 287) or of aqueous NH, on PrCl at their oxalates.

Properties .- Mobile liquid with ammoniacal smell; mixes with water, becoming hot. When wet it boils at 78°-82°. Its aqueous solution ppts. salts of Cu and Fe, the pp. not dissolving in excess, but with AgNO, it gives a pp. sol. AXCARS.

Reactions .- 1. Chromic acid yields propionic acid (Chapman a. Thorpe, A. 142, 176).-2. Nitrous acid forms n- and iso- propyl alcohols and propylene (Meyer a. Forster, B. 9, 535).-3.

Benzoic aldehyde forms C.H., CH.NPr (210°) (Zaunschirm, A. 245, 282).-4. Oxalic ether added to a mixture of equal volumes of propylamine and water forms CONHPr.CONHPr and CO2H.CONHPr [110], which yields CaA', 2aq. S. 1.38 at 17°.

Salts .- B'HCl. [158°] · (Topsoë, J. 1883, 621). -B'HHg,Cl, - B'HHg,Cl, -B'HAuCl, -921).—B HIR, Cli. — B HR, Cli. — B HAUCI.
F. H., PtCl., Monoclinic crystals. — Oxalate,
NH, Pr C., H., O., Laq. Plates. S. 14.8 at 18°; S.
(alcohol) 6 at 18°.—Pierate [135°].
Nitramine CH, CH, CH., NH, NO. (129°
at 40 mm.). S.G. 12 1 102. Formed by heating

PrN(NO2).CO2Et in a current of dry NH2, and decomposing the product with dilute II.SO₄ (Thomas, R. T. C. 9, 75). Liquid, crystallising at -23°. Decomposes at 142°. Sl. sol. water; decomposes carbonates. - PrNK.NO. Formed by dissolving the nitramine in alcoholic potash and ppg. with ether. Small pearly plates, forming an alkaline solution in water.-PrNAg.NO. Slender needles, blackening in light. AcCl yields N₂O.

Isopropylamine (CII,),CH.NH., (32°). S.G. 49 ·690.

Formation.-1. By the action of HClAq on isopropyl-carbamine (Siersch, A. 148, 263; Gautier, C. R. 67, 723). -2. By running a mixture of bromine (1 mol.) and isobutyramide (1 mol.) into an excess of a 10 p.c. solution of KOH at 60°; the yield being 65 p.c. (Hofmann, B. 15, 768).-3. By reducing acctoxim dissolved in alcohol with sodium-amalgam and HOAc at 40° (Goldschmidt, B. 20, 728).—4. By heating isopropyl iodide with conc. NH₃Aq (Malbot,

C. R. 111, 650; cf. Jahn, M. 3, 166).

Preparation.—By reduction of a solution of acetone-phenyl-hydrazide (1 pt.) in 96 p.c. alcohol (10 pts.) by means of acetic acid (24 pts.) and sufficient '67 p.c. sodium-amalgam, the temperature being kept below 25°; the yield is 70 p.c. of the theoretical (Tafel, B. 19, 1926).

Properties .- Mobile liquid, with ammoniacal smell, miscible with water. Converted by nitrous

acid into isopropyl alcohol. Salts. — B'HCl. [1 [140°]. Deliquescent

Satts. — B Dick. [140]. Defiquescents cubes.—B'₂H.PtCl₆: orange plates, m. sol. Aq.

Nitramins PrNH.NO₂. [-4°]. (91°).

PrNK.NO. Slender hygroscopic needles.—
PrNAg.NO. Thin plates. Converted by PrI

Fring.No. Thin plates. Converted by PrI into PrNPs.No. (67° at 10 mm.).

Di-n-propylamine Pr.NH. (110°) (P.; C.); (98°) (V.). S.G. 12. 7480; 23. 7857 (Perkin, C.J. 55, 698). M.M. 7, 549. µ. = 1.4088 (Gladstone, C. J. 59, 290). A product of the action of alcoholic Mil. on Pri at 100° (Vincent, C. R. 103, 208;

190° (Malbot, C. R. 105, 575). Purified by means of its nitrosamine. Liquid with ammoniacal smell, sl. sol. water. The pps. that it forms with salts of Ag and Al are sol. excess; those with salts of Cu and Zn are insol. excess.

Salts.—B'H.C.O. Flat needles. S. 5 at 17°. S. (alcohol) 33 at 18° (Chancel, Bl. [3] 7, 406). Picrate. [75°]. S. 2.2 at 19°. Melts under water at 45°.

Nitrosamine Pr.N.NO. (206°). S.G. & 931. Liquid smelling like hay. Decomposed by HClAq, with formation of dipropylamina

Nitramine PraN.NO. A liquid, got from PrNK.NO, and PrBr (Thomas, R. T. C. 9, 79).

Di-isopropylamine Pr.NH. (84°), S.G. 22 '722. A product of the action of alcoholic NH, on PrI at 100° (Van der Zande, R. T. C. 8, 202; on Fr at 100° (Van der Zande, R. T. C. 8, 202; cf. Siersch, Z. [2] 5, 145). Liquid with very ammoniacal offour, miscible with water. — B'MNO₂. [138°].—B'₂H.PtCl₂: orange tables. Nitrosamine Pr.N.NO. [46°]. (195°). Nitramine Pr.N.NO. [56° at 10 mm.).

Formed from PrNAg.NO, and PrI (Thomas, R. T. C. 9, 82). Liquid.

Tri-n-propylamine Pr. N. (157°). S.G. 9 .770; 15, 760; 25, 754 (Ferkin). S.V. 2221 (Zander, A. 214, 171). M.M. 11·664. $\mu_0 = 1\cdot4171$ (Gladstone, C. J. 59, 290). C.E. (0'-10°) ·00105. A product of the action of Prl on alcoholic NH, V.). It is the chief product got by heating PrCl with cone. NH, Aq (Malbot, A. Ch. [6] 13, 480, 546). Purified by means of its picrate (Chancel, Bl. [3] 7, 407). Liquid with faintly ammoniacal odour, almost insol. water. Pierate. S. 3 at 18; S. (94 p.c. alcohol) 4.4 at 19°.

Propylo-iodide Pr.NI. The chief product of the action of PrI on NH,Aq at 150°-190°. Prisms. Yields (Pr.NCl) PtCl, and deliquescent Pr. NOH, which is decomposed by heat into Pr.N, propylene, and water (Roemer, B. 6,

References .- BROMO-, CHLORO-, CHLORO-10DO-, and Oxy. PROPYLAMINE.

PROPYL-ISOAMYL-GLYOXALINE

C₆H₅(C₅H₁₁)N₂. Oxalisoamyl-butyline. (251°). S.G. ¹² 920. Formed from propyl-glyoxaline and CaH, I (Rieger, M. 9, 609).

PROPYL ISOAMYL OXIDE Pr.O.C.H ... (125°-130°) (Chancel, A. 151, 305).

PROPYL-ANILINE CoH13N 6.6. PhNHPr. (222° i.V.) (Pictet a. Crépieux, B. 21, 1111). S.G. 14° 949. Formed by heating aniline with PrBr (Claus a. Roques, B. 16, 909; Wacker, A. 243, 290). Liquid. Salts.—*B'HCl. [150].— *B'₂H₂C₂O₄. [152°]. Large tables, v. sol. water. Formyl derivative PhNPr(CHO). (269°

i.V.). S.G. 16 1.044. Got from formanilide and n-propyl bromide.

Acetyl derivative PhNPrAc. [48 (269° i.V.). Hexagonal plates (from ligroin).
Nitrosamine. Yellowoil.

Isopropyl-aniline Isopropyl-aniline PhNHPr (213° 1.V.). Liquid. Yields an oily nitrosamine.—B'.H.PtCl... Red prisms (P. a. C.).

Formyl derivative PhNPr.NO. (264°LV.). Formed from formanilide and PrBr.

Acetyl derivative PhNPrAc. [89°]. (265 i.V.). Transparent leaflets (from ligroin).

Di-n-propyl-aniline NPhPr₂. (245° i.V.): S.G. § 9240. S.V. 2431 (Zander, A. 214, 168). (245° i.V.): O.E. (0°-10°) 00081. Formed from aniline and Pri (Lippmann a. Fleissner, M. 3, 711).—
B'_H_PtCl₆. Decomposed by water.

Di-isopropyl-aniline NPhPr₂. (220° i.V.). S.G. 2 9338. S.V. 235.4 (Zander). C.E. (0°-10°) (220° i.V.).

.00087.

References .- NITRO- and NITROSO- PROPYL-AWILINE.

DI-PROPYL-ANTHRACENE DIHYDRIDE

C₂₀H₂₄ i.e. C₆H₄ < CPr₂ < C₆H₄. Formed from dipropyl-anthrone, HI, and P at 140°-170° (Hallgarten, B. 22, 1070). Plates, getting soft at 47°. Di-isopropyl-anthracene dihydride

 $C_eH_aPr < CH_2 > C_eH_3Pr$. [90°]. (above 360°). Formed by boiling C_cH₄Pr.CH₂Cl alone or with ZnCl₂ (Errera, G. 14, 280). Antorphous yellow powder, insol. alcohol, sol. ether. Its solutions are red with green fluorescence.

PROPYL-ANTHRANOL. Propyl derivative. $C_{20}H_{22}O$ i.e. $C_{u}H_{4} < \stackrel{CPr}{C(OPr)} > C_{u}H_{4}$. [72°]. Formed by boiling anthranol with KOHAq and Pri (Hallgarten, B. 22, 1070). Needles, sol. ether and alcohol, insol. alkalis. Chromic acid ether and alcohol, insol. alkalis. solution converts it in the cold into propyloxanthranol C, H16O, [164°], v. sol. benzene.

DI-PROPYL - ANTHRONE C20H22O C.H. CO CPr. C.H. [124°]. Formed, together with the preceding body, by boiling anthranol (5 g.) with KOH (5 g.), water (25 c.c.), and PrI (13 g.) (Hallgarten, B. 22, 1069). Trimetric crystals, sol. hot alcohol. CrO₃ in HOAc oxidises it to anthraquinone.

TRI-PROPYL-ARSINE v. vol. i. p. 319. PROPYL-BENZENE v. CUMENE.

Di-n-propyl-benzene C₆H₄Pr₂[1:4]. Formed from p-di-bromo-benzene, n-propyl bromide, and Na (Körner, B. 11, 1863; A. 216, 223). Formed also, together with the m-isomeride, by the action of AlCl, and HCl on n-cumene (Heise a. Töhl, A. 270, 165). Liquid, volatile with steam. Bromine forms C.H.Br.Pr. [48°].

C.H.PrPr[1:4]. n-iso-Di-propyl-benzene (212° cor.). S.G. º ·8713. Formed from C_sH₄Pr.CH₂Cl and ZnEt₂ (Paterno a. Spica, B. 10, 1746) and from PrBr, p-bromo-cumene, and Na. Formed also, together with the m- isomeride, by the action of AlCl, at -2° on a mixture of π -cumenc and PrBr (Heise, B. 24, 772).

m-Di-isopropyl-benzene CoH4Pr2[1:3]. (204°). Formed, together with the p- isomeride, by the sotion of propyl or isopropyl chloride on benzene in presence of AlCl, (Silva, Bl. [2] 43, 320; Uhlhorn, B. 23, 3142) and by the action of AlCl, and HCl at 100° on cumono (H. a. T.). Yields isophthalic acid on oxidation.

p-Di-isopropyl-benzene C_eH₄Pr₂[1:4]. (c. 202⁵). Formed as above. Yields terephthalic scid on oxidation.

PROPYL-BENZENE SULPHONIC ACID . CUMENE SULPHONIC ACID.

p-M-n-propyl-benzene sulphonic acid C.H.Pr., SO.H. [62°]. Formed from di-propyl-benzene and fuming H.SO. (Körner, B. 11, 1865; 4. 216, 224; Remsen, Am. 5, 162). Deliquescent

needles, with pearly lustre.-NaA'4aq.-KA'4aq. -BaA'₂ ½aq. — BaA'₂ 2aq. — CaA'₂ 9aq. — PbA'₂ aq. Amide C₈H₃Pr₂SO₂NH₂. [103°]. Hexagonal crystals (from alcohol), sl. sol. hot water.

n-iso-Di-propyl-benzene sulphonic acid

[1:4:x] C₈H,PrPr.SO,H. [60°]. Needles (Heise, B. 24, 771). –BaA'₂xaq. –PbA'₂aq: minute needles, m. sol. cold water. –PbA'₂8aq: needles.

Amide. [96°]. Needles.

m-Di-isopropyl benzene sulphonic acid C.H. Pr. SO.H [1:3:x]. Formed by shaking with H.SO, (11 pts.) the fraction (200°-210°) got by the action of AlCl, on a mixture of PrCl and benzene, and separated from the accompanying p-di-isopropyl-benzene sulphonic acid by means of its Ba salt (Uhlhorn, B. 23, 3142). - BaA'22aq: A mide C_uH₃Pr_xSO_xNH_x. [145°].

p-Di-isopropyl-benzene sulphonic acid

C,H,Pr,(SO,H) [1:4:2]. Formed as above.— BaA',: nodules, v. sol. water.—CuA', 0\frac{1}{2}aq. A mide C,H,Pr,SO,NH, [102']. m.Di.n-propyl-benzene disulphonic acid

C_aH_aPr₂(SO₃H)₂. Deliquescent tables (Heise).— K_aA''xaq.—BaA'' 1½aq: tables, v. sol. water.— PROPYL-BENZOIC ACID v. Cuminic Acid.

PROPYL-BENZOYL-ACETIC ACID v. Benz-OYL-ACETIC ACID and PHENYL BUTYL KETONE CARBOXYLIC ACID.

PROPYL-BENZYL- v. CUMINYL-.

n-PROPYL BORATE (PrO), B. (172°-175°). S.G. 12 ·867 (Cahours, C. R. 76, 1383).

Isopropyl borate (PrO), B. (140° cor.). Formed by heating B,O, with isopropyl alcohol at 120° (Councler, J. pr. [2] 18, 389). Mobile oil, slowly saponified by water.

n-PROPYL BROMIDE PrBr. (71°). S.G. 8 propyl alcohol and HBr (Linnemann, A. 161, 40; Pierre a. Puchot, J. Ph. [4] 13, 9). When heated in scaled tubes at 280° it partially changes to isopropyl bromide (Aronstein, R. T. C. 1, 134). When heated for a short time with AlBr, it is completely changed to isopropyl bromide (Kekulé a. Schrötter, B. 12, 2279; Gustavson, J. R. 15, 61). Bromine forms propylene bromide. — C₃H,Br(H₂S)₂23aq (Do Forerand, A. Ch. [5] 28,

Isopropyl bromide PrBr. (60°). S.G. § 1-3397 (Z.); № 1-3097 (B.); ‡ 1-3198; 25 1-3058 (Perkin). C.E. (0°-10°) -00127. μ_S = 1-4317. R_∞ 38·58 (Brühl). M.M. 7-003 at 17·1°. S.V. 99. Formation.—1. From isopropyl alcohol and

HBr at 150° (Linnemann, A. 136, 41).-2. From n-propyl bromide and AlBr. -3. From propylene bromide and HI (Linnemann, A. 161, 57).

Preparation.-By adding bromine (65 g.) gradually to PrI (100 g.) in the cold; the yield being 45 g. (R. Meyer, J. pr. [2] 34, 105).

Properties .- Liquid, not attacked by Cl. ISOPROPYL-BUTENYL-BENZENE v. Bu-

TENYL-CUMENE. n-PROPYL-ISOBUTYL-AMINE C.H., N

PrNH.C.H., (124°). Formed by reducing iso-butyl-propargyl-amine in alcoholic solution with

sodium (Paal a. Heupel, B. 24, 3048).—B'HCl. [185°].—B'H.C.O. [224°]. Needles. ISOPROPYL-BUTYL-AMINE DICARB-

OXYLIC ACID C.H., NO, i.e.

CO.H.CMe, NH.CMe, CH, CO.H. A product of the oxidation of triacetonamine with chromic acid mixture (Heintz, A. 198, 69). Crystalline grains, m. sol. hot water. Yields amido-iso-butyrio acid when heated. — H.A"HCl. — KHA" 2aq. — Zn(HA"), 6aq. — ZnA" aq. — CuA" aq. — Ag. HA". — Ag. A"HNO, aq: grains. PROPYL-ISOBUTYL-GLYOXALINE

(241° at 738 mm.). S.G. 18 .915. Formed from isobutyl-glyoxaline and PrBr (Radziszewski a. Szul, B. 17, 1295). Liquid.— B'aH.PtCla: minute orange prisms.

Propyl-butyl-glyoxaline CH.N:CPr CH.N:(C,II,y).

(243°) at 728 mm. S.G. 12 938. Formed from propyl-glyoxaline and butyl iodide. Oxidised by H.O., to butyl-oxamide [198°] (Rieger, M. 9, 609). -B'HZnCl, -B',H,CdCl, -B',H,PtCl,

Propyl-isobutyl-glyoxaline (H.N:CPr CH.N(C.H.)) (232°) at 736 mm. S.G. 13 .940. Formed from

propyl-glyoxaline and isobutyl iodide (Rieger). PROPYL ISOBUTYL KETONE Pr.CO.C.₁H_y. (155°) at 750 mm. S.G. ^o. 831. Formed from isovaleryl chloride and ZnPr2 (Wagner, J. R. 16,

668). Liquid.

Isopropyl isobutyl ketone Pr.CO.CH.Pr. (160°). S.G. 12 865. Formed by oxidising secoctyl alcohol with cold dilute K.Cr.2O, and H.SO. (Williams, C. J. 35, 130). Liquid, not solid at -17°. Does not form a crystalline compound with NaHSO3

PROPYL-ISOBUTYL-MALONIC ACID

C₄H₉.CPr(CO₂H)₂. [129°]. This appears to be the composition of the acid got by saponifying C,H,C(C,H,)(CO,Et), (219), which is got from malonic ether, isobutyl iodide, allyl iodide, and NaOEt (Ballo, B. 14, 335)

PROPYL BUTYL OXIDE Pr.O.C.H., (117°). S.G. 9 .7773. C.E. (0°-10°) .00124. S.V. 174.4

(Dobriner, A. 243, 7). ISOPROPYL-ISOBUTYL-PHOSPHINE

PHPr.CH, Pr. (140°). Formed from isopropylphosphine and isobutyl iodide at 130° (Hofmann, B. 6. 300).

ISOPROPYL-ISOBUTYL-QUINOLINE

C.H.CPr N=C.CH.Pr. (296°) at 710 mm. Formed by the action of isovaleric aldehyde and conc. HClAq upon aniline (Spady, B. 17, 1718; 18, 8378).—B',H.PtCl, Yellow needles, sl. sol. 8373).—B'.H.PtCl. Yellow needles, sl. sol. water.—B'C.H.(NO.),OH. Large yellow plates. - B'HCl aq. - B'HNO, aq. - B'H.SO,. B'H.Cr.O.: orange needles, sol. hot water.

B'Mel aq. Methylo-iodide Yellow needles, v. sol. alcohol.-B'2Me,PtCla: yellowish-

red triclinic prisms

PROPYL TRICARBALLYLIC ACID

CHPr(CO,H).CH(CO,H).CH2.CO2H. Formed by saponifying its ether, which is made by the action of fumaric ether on sodium propylmalonic ether (Auwers, B. 24, 311, 2898). Prisms (containing xaq), v. c. sol. ether.

Ethyl ether Et,A". (206° at 16 mm.). B.G. Y 1 092,

Isopropyl-tricarballylic acid

CHPr(CO,H).CH(CO,H).CH,CO,H. [162°]. Prepared in like manner from isopropyl-malonic ether. Plates or prisms, v. sl. sol. ligroin.

Ethylether Et.A'". (206° at 20 mm.).

S.G. 19 1.085.

PROPYL CARBAMATE NH...CO.OPr. [52°]. (195°). Formed by heating ures with propyl alcohol (Cahours, C. R. 76, 1387). Formed also from Cl.CO, Pr and NII, (Roemer, B. 6, 1102). Prisms, v. e. sol. water and alcohol.

Isopropyi carbamate NH, CO.OPr. Formed from Cl.CO, Pr and dry NH, (Spica a. Varda, G. 17, 165). Hygroscopic needles.

Varda, G. 17, 165). Hygroscopic needle ISOPROPYL-CARBAMINE PrnC. S.G. 2.760. Formed from isopropyl iodide and AgCy (Gautier, C. R. 67, 723; A. 149, 155). HClAq forms isopropyl-formamide.

PROPYL-CARBAMIC ACID NHPr.CO.H.

Methyl ether MeA'. (180° at 755 mm.).

S.G. 15: 992. Liquid (Thomas, R. T. C. 9, 71).

The nitramine NPr(NO.), CO.Mo. S.G. 15

1.187 is made from NAgPr(NO.) and Cl.CO.Me. Ethyl ether EtA'. (1869). Formed from propylamine and chloro-formic ether (Schreiner,

J. pr. [2] 21, 125).

Isopropyl-carbamic acid NHI'r.CO.II. Methyl ether MeA'. (165.5°). S.G. 14 981. Liquid. The nitramine

NPr(NO.).CO.Me S.G. 14 1:159 is also liquid. PROPYL-CARBINOL v. BUTYL ALCOHOL.

Di-propyl-carbinol v. HEPTYL ALCOHOL.

DI-PROPYL-CARBOBENZONIC ACIDS $C_{2a}H_{\infty}O_{2a}$. Two acids of this formula [139°] and [90°] are formed by heating phenyl bonzyl ketone with n-propyl alcohol and KOH (Zagu-

meany, A. 184, 166). The acid [189°] forms a di-nitro- derivative [176°]. PROPYL CARBONATE CO(OPr)... cor.). S.G. 12 949 (Roese, A. 205, 230).

Propyl orthocarbonate C(Olr), (224° cor.). S.G. 2 911. Formed from NaOPr and chloropicrin (Roese, A. 205, 253)

n PROPYL CHLORIDE PrCl. Mol. w. 783. (46° i.V.). S.G. § 9123 (Zander, A. 214, 156); $\frac{2}{3}$ ° 8898 (Brühl, A. 200, 179), $\frac{1}{3}$ ° 8930; $\frac{2}{3}$ 5813 (Perkin). M.M. 5-056 at 16°. $\mu_B = 1$ 3934. $R_{\infty} = 33$ 36. S.V. 91-6. H.F.p. 37,760. H.F.v. 36,020. C.E. (0°-10°) 00137. Formed by the action of chlorine on propane and on PrI. Prepared by saturating n-propyl alcohol with gaseous HCl, and heating at 125° with conc. HClAq (Malbot, Bl. [3] 2, 136; cf. Pierre a. Puchot, A. Ch. [4] 20, 234). Acts with extreme slowness on alcoholic NH, (Vincent, Bl. [2] 45, 504). Not changed to PrCl by heating in scaled tubes (Aronstein, R. T. C. 1, 134).—PrCl(H_xS)₂ 23aq (De Forerand, A. Ch. [5] 28, 34).

Isopropyl chloride PrCl. (36°). S.G. 3 8825 (Z.); 13 8688; 29 8575 (P.). M.M. 5159 at 17·2°. S.V. 94. C.E. (0°-10°) 00142. Formed from isopropyl alcohol and HCl. Chlorine converts it into CH_CCl_CH_and CH_CHC.CH_CL. Partially converted into NH.Pr by heating with conc. NH.Aq at 140° (Malbot, C. R. 111, 650), ISOPROPYL CINNAMIC ACID v. CUMYL-

ACRYLIC ACID.

References .- AMIDO-, CHLORO-, and NITRO-PROPYL-CINNAMIC ACIDS

PROPYL-m-CRESOL C.H.MePr.OH. (230°-235° at 734 mm.). Formed, together with its propyl ether and di-propyl-m-cresol, by heating m-cresol with propyl alcohol and MgCl. (Mazsara, G. 12, 187, 332). Liquid, sl. sol. water, sol. alcohol and ether. Not solid at -15° . Not coloured by FeCl. Yields a crystalline nitrosoderivative [140°].

Methyl ether MeA'. (226°) at 740 mm. Propyl ether PrA'. (235° 240°). Acetyl derivative AcA'. (240°) at 743

Isopropyl-m-cresol CoH3PrMe.OH. (238°). Formed in like manner by heating m-cresol with isopropyl alcohol and MgCl₂ (Mazzara, G. 12, 505). Oil. Yields C₂H₂(NO)PrMe.OH [167°].

Methyl ether MeA'. (215°-220°).

Isopropyl ether PrA'. (230°-235°).

Isomeride v. THYMOL.

Propyl-o-cresol v. Carvacrol and Cymenol. Isopropyl-cresol CaHaPrMe.OH. (229° cor.). S.G. 2 1 0012. Formed by potash-fusion from the m-isocymene derived from camphor (Spica, G. 12, 552). Not coloured by FeCl.

Ethyl ether EtA'. (228° cor.)

Di-propyl-m-cresol C.H.Pr.Me.OH. (250°). Formed as above. Liquid, yielding a liquid acetyl derivative (255°-260°).

Di-isopropyl-m-cresol C.H.Pr.Me(OH). (251°). Formed at the same time as isopropylm-cresol (M.). Liquid smelling like phenol, sl. sol. water, insol. dilute potash.

Methyl ether McA'. (243°)

Acetyl derivative AcA'. (255°-260°) ISOPROPYL-CUMIDINE

C.H.Pr.NHPr. (245°-250°). A product of the action of aniline and ZnCl₂ on isopropyl alcohol (Louis, B. 16,

111). Liquid. Forms a granular picrate.

180PRUPYL CYANATE v. vol. ii. p. 315.

PROPYL CYANIDE v. Nitrile of BUTYRIO

PROPYLENE C.H.. Mol. w. 42. S. 44 at 0°; 22 at 20° (von Than, A. 123, 187). S. (alcohol) 13. S. (H.SO.) 200 (Berthelot). H.F.p. 8,220. H.F.v. 2,060 (Thomsen, Th.).

Formation.-1. By passing fusel oil, valeric acid, or light petroleum through a red-hot tube (J. W. Reynolds, A. 77, 118; Prunier, J. 1873, 847).—2. By distilling calcium oxalate with KOAc (Dusart, A. 97, 127).—3. By the action of mercury (containing a trace of zine) and fuming HClAq on allyl iodide (Berthelot a. De Luca, A. 92, 306).—4. Mixed with H (\frac{1}{3} vol.), by reducing allyl iodide in alcoholic solution with granulated zinc and HClAq (Tollens a. Henninger, A. 156, 156).-5. From allyl iodide and HI (Butlerow, A. 145, 271).—6. A product of the action of ZnEt, on CCl, (Rieth a. Beilstein, A. 124, 242) on allyl iodide (Wurtz, Bl. 5, 51) and on CHBr, (Beilstein, Bl. [2] 2, 51).—7. By boiling n- or iso-propyl iodide with alcoholic potash (Freund, M. 8, 633; Erlenmeyer, A. 139, 228).—8. Together with other hydrocarbons, by treating propylene bromide with water and sodiumamalgam or with zine and HClAq (Prunier, C. R. 76, 98).-9. By heating CCl, Me, or CBr, Me, with Na at 140° (Friedel a. Ladenburg, Z. 1868, 48; Reboul, A. Ch. [5] 14, 488).—10. Together with cresol, by heating thymol with P₂O₃ (Engelhardt a. Latschinoff, Z. 1869, 616).—11. In the manufacture of oil-gas (Armstrong, C. J. 49, 74). 12. Together with ethylene, by heating allyl alcohol with P₂O₄ (Béhal, A. Ch. [6] 16, 860),— 18. By heating N(C,H,), with C,H,Cl at 190° (Malbot, A. Ch. [6] 13, 546).

Preparation.—1. By dropping propyl alcohol on strongly-heated ZnCl, (Le Bel a. Greene, Am. 2, 23).-2. By passing gaseous HI into allyl iodide, PrI being also formed (Malbot, C. R. 107. 114; Bl. [2] 50, 449) .- 3. By pouring an alcoholic solution of allyl iodide on zinc (Gladstone a. Tribe, B. 6, 1550; Niederist, A. 196, 358).—
4. By dropping propyl alcohol (4 pts.) on P₂O₈ (3 pts.) (Beilstein, B. 15, 1498).-5. By mixing isopropyl alcohol (200 g.) with ZnCl, (650 g.) and heating after twenty-four hours (Friedel a. Silva. J. 1873, 322).

Properties.—Colourless gas, liquefied by pressure of eight atmospheres (Moltschanoffsky, J. R. 21, 31). Unites with Cl and Br. Its solution in H.SO, yields isopropyl alcohol on distilling with water. Cuprous chloride in HClAq absorbs it somewhat. HClAq heated with propylene for seventy hours at 100° forms isopropyl chloride (Berthelot, A. 104, 184); HBr and HI act in like manner. Dilute CrO_2 forms acetone acetic acid and CO_2 (Berthelot, A. 150, 373). Alkaline KMnO, forms formic and acetic acids (Truchot, C. R. 63, 274). KCl added to a solution of propylene in PtCl, and HClAq ppts. CaHaPtClaKCl aq (Birnbaum, A. 145, 72).

Di-propylene v. HEXYLENE.

DI - BROMO - IODO-References. - Bromo. CHLORO-, CHLORO-IODO-, DI-CHLORO-NITBO-, and IODO- PROPYLENE.

PROPYLENE-ACETOACETIC ACID v. ACETO-ACETIC ACID and METHYL TRIMETHYLENYLMETHYL KETONE CARBOXYLIC ACID.

PROPYLENE-ALLYL-4-THIO-UREA

CH₂N(C₃H₅)>C:NH. Formed from propyleneψ-thio-urea and allyl iodide (Hirsch, B. 23, 973). Oil.-B'C_eH_aN₃O_r. [120°]. Triangular prisms.

Isomeride CHMe.S C:NC_aH_a. [56°]. Got

from \$B-bromo-propyl-amine and mustard oil. Prisms (from ligroin).—B'C₅H₄N₄O₇. [130°].—B'C₃H₄NCS. [52°]. White prisms.

PROPYLENE-DIAMINE C₃H₁₀N₃ i.e. S.G. 15 ·878. CH₃.CH(NH₂).CH₂.NH₂. (119°). S.G. 15 878. Formed by heating propylene bromide with alcoholic ammonia at 100°-150° (Hofmann, B. 6, 308; Strache, B. 21, 2358). Hygroscopic liquid, fuming in the air. Yields a hydrate $(C_3H_{10}N_2)_2$ aq, boiling at the same temperature as the base, and dehydrated by Na. Benzoic aldehyde forms oily C₃H₆(N:CHPh)₂, decomposed by HCl into the parent substances. Acetoacetic ether forms oily C_zH_e(NH.CMe:CH.CO₂Et)₂.

Salts.—B'H.Cl., [220]. Very hygroscopic needles.—B'H.PtCl., Small four-sided tables. Acetyl derivative C.H. (NHAc), [139°].

Needles, v. e. sol. water and alcohol.

Benzoyl derivative C.H.Bz.N. [1980]. PROPYLENE-AMYL-4-THIO-UREA

CHMe.S C.NHC, H₁₁, [32°], (267°), Formed by heating allyl-amyl-thio-ures with conc. HClAq at 100° (Avenarius, B. 24, 264).

PROPYLENE BROMIDE v. Dr.BROMO-PRO-

PROPYLENE TRICARBOXYLIC Ethyl other CO.Et.CH;CH.CH(CO.Et),. (1710.

FROPYLENE BULPHUUTANIDE.

at 15 mm.). Formed by the action of water or of NaOHAq upon $CH \leqslant C(CO,Et).C(OEt) > O[94°]$, which is got by distilling di-carboxy-glutaconic ether in vacuo (Guthzeit a. Dressel, B. 22, 1425). It is identical with iso-aconitic ether.

Isomeride v. Aconitic acid.

Propylene tetra-carboxylic acid (CO2H)2CH.C(CO2H):CH.CO2H. [192°]. Got by saponifying its ether. Colourless crystals (containing 2aq). Gives off CO, at 180°.

Salts. - Na HAiv Sag. - Ba Aiv 11 ag. -Ca,Aiv 3 aq.

Ethyl ether Et, Air. (220°-230° at 40 mm.). Formed from sodium-malonic ether and bromo-maleïc ether (Schacherl, A. 229, 91).

Isomerides .- DICARBOXY-GLUTACONIC ACID and TRIMETHYLENE TETRACARBOXYLIC ACID.

PROPYLENE CHLORHYDRIN v. Chloro-PROPYL ALCOHOL. PROPYLENE CHLORIDE v. DICHLORO-

PROPANE.

PROPYLENE CHLOROBROMIDE v. CHLORO-BROMO-PROPANE.

PROPYLENE GLYCOL CaHaOai.e. CaHa(OH)2.

Formation.—1. By saponifying its acetylderivative (Wurtz, A. Ch. [3] 55, 438).—2. By reduction of CH,Cl.CH(OH).CH OH by sodiumamalgam (Lourenco, C. R. 52, 1043) .- 3. By heating propylene bromide with PbO and much water at 150° (Eltekoff, J. R. 10, 210).-4. By boiling propylene bromide with aqueous K.CO, for some days (Hartmann, J. pr. [2] 16, 383). 5. By boiling propylene bromide (1 pt.) with water (36 pts.), the yield being 43 p.c. (Niederist, A. 196, 359).-6. By the action of the copperzine couple and some HClAq on the product of the action of AcBr on glycerin (Hanriot, C. R. 86, 1139) .- 7. By treating allyl alcohol with dilute H.SO. (20 p.c.) or HCl (10 p.c.) (Solonina, Bl. [2] 46, 816).

Preparation. - Glycerin (1,300 g.) is distilled with NaOH (550 g.) and the aqueous layer concentrated and distilled; the yield is 140 g. (Belohoubek, B. 12, 1872; Morley a. Green, C. J. 47, 182).

Properties. - Liquid, with sweet taste; miscible with water and alcohol.

Reactions .- 1. Water containing a trace of HCl forms propionic aldehyde at 215° (Linnemann, A. 192, 61). It also yields propionic aldehyde on heating with ZnCl. (Flavitzky, B. 11, 1256). -2. Conc. HIAq forms isopropyl iodide (Wurtz, A. Suppl. 1, 381) .- 8. PCl, forms dichloro-propane.—4. KOH at 250° forms oxalic acid and H.—5. Chromic acid mixture forms acetic acid (Flavitzky, B. 11, 1256).-6. Oxidised by platinum black and air to lactic acid.-7. Glyceryl trimetric forms, at 100°, oily CH, CH(O.NO).CH, O.NO (109°), S.G. 2 1.44, which explodes in sunlight (Bertoni, C. C. 1887, 85).

Acetyl derivative C,H,,O, i.e. C.H. (OAc). Propylene acetale. (186°). S.G. 21:109. S. 11. Formed by heating C.H. Br. with AgOAc and HOAc (Wurtz, A. 105, 202). Neutral liquid.

Mono-bensoyl derivative CH, CH(OBz).CH, OH. Formed from the amine CH, CH(OBz).CH, NH, and HNO, (Gabriel a. Heymann, B. 23, 2501). Oil.

Di bensoyl derivative

Liquid (Friedel a. Silva, C. R. 78, 1879).

Di-nitrate C.H. (O.NO.). S.G. 1835.

Formed by dropping propylene oxide into strongly-cooled fuming HNO. (Henry, A. Ch. [4] 27, 261). Oil.

Chlorhydrin v. CHLORO-PROPYL ALCOHOL.

Bromhydrin v. BROMQ PROPYL ALCOHOL.

Iodhydrin C,H,I(OH). (105° at 60 mm.). Formed from propylene oxide and HI (Markownikoff, Z. 1870, 423). Liquid.

Active propylene glycol $C_3H_6(OH)_2$, $\alpha_0 = -4^\circ 35'$ to $-1^\circ 15'$ in a 22 mm, tube. Formed, together with propionic and lactic acids, by allowing Bacterium termo to breed in ordinary inactive propylche glycol (Le Bel, C. R. 92, 532). Yields active propylene oxide (35°) $a_D = +1° 10°$ in a 22 mm. tube.

n-Propylene glycol v. TRI - METHYLENE GLYCOL

PROPYLENE IODIDE v. DI-10DO-PROPANE. Di-oxy-propane. Mol. w. 76. (189°). S.G. 3 PROPYLENE MERCAPTAN C₃H₀(SH)₂. 10527 (Z.). C.E. (0°-10°) 00069. S. (ether). (152° in vacuo). Formed by reducing propylene sulphocyanide with Zn and HClAq (Hagelberg, R = 23 - 1087

PROPYLENE OXIDE C.H.O i.e.

CHMe O. Mol. w. 58. (35°). S.G. 2 859. V.D. 2.0. Formed by warming propylene chlorohydrin with KOHAq (Oser, Bl. 1860, 237; Morley, B. 15, 179). Dried over KOH. Neutral liquid, smelling like acctone. Miscible with water, alcohol, and ether. Reduced by sodium-amalgam to isopropyl alcohol. Yields acetic acid when oxidised by moist Ag.O (Linnemann, M. 6, 869)

PROPYLENE-OXIDE CARBOXYLIC ACID v.

METHYL-GLYCIDIC ACID.

PROPYLENE PHENYL ETHYL KETATE CHMe.O CPhEt. (235° cor.). S.G. 22 .988. Formed by dropping CaHaCl.OBz into a mixture of ZnEt, and toluene, and then adding water (Morley a. Green, C. J. 47, 134; B. 17, 8015). Oil, with pleasant odour; sol. ether. Not on, with pleasant odour; soil etner. Not attacked by alcoholic potash, by AcCl, by Na, by hydroxylamine, by phenyl-hydrazine, or by HClAq at 155°. HI at 200° yields PrI and phenyl ethyl ketone. By dissolving in H.8O₄ and pouring into water, it is split up into w propylene glycol and C_aH₅.CO.C_aH₅. Nitric acid oxidises it to acetic and benzoic acids. Bromine forms a mono-bromo- derivative (230°).

PROPYLENE - PROPYL - 4 - THIO - UREA CHMe.S C.NHPr. [237°]. Formed by heating allyl-propyl-thio-urea with conc. HClAq at 100° (Avenarius, B. 24, 264). Oil.—Picrate [1280].

PROPYLENE SULPHIDE C.H.S. Formed from C3HBr, and alcoholic Na2S (Husemann, 4. 126, 296). Amorphous powder.

PROPYLENE SULPHOCYANIDE C.H.N.S. i.e. CH, CH(SCy).CH, (SCy). Formed by heating C,H,Br, with potassium sulphocyanide and alcohol at 100° (Hagelberg, B. 28, 1086). Insol. water, sol. alcohol and ether.

PROPYLEME DISULPHONIC ACID v. Pro- | [192°].-B',H,C,O, 2aq: [161°]; plates or needles. PANE DISULPHONIC ACID.

PROPYLENE SULPHONIC ACID CH₂:CH.CH₂:SO₂H. Formed by boiling allyl iodide with conc. K₂SO₂Aq (Von Rad, A. 161, 218).—KA'. Crystalline solid.—(KA'),K (KA'),K,I. White solid. PROPYLENE TRI-THIO-CARBONATE Crystalline solid .- (KA'), K.I. .-

C₂H₆;CS₂. S.G. ²⁰ 1.31. Formed from C₃H₆Br₂ and Na₂CS₃ (Husemann, A. 126, 269). Thick

liquid, of disagreeable smell.

PROPYLENE-\(\psi\)-THIO-UREA C₁H_{*}N₂S i.e. CHMe.S C:NH. Imido-methyl-thiazole tetrahydride. Formed by heating allyl-thio-urea with HClAq (8.G. 1-17) under pressure at 100° (Gabriel, B. 22, 2985). Formed also from B-bromo-propyl-amine hydrobromide and po-B'C₄H₃N₃O₇. [200°]. — Mot hylo - iodide [172°], Colourless prisms.

CHMe.O >C:NH. PROPYLENE U-UREA Formed by heating allyl-ures with HClAq at 100° (Gabriel, B. 22, 2990), and by heating \$\beta\$-bromo-propyl-amine hydrobromide with potassium cyanate at 100° (Hirsch, B. 23, 966).-

B'C,H,N,O, [186°]. Needles.—B',H,PtCl,. PROPYL ETHER v. DI-PROPYL OXIDE. PROPYL-ETHYLENE v. AMYLENE.

PROPYL-EUGENOL v. EUGENOL. PROPYL FLUORIDE PrF. (2°). V.D. 2·161 at 20° (calc. 2·175). S. 1 at 15°. Formed by gently warming AgF with PrI (Meslans, C. R. 108, 352). Gas, with ethereal odour and hot, sweet taste. Has no action on glass when dry.

V. sol. alcohol, ether, and benzene. Isopropyl fluoride PrF. (-5°). S. 1.5 at 15°; S. (alcohol) 29 at 16°. V.D. 2.171. Formed from AgF and PrI. Gas, not affected by KOHAq at 100°. Br at 30° forms a liquid (143°), while chlorine forms a liquid (105°).

ISOPROPYL-FORMAMIDE v. Formamide in article on FORMIC ACID.

DI-PROPYL-FURFURANE C,H,Pr,O. (120°). One of the products of the distillation of sodium citrate with lime (Bischoff, B. 23, 1918).

DI-PROPYL-GLUTARIC ACID C,1H20O, i.e. (CO.H.CH.Pr),CH₂. [89°]. Formed by heating ((CO.H),CPr),CH₂ above 170° (Dressel, A. 256, 190). Needles, v. sl. sol. water, v. sol. ether.

PROPYL-GLYCOL v. PROPYLENE GLYCOL. PROPYL-GLYOXAL. Mono orin

C.H., CO.CH:NOH. [51°]. Formed from methyl propyl ketone, amyl nitrite, and HCl or NaOEt (Claisen a. Manasse, B. 22, 528). Pearly plates.

Chaisen a. Manasse, B. 22, 525). Fearly flates,
Di-oxim Pr.C(NOH).CH(NOH). [168°],
Di-phenyl-di-hydraxids
PrC(N,HPh).CH(N,HPh). [163°]. Needles.
PROPYL-GLYOXALINE C.H.,N., (210°–228°). S.G. 19 267. Formed by heating glyoxaline with PrBr (Wallach, B. 15, 650; 16, 534; A. 214, 321). Liquid, miscible with water. HgCl, added to its aqueous solution gives a pp. sol. HOlAq.—B',H,PtCl. Crystals, sol. hot water.

Propyl-glyoxaline CH.NH CPr. Formed from glyoxal, n-butyric aldehyde and NH, (Rieger, M. 9, 603). Oil. — B'₂H₂C₁O₄.

-B'_H.PtCl.: yellow prisms.
Isopropyl-glyoxaline. Glyoxal-isobutyline. [129°]. (c. 250°). Formed from glyoxal and isobutyric aldehyde-ammonia (Radziszewski, B. 16, 747). Needles, sol. alcohol, benzene, and hot water .- B'HCl. [105°] (Rieger) .- B'HBr.

hot water.—B'H.C.O. [195°].

Di-propyl-glyoxaline C₄H,PrN, (227°).

S.G. 12 '939. Formed by heating propyl-gly-

oxaline with PrI (Rieger, M. 9, 607).

n-PROPYL-GLYOXYLIC ACID Pr.CO.CO.H. (180°-185°) at 760 mm.; (115°) at 84 mm. Got by the action of HCl on the nitrile (1330-137°) which is made from AgCy and butyryl chloride (E. Moritz, C. J. 39, 16). Liquid.

Amide C,H,O.CONH,. [10 from the nitrile and conc. HClAq. [106°].

Oxim PrC(NOH) CO.H. [1449]. Formed by the action of alcoholic soda and NaNO, on propyl-acetoacetic ether (Fürth, B. 16, 2180). Small needles, v. sol. alcohol, sl. sol. water.

Isopropyl-glyoxylic acid *Pr.CO.CO.H. mixture (93° at 45 mm.) of this acid with isobutyric acid is got by the action of HCl on diisobutyryl dicyanide (Moritz, C. J. 39, 14).

Amide * Pr.CO.CONH, [126°]. PROPYL HEPTYL KETONE C,H,.CO.C,H,, [12°]. (222°). S.G. 20 828. Formed by distilling calcium butyrate (Limpricht, A. 108, 185).

PROPYL HEPTYLOXIDE ProC, H₁₅. (188°). S.G. § .7987. S.V. 245·6. C.E. (0°-10°) ·00099 (Dobriner, A. 243, 7).

DI - ISO - PROPYL - HEXINYL DIKETONE Pr.CO.C₃H₅:C₃H₅.CO.Pr. Di-isobutyrone. 266°). Formed by the action of sodium on iso-

butyric ether (Bruggemann, A. 246, 151). PROPYL - HEXYL - CARBINOL v. DECYL

PROPYL-HEXYL-GLYOXALINE C.H., PrN., Oxalpropylænanthyline. (286°). S.G. 4. 919. Formed from hexyl-glyoxaline and PrBr (Karez,

M. 8, 222). Oil.
PROPYL HEXYL KETONE Pr.CO.C,H,, [-9.5°]. (207°]. S.G. 21 -824. Formed by oxidation of the corresponding alcohol (Wagner, J. pr. [2] 44, 271). Needles. Oxidised by K.Cr.O. and H.SO. to heptoic and propionic

Isopropyl hexyl ketone Pr.CO.C. H15. (200°-210°). S.G. 17 .841. Formed by distilling calcium isobutyrate with calcium heptoate (Fuchs, J. R. 7, 334). Yields acetone, HOAc, and heptoic acid on oxidation.

PROPYL HYPOPHOSPHATE Pr.P.O. 15 1-134. Formed from Ag.P.,O., and Pri (twice the calculated quantity) at 120° (Sänger, A. 232, 12). Oil. Decomposed by hot water.

Propyl-hypophosphate of barium

PREMIP O See Nordles

PrBaHP, O, 6aq. Needles.
PROPYLIDENE-ACETIC ACID v. PENTENOIC

ISOPROPYLIDENE-AMIDO-PHENOL

CMe,:N.C,H,.OH. [168°]. Formed from p-amido-phenol, acetone, and HOAc (Haegele, B. 25, 2755). Colourless plates.

ISO-PROPYLIDENE-ANILINE C.H.N:CMe. (228°). V.D. 66.4 (calc. 66.5). From acetone and aniline in presence of dehydrating agents (Engler a. Heine, B. 6, 638; Riehm, A. 238, 10). Liquid; rapidly turning brown in air. Its salts are v. sol. water and alcohol. -B', H, SO, : decomposes at 235°.

PROPYLIDENE CHLORIDE v. DI-CHLORO-

PROPANE.

PROPYLIDENE - HYDRAZIDO - BENZENE p-SULPHONIC ACID CMe_:N.NH.C.H.SO.H. Got from p-hydrazido-benzene sulphonic acid (phenyl-hydrazine p-sulphonic acid) and acetone (Pfülf, A. 239, 216). Plates, m. sol. hot water. 180-PROPYLIDENE HYDRAZINE

CMe,:N.NH, (125°). Formed from acctone and hydrazine hydrate (Curtius, J. pr. [2] 44, 543). Mobile liquid decomposing when kept, with evolution of N and NH

ISO.PROPYLIDENE-PHTHALIDE C,1H,0O, i.e. $C_4H_4 < \frac{C(CMe_2)}{CO} > 0$. [96°]. Formed by heating phthalic anhydride with NaOAc and isobutyric acid or pyrotartaric acid (Gabriel a. Michael, B. 11, 1683; Roser, B. 17, 2776). Needles, sl. sol. hot water. Converted by boiling alkalis into Pr.CO.C.H.,CO.H.
DI-ISO-PROPYLIDENE DISULPHONE v.

Tetra-methyl-di-methylene disulphone.

ISOPROPYLIDENE - DI - THIO - DIGLY-COLLIC ACID CMe.(S.CH2.CO.H). [127°]. Formed from thioglycollic acid, acetone, and ZnCl₂ (Bongartz, B. 21, 482). Crystals (from chloroform)

ISOPROPYL INDOLE C, H, N i.e.

 $C_{s}H_{s} < CPr_{NH} > CH$. (288°). Formed by heating the phenyl-hydrazide of isovaleric aldehyde with ZnCl, at 180° (Trenkler, A. 248, 106). Oil, solidifies by cold. Yields a dihydride (c. 260°) and a picrate [99°] crystallising in red needles. Di-isopropyl-indole C, H, N i.e.

CPr:CII.C.CPr CII. [65°]. (295° 300°). Formed CII:CH.C.NH by the action of dilute H SO, on isopropyl-pyrrole in the cold (Dennstedt, B. 21, 3430). Needles (from dilute alcohol). Colours acidified pinewood red. Yields a picrate [115] and an acetyl derivative [186]. Benzoie aldehyde and ZnCl, form C., H., N. [c. 164].

**n-PROPYL 10DIDE C., H., I. (102-5)* (Brown,

Pr. 26, 238). S.G. 21.7829 (Dobriner, A. 243, 24); 10 1 7673; 15 17585 (Perkin); 29 1 7427 (Brühl, A. 203, 15). C.E. (0°-10°) 00105. $\mu_{\rm p}$ 1 5157. R. 4705. M.M. 11 08 at 18°. S.V. 106°9. Formed from propyl alcohol (60 g.), iodine (127 g.), and red P (10 g.), the yield being 90 p.c. of the theoretical amount (Chancel, Bt. [2] 39, 648;

Cf. Linnemann, A. 160, 240). Oil.

Isopropyl iodide PrI. (89°). S.G. 32 1-7033
(Brühl); 15 1-7163; 25 1-7005 (Perkin). M.M.
11-182 at 26°. μ_B1-5108. R_ω 47·48. S.V. 108·3.
Formed by the action of HI on isopropyl alcohol, propylene glycol, glycerin, allyl iodide, or propylene (Linnemann, A. 161, 26; Wurtz, A. Suppl. 1, 381; Erlenmeyer, A. 126, 305; 139, 228; Maxwell Simpson, A. 129, 127; Berthelot, A. 104, 184; Butlerow, A. 145, 275). Prepared A. 104, 164; Butterow, A. 145, 276). Frepared by distilling glycerin (200 g.) with I (300 g.), water (160 g.), and clear phosphorus (55 g. added slowly) in a current of CO₂ (Mar-kownikoff, A. 138, 364; R. Meyer, J. pr. [2] 34, 98). Obtained also by saturating allyl iodide with HI and heating in sealed tubes at 100° (Malbot, C. R. 107, 114; Bl. [2] 50, 449; A. Ch. [6] 19, 352). Oil, converted by Br into PrBr.

The copper-zinc couple decomposes it at 50° giving off gases (Gladstone a. Tribe, C. J. 26.

PROPYL-ITACONIC ACID C.H., O. 4.6. CO,H.CH, C(CO,H):CHPr. [159°]. Formed by heating propyl-paraconic ether with alcoholic NaOEt, and saponifying the product (Fittig, A. 256, 106; cf. Schmidt, A. 255, 83). Tufts of 256, 106; cf. Schmidt, A. 255, 83). Tufts of prisms, insol. chloroform, v. sol. other. Reduced by sodium amalgam to butyl-succinic acid [81°]. Bromine, followed by hot water, gives rise to CHPr< $\stackrel{C(CO_2H)}{O.CO}$ >CH [124°].—BaA".

DI.PROPYL-KETINE ₹. DI-METHYL-DI PROPYL-PYRAZINE.

DI-PROPYL KETONE C,H,O i.e. COPr2. Bulyrone. Mol. w. 114. (145°). S.G. 35 8217; 389). Prepared by distilling calcium butyrate alone or mixed with CaCO, (Chancel, A.52, 295; Kurtz, A. 161, 205; Schmidt, B. 5, 597). Formed also from ZnPr, and butyryl chloride, by the oxidation of di-propyl-carbinol (Schtscherbakoff, J. R. 13, 346), and by heating butyry chloride (1 mol.) with FeCl, (1 mol.) at 50° (Hamonet, Bl. [2] 50, 355). Got also by heating butyric anhydride with sodium butyrate at 180° (Perkin, C. J. 49, 325). It is also one of the products formed by the action of sodium on butyric ether (Brüggemann, A. 246, 140). Oil, sol. alcohol. Does not combine with NaHSO. or NH₃. Chromic acid yields propionic and butyric acids. Treatment with Zn and EtI followed by water gives ethyl-di-propyl-carbinol; while Zn, McI, and water give methyl-di-ethyl-carbinol (A. Saytzeff, J. pr. [2] 31, 320). Sodiumamaigam forms sec-heptyl alcohol and a pinacone C₁₄H₂₀O₂ [68°] (c. 260'). PCl, yields C.H₁₄Cl₂ (181°) and C.H₁₄Cl (141°) (Tavildaroff, B. 9, 1442). Gives on chlorination, when cooled by ice and salt, the compound Pr.CO.CHCl.Et by ice and sait, the compound Pr.CO.CHCi.Ed.

(c. 175°) converted by NH₂ into tetra-propylpyrazine (Vladesco, Bl. [3] 6, 835). P.O. forms

(C,H_{1,2})₂ (200³-250') (Tavildaroff, B. 9, 1442).

Oxim Pr₂C:NOH. (190°-195°) (Meyer a.

Warrington, B. 20, 501). Yields an acetyl

derivative.

 $(124^{\circ}$ Di-isopropyl-ketone Pr.CO. S.G. 2 8230; 20 8063 (Poletical, J. R. 20, 672). H.C. 1,044,559 (L.). R_∞ 33·46. Formed by distilling calcium isobutyrate (Popoff, B. 6, 1255; Münde, B. 7, 1370; A. 180, 327). Formed also by heating tetra-methyl-phloroglucin with HClAq at 200° (Spitzer, M. 11, 288). Oil, with ethereal odour, miscible with alcohol and ether. Does not unite with NaHSO,. Reduces ammoniacal AgNO, Yields isobutyrio and acetic acids and CO, on oxidation, and secheptyl alcohol (c. 140° cor.) on reduction.

Oxim Pr₂C:NOH. [8°]. (c. 183°). Liquid, converted by AcCl into Pr₂C:NOAc, which on heating produces PrCO.NHPr (M. a. W.).

Dipropyl-diketone v. DIBUTYRYL.

Reference. — CHLORO-DI-ISOPBOPYL-KETONE.

PROPYL-LUPETIDINE v. DI-METHYL-PROPYL-PYRIDINE HEXAHYDRIDE.

PROPYL-LUTIDINE v. DI-METHYL-PROPYL-PYRIDINE.

PROPYL-MALONIC ACID C.H.,O. i.s. CHPr(CO.H) Mol. w. 146. [84°] (S.); [96°]

(F.). H.C.p. 675,000. H.C.v. 674,700. H.F.

234,000 (Stohmann, J. pr. [2] 40, 211).

Ethyl ether Et.A". (222°) (Fürth, M. 9, 809). S.G. 15 9931; 25 9854. M.M. 10:367 at 18° (Perkin, C. J. 45, 514). Formed from malonic ether, PrI, and zinc or NaOEt.

Isopropyl-malonic acid CPrH(CO2H)2. H.C.v. 674,900. H.C.p. 675,200. H.F. 233,800 (Stohmann). Formed by saponifying its ether, which is made from sodium-malonic other and PrI (Conrad a. Bischoff, B. 13, 595; A. 204, 144). Prisms, sol. water, alcohol, and ether. Yields iso-valeric acid at 180°.—Ag.A".

Ethyl ether Et.A". (214°). S.G. 10 '997 (C. a. B.); 15 '9927; 25 '9852 (Perkin). M.M. 10 '482 at 17°.

References .- DI-BROMO- and Oxy- PROPYL-

MALONIC ACID.

ISOPROPYL-MALONIC ALDEHYDE NI-TRILE PrCH(CN).CHO. (137°). V.D. 3.83 (calc. 3.87). S.G. 15 911. Formed by heating iodoisovaleric aldehyde with KCy or AgCy (C'autard, A. Ch. [6] 16, 188). Oil which reduces Fehling's solution. Miscible with alcohol and ether.

n-PROPYL MERCAPTAN PrSH. Mol. w. 76. (68°) (Roemer, B. 6, 784 sh Schatzmann, A. 261, 7). Formed from PrBr and alcoholic KSH. Oil, smelling like mercaptan. Hg(SPr).

Isopropyl mercaptan PrSH. (57°-60') (Henry, B. 2, 495; Claus, B. 5, 659; 8, 532). Formed from PrI and alcoholic KSH. Hg(SPr)2: white plates (from alcohol).

PROPYL-METHANE is BUTANE.

Di-propyl-methane v. HEPTANE. DI PROPYL TRIMETHYLENE TRISUL.

PHONE CPr₂ SO₂ CH₄ SO₂. [297°]. Formed

from sodium trimethylene trisulphone and PrI in alcohol (Camps, B. 25, 244). Slender needles, m. sol. boiling alcohol.

Hexa - propyl . trimethylene trisulphone CPr₂ SO₂ CPr₂ SO₂. [133°]. Formed from the trisulphone, PrI, and alcoholic NaOH Prisms. (Camps).

ISO-PROPYL-NAPHTHALENE C13H1, i.c. C₁₀H,Pr. (265°). V.D. 5·85. Formed by heating naphthalene with PrBr and AlCl₃ (Roux, Bl. [2] 41, 379; A. Ch. [6] 12, 289). Oil, sol. alcohol and benzene. Yields (β) -naphthoic acid on oxidation.-B'C,H,N,O,. [90°]. Lemon-yellow

PROPYL NITRATE PrNO, (110.5°) (Perkin, C. J. 55, 683). S.G. 15 1.0031; 22 1.0531. M.M. 4.085. Formed by distilling n-propyl alcohol with HNO, and a little urea (Wallach a. Schulze, B. 14, 420). Forms with anthracene C₁,H₁₀PrNO₃ [92°] crystallising in four-sided prisms (Perkin, jun. a. Mackenzie, C. J. 61, 866).

Isopropyl nitrate PrNO, (102°). S.G. 2 1.054 (Silva, A. 154, 256).

Reference.—Chloro-isopropyl nitrate. PROPYL NITRITE Pro.NO. (43° $(43^{\circ}-46^{\circ})$ (Cahours, C. R. 77, 749); (53°-60°) (Pribram a. Handl, M. 2, 655). S.G. 21 935 (C.); § 998 (P. a. H.). Formed by passing nitrous acid gas into n-propyl alcohol.

(44°). Isopropyl nitrite PrNO, (44°). S.G. 2 *856; 25 844 (Silva, Bl. [2] 12, 227; Kissel,

J. R. 1882, 226).

PROPYL ψ -NITROLE C,H,N,O, i.e. CH, C(NO₂)(NO) CH, Mol. w. 118. [70°] (Bewad, B. 24, 976). Formed by adding KNO₂ and dilute H.SO, to an alkaline solution of isonitro-propane CHMo, NO, (V. Meyer a. Locher, B. 7, 670; A. 175, 120). Monoclinic crystals, insol. water and alkalis. Forms a blue liquid when fused. Its solutions in alcohol and chloro-

form are blue. PROPYL-NITROLIC ACID C.H.N.O. CH3.CH.CH(NO2)NO or CH3.CH.C(NO2):NOH. [60°]. Formed by adding potassium nitrite and dilute H₂SO₄ to an alkaline solution of nitropropane CH₂CH₂CH₂NO₂. Formed also from Et.CBr₂NO₂ and hydroxylamine (V. Meyer, B. 7, 670; 9, 395). Prisms, with sweet taste, v. sol. water, alcohol, and ether. Alkalis form a deep-red solution. Conc. H.SO, forms propionio acid and N.O.

PROPYL OCTYL OXIDE Pr.O.C.H ... (207°

S.G. © 8039. C.E. (0°-10°). ·00101. S.V. 272·4 (Dobriner, A. 243, 7). DI-PROPYL OXIDE Pr₂O. Propyl ether. (90.7° i.V.). S.G. 9.7633 (Zander, A. 214, 163). C.E. (0°-10°) .00125 (Dobriner, A. 243, 20). S.V. 150.9. Formed from PrI and KOPr (Chancel, A. 151, 304). Got also from PrI and Ag₂O (Linnemann, A. 161, 37) and by heating n-propyl alcohol with H.SO, at 135° (Norton a. Prescott, Am. 6, 243).

Di-isopropyl oxide Pr.O. (68.8° i.V.). S.G. (7435. C.E. (0°-10°) (00130. S.V. 151.6 $^{\circ}$ 7435. C.E. $(0^{\circ}-10^{\circ})$ $^{\circ}$ 00130. S.V. 1516 ander). Got from PrI and Ag₂O (Erlenmeyer, (Zander).

A. 126, 306). PROPYL OXYBUTYL KETONE

C3H7.CO.CH(OH).C3H7. Butyroin. (180°-190°). Formed from di-n-propyl diketone and alcoholic KOH (Klinger a. Schmitz, B. 24, 1273). Yields a phenyl-hydrazide | 135°].

PROPYL-PHENOL v. CUMENOT

PROPYL-PHENOL CARBOXYLIC ACID v. OXY-CUMINIC ACID.

Isopropyl-phenol dicarboxylic acid

C.H.Pr(OH)(CO2H)2. [295°]. Formed, together with oxy-cuminic acid, by the action of Na and CO. on isopropyl-phenol (Fileti, G. 16, 126). Tables or needles, sol. water and alcohol.

p-PROPYL-PHENYL-ACETIC ACID C₂H₁.C₆H₁.CH₂CO₂H. [52°]. Formed by saponifying the nitrile, which is got from e-chloro-cymene, alcohol, and KCy at 100° (Rossi, A. Suppl. 1, 139). Small needles (from hot water). - AgA': slender needles.

References .- AMIDO- and OXY-PROPYL-PHENYL-ACETIC ACID.

PROPYL-PHENYL-AMINE v. AMIDO-PHENYL-PROPANE and PROPYL-ANILINE.

ISOPROPYL-PHENYL- v. CUMYL-

ISOPROPYL-PHENYL-CINNAMIC ACID Pr.C.H..C(CHPh).CO.H. [184°]. Formed from Pr.C.H., CH., CO., Na, benzoic aldehyde, and Ac. O (Magnanini, G. 15, 509). Needles (from dilute alcohol).—CaA',.—AgA'.

ISOPROPYL: PHENYL.—COUMARIC ACID.

Methyl derivative

Pr.C.H.,C(CO,H):CH.C.H.,OMe. [199°]. Formed from Pr.C.H.,CH.,CH.,CO,Na, anisic aldehyde, and Ac.O (Magnanini, G. 15, 511). Prisms (from

alcohol).—AgA'. DI-p-PhOPYL - DI - PHENYL - CYANAMIDE C(N.C.H.Pr), [168°]. Formed by heating

CS(NH.C.H.Pr), with benzene and PbO (Francksen, B. 17, 1228). Needles.
PROPYL-BENZONITRILE v. Nitrile of Cv-

MINIC ACID.

ISOPROPYL - DI - PHENYL - ETHYLENE C.H., CH:CH.C.H.Pr. [84°]. Formed by heating phenyl-acetic acid with cuminic aldehyde and NaOAc at 250° (Michael, Am. 1, 314).

Scales (from alcohol), v. sl. sol. hot water.

DI -p - PROPYL - DIPH ENYL - GUANIDINE

NH:C(NH.C₄H₄Pr), [113°]. Formed by heating
di-propyl-di-phenyl-thio-urea with alcoholic NH₄ and PbO (Francksen, B. 17, 1225). Needles, v. sol, warm alcohol and ether .- Platinochloride (C₁₀H₂,N₃) II.PtCl₃: yellowish brown pp. Tri-propyl-tri-phenyl-guanidine

C.H.PrN:C(NH.C.H.Pr). Formed by heating CS(NH.C.H.Pr). with C.H.Pr.NH., alcohol, and Amorphous resin, v. sol. alcohol. -

B'2H2PtCl6: brown powder.

pm.PROPYL-PHENYL METHYL KETONE CH₃.CO.C₆H₄Pr. (259° i.V.). S.G. ¹⁵/₂ 979. Formed from n-cumone, AcCl, and AlCl, (Widmann, B. 21, 2224). Colourless liquid. Yields mann, B. 21, 2224). Colourless liquid. an oxim [540], which melts at 440 after fusion. The phenyl-hydrazide [92°] forms six-sided hatchet-shaped tables.

Isomeride CH3.CO.C6H4Pr. (253°). Yields an oxim [71°] and a phenyl-hydrazide [82°]. ISOPROPYL PHENYL PHOSPHATE

PO(O.C, H, Pr), (375° 380° at 280 mm.). from isopropyl-phenol and PBr, (Fileti, G. 16, 130). Viscid liquid, insol. water, sol. alcohol.

p-ISOPROPYL-(Py. 3)-PHENYL-QUINOLp. 180 FROT IL-(1 y. ... CH; CH; CH; CH; CH; Pr. ... C Formed by heating its carboxylic acid with sodalime (Döbner, A. 249, 102). Needles, sl. sol. water. — B'₂H₂PtCl₃ 2aq. — B'₂H₄Cr₂O₅, — Picrates: [195]; plates (from alcohol).

Carboxylic acid $C_bH_i < \frac{C(CO_2H):CH}{N} = \frac{C.C_0H_iPr.}{C.C_0H_iPr.}$ [201°]. Formed from cuminic aldehyde, pyruvic acid, and aniline (Döbner). Yellow plates (from HOAc). -AgA': white powder.

p-PROPYL-PHENYL-THIOCARBIMIDE C.H.Pr.N:CS. (263°). Formed by heating dipropyl-di-phenyl-thio-ures with syrupy 11,100, (Francksen, B. 17, 1223). Oil, volatile with steam, v. sol. alcohol and ether.

p-PROPYL-PHENYL-THIO-UREA $C_{i0}H_{11}N_2S$ i.e. NH, CS.NH.C.H.Pr. [159°]. Formed from amido-phenyl-propane hydrochloride and ammonium sulphocyanide (Francksen, B. 17, 1222). Needles, sol. alcohol and ether.

Di-propyl-di-phenyl-thio-urea

CS(NH.C,H,Pr), [138°]. Formed from amidophenyl-propane, CS, and alcohol (F.). Plates.

PROPYL-PHENYL-UREA C₁₀H₁₁N₂O i.e. NH., CO.NHC₀H₁Pr. [143°]. Formed by the action of potassium cyanate on amido-phenyl-propane hydrochloride (Francksen, B. 17, 1225). Plates, sol. hot alcohol. insol. water.

Di-p-propyl-di-phenyl-urea CO(NHC,H,Pr), [205°]. Formed by heating amido-phenyl-propane with urea. Formed also by the action of COCL on amido-phenyl-propane in benzene, and by heating amido-phenyl-propane sulphate with a saturated solution of potassium cyanate. Needles, v. sol. ether and hot alcohol.

PROPYL PHOSPHATE PO(OPr), Formed, together with PrCl and PO(OH) (OPr) (which is sol. water) by the action of PCl, on n-propyl alcohol (Winssinger, Bl. [2] 48, 111). Oil. sl. sol. water, its insolubility being greatest at 75°. Cannot be distilled, even in vacuo.

ISOPROPYL PHOSPHINE PrPH, Formed, together with Pr.PH (118°) and Pr.P. by heating PrI with PH,I and ZnO for 6 hours at 100° (Hofmann, B. 6, 292). Liquid, with penetrating odour. Readily absorbs oxygen, taking fire on a hot day. - B'III : decomposed by water.

Tri-isopropyl-phosphine Pr.P. Oil. Forms red crystals with CS₂. -Pr₃PHI. Large crystals, v. sol. water. -Pr₄PI. Cubes or octahedra.

Di-chloro-isopropyl-phosphine PrPCl. 135°). Formed by heating HgPr, with PCl, (Michaelis, B. 13, 2175). Liquid.

Reference. - OAY-TRI-PROPYL-PHOSPHINE.

(240°). PROPYL PHOSPHITE P(OPr). S.G. 15 1.004. Formed from PCl, and NaOPr (Jachne, A. 256, 282). Liquid. •

ISOPROPYL ISOPHTHALIC ACID C, H, Pr(CO, H), [1:3:5]. [285°]. Formed by heating pyruvic acid with isobutyric aldehyde and Ba(OII)₂ (Doebner, B. 23, 2380; 24, 1748). Plates (from dilute alcohol, v. sl. sol. cold water).

—ВаА" 2 јаq. —СаА" 2 јаq. —Ад₂А" аq. PROPYL PHYCITE. According to Fauconnier (C. R. 107, 629), the substance described under this name by Carius (A. 134, 71) is glycerin.

PROPYL-PIPERIDINE v. PROPYL-PYRIDINE HEXARYDRIDE.

PROPYL-PROPANE v. HEXANE.

(a)-PROPYL-PYRIDINE C,II,1N i.s.

N CH. CH CH. Conyrine. (168°). Formed by distilling coniine hydrochloride with zincdust (Hofmann, B. 17, 825; Ladenburg, A. 247, Light oil, with blue fluorescence. picolinic acid [134°] on oxidation. Reduced by conc. HIAq at 290°. to conline. -B'2H2PtCl. [160°] and [172°]. Orange monoclinic tables. a:b:c = 1.0622:1:1.5356; $\beta = 87^{\circ}$ 13′.—B'MeI. Oil. -B'2Me2PtCle. Crystals, sl. sol. water.

Tetrahydride NII CII, CH, CH, CH₂-CH₂-CH₂-CH₂-CH₂-This is (γ)-coniceine (vol. ii. p. 248). Yields conline on reduction with tin and HCl (Lellmann a. Müller, B. 23, 680).

Hexahydride NH CH, CH, CH, CH, Inactive coniine. (167°). S.G. 9 .8626. Formed by reducing (a)-allyl-pyridine (derived from (a)methyl-pyridine and paraldehyde) in alcoholic solution with sodium (Ladenburg, B. 19, 2579; A. 217, 80). Oil, optically inactive. Can be separated by means of the acid tartrate into a dextro- modification (contine) and a lavo- modidextro- moduleativi (color) (L.); [213°] (L.) a. M.). V. sol. water.—B'₂H.PtCl₂.—B'₂H.Cdl₄. [118°]. (β) Propyl-pyridine N CH.CH. CH. Col-

lidine. (170°). Got by passing nicotine through a red hot tube (Cahours a. Etard, J. 1881, 928). Yields nicotinic acid on oxidation.

(a) - Isopropyl - pyridine NCH .CH >CH. (159°). S.G. 2 .9342. Formed, together with the (7)-isomeride, by heating pyridine with PrI and PrI at 290° (Ladenburg, B. 17, 772, 1121; 18, 1587; A. 247, 22). Liquid, with unpleasant 15, 1051; A. 221, 221. Inquia, with unpressant odour, sl. sol. water. Gives picolinic acid on oxidation with KMnO₄.—B'₂H₂PtCl₆. [170°]. Hexagonal rhombohedra, a:c=1:9489.—B'HAuCl₄. [91°].—B'C₆H₂N₄O₇. [116°]. Needles. Mercuric chloride double sglt: [90°].—

B'MeAuCl₄. [128°]. Tetra-hydride C₈H₁₅N. (164°). S.G. 2 896. Formed from the hexahydride, Br. and NaOHAq (Ladenburg, B. 20, 1646).—B'₂H₂PtCl₆. [189°]. Tables.

Hexahydride C.H., N i.e. NH CH₂ .CH₂ CH₂ CH₂ (159°). S.G. 2 ·8668. Formed by reduction in alcoholic solution by Na (Ladenburg, A. 247, 73). Liquid, more sol. cold than hot water. Converted by MeI into NMe CH₂ .Ch₂ CH₃ (167°). $(C_8H_{17}N)_2CS_2$ [105°]. — B'HCl. [210°]. metrie prisms; a:b:c = 814:1: 419. — B'HBr. [233°].—B'HI. [243°].—B'₂H₂PtCl₃. [193°]. Monoclinic prisms; a:b:c=·977:1:1·385; β = 89° 88'.—*Β',Η,CdI,. [133°].

v-Propyl-pyridine hexahydride

NPr CH, CH, CH, (149°-150°). Formed from piperidine and PrI (Ladenburg, B. 14, 1348). Liquid .- B'2H2SnCI : monoclinic crystals.

v-Isopropyl-pyridine hexahydride

NPr CH, CH, CH, -B', H, SnCle: monoclinic orystals (Hjortdahl, J. 1882, 1085).—B'2H2PtCla.

(γ) · Isopropyl · pyridine N CH:CH CPr. (178°). S.G. 2 .9439. Formed as above, being separated by means of the platinochloride, which is more soluble than that of the (a)-isomeride. Oil. Yields isonicotinic acid [305°] on oxidation.—B'2H2PtCl6. [205°]. Plates.

NH CH, CH, CH, CHPr. Hexahydride (171°). Formed by reducing (γ)-isopropyl-pyridine in alcoholic solution by Na. Funning liquid, v. sol. cold water.—B'₂H₂PtCl₂. [172°]. Golden prisms, sl. sol. water.

References. - OXY-PROPYL-PYRIDINE and OXY-

PROPYL-PIPERIDINE. PROPYL PYRIDYL KETONE v. PYRIDYL

PROPYL KETONE. PROPYL PYROGALLOL C,H,O, i.e. C,H,Pr(OH), [80°]. Got by heating its dimethyl ether with conc. HClAq at 130° (Hotmann, B. 8, 67; 11, 329). Prisms (from benz-ene), v. e. sol. water and alcohol. FeSO, colours

its aqueous solution blue (Pastrovitch, M. 4, 182).

its aqueous solution blue (Pastrovitch, M. 4, 182).

Methyl ether C₂H_Pr(OH)₂(OMe). (290°
cor.). S.G. 18 1-023. Occurs, together with the di-methyl ether, in beech-wood tar (Pastrovitch). Oil, with smoky smell. Gives an intense bluish-green colour with FeCl₂ in alcohol.—C₂H_Pr(OK)₂(OMe). Pearly crystals (from dilute alcohol).—C₂H_Pr(OAc)₂(OMe). [83°]. Needles (from alcohol).—C₃Br₂Pr(OAc)₂(OMe). [79°]. Golden needles.

Di-methyl ether C.H.Pr(OH)(OMs). Picamar. (c. 286° cor.). Occurs in beech-wood tar (Reichenbach, A. 8, 224; Niederist, M. 4, 487). Oil, with bitter, burning taste. Reduces salts of Au and Ag. Yields the di-methyl ether of di-oxy-quinone on oxidation .- C11H18O3K. Pearly leaflets (from spirit).—C₁₁H₁₈AcO₄. [87°]. Monoclinic prisms; a:b:c=39:1: 547; B Petry leaders (100 prisms; a:b:c='39:1:'547; B Monoclinic prisms; a:b:c='99:...'G₁H₁₃Br₂AcO, [101°]. Trimetric prisms; a:b:c='99:1:1:'93.-C₁H₁BzO₂. [91°]. Trimetrio

Tri-methyl ether C.H.Pr(OMe). (164°). Formed from propyl-pyrogaliol and MeI (Will, B. 21, 2020).

n-PROPYL-PYRROLE C,H, N i.s.

NPr CH:CH. (147°). Formed from potassium

pyrrole and PrI (Zanetti, B. 22, 2518). Liquid. Isopropyl-pyrrole C,H,PrN. (174°). Formed by boiling pyrrole with acetone and ZnCl₂ (Dennstedt a. Zimmermann, B. 20, 851; 21, 1480). Liquid. Dry HCl passed into its ethereal solution forms (C,H₁₁N)₂HCl, a crystalline salt yielding a liquid base (c. 287°) and a picrate (C,H₁,N₂C,H₁N₂O, [146°]. Ac₂O forms C,H₁!r:NAc (222°-232°) and C,H₂AcPr:NH [64°] (251°).

ISOPROPYL-PYRRYL STYRYL KETONE NHC, H.Pr.CO.CH:CHPh. [143°]. Formed by boiling NHC, H.Pr.CO.CH, with benzoic aldehyde and dilute KOHAq (Dennstedt a. Zimmermann, B. 20, 853). Yellow crystals.

(B. 3)-ISOPROPYL-QUINOLINE C, H, N i.e. CH:CH.C.CH:CH Cumoquinoline. CPr:CH.C.N = CH by heating (Py. 3)-chloro-isopropyl-quinoline with a solution of HI in HOAc (Widman, B. 19, with a solution of ri ii in lock (Widman, B. 13, 267). Oil, easily volatile in steam.—Salts: B'2H_PtCl_2aq. [220°].—Piorate: [206°].—Chromate: [c. 92°]. Large red prisms.

Methylo-locked B'Mel. [c. 200°].

(Py. 2).Isopropyl-quinoline C_cH₄CH₇CPr. [c. 10°]. (275°-280°) at 715 mm. Formed by distilling its (Py. 3)-carboxylic acid (Spady, B. 18, 3383). Liquid, v. sol. alcohol and ether.—B'₂H₂PtCl₈.—B'₂H₂Cr₂O₄.— B'C,H,N,O,: long slender needles.

(Py. 3)-Isopropyl-quinoline C_8H_4 N = CPr(255°). Formed by heating its (Py. 1)-carboxylic acid with soda-lime (Doebner, B. 20, 279; A. 242, 279). Oil, smelling like quinoline. B' H.PtCl, 2aq: yellow needles.—B'C.H.N.O.,. [150°]. Yellow plates (from alcohol).

Reference.-CHLORO- and OXY- ISOPROPYL-

QUINOLINE.

(Py. 2)-ISOPROPYL-QUINOLINE (Py. 8)-CARBOXYLIC ACID C.H. CH:CPr [189°]. Formed by oxidation of (Py. 2,3)-isopropyl-isobutyl-quinoline with CrO₂ and dilute H₂SO₄ (Spady, B. 18, 3379). Plates (from dilute alcohol).—AgHA',HNO₂.—(HA'),H,PtCl₂: prisms.

(Py. 3)-Isopropyl-quinoline (Py. 1)-earboxylic acid C₂H₂C(CO₂H):CH₂C(P₂C). [146°]. Formed, together with C,H,N,O [222°], by adding aniline to an alcoholic solution of isobutyric aldehyde and pyruvic acid (Doebner, A. 242, 276; B. 20, 279). Prisms (containing 1;aq).

lemon-yellow needles .-- AgA'.

PROPYL SILICATE Si(OPr). (226°). S.G. 12 .915 (Cahours, C. R. 76, 1383). On heating On heating with SiCl, at 160° it yields (PrO), SiCl (209°) and (PrO), SiCl, (187°).
DI-PROPYL-DI-STYRYL KETONE

(C,H,C,H,CH:CH),CO. [106°]. Formed from cuminic aldehyde, acetone, alcohol, and NaOHAq (Claisen a. Ponder, A. 223, 148). Prisms.

ISOPROPYL-STYRYL-PHENOL. ether. C.H.Pr.CHICH.C.H.OMe. [152°]. Gob by heating C.H.Pr.C(CO₂H); CH.C._eH₄OMe (Magnanini, G. 15, 513). Pearly scales (from alcohol). PROPYL-SUCCINIC ACID C.H.₁₂O₄ i.e. CO₂H.CH₂.CHPr.CO₂H. Oxy.hexic acid. [92°].

Formed by heating pentane tri-carboxylic acid (Waltz, B. 15, 608; A. 214, 59). Got also by reducing oxy-hexic acid with zinc and H.SO, (Gorboff, J. R. 1887, 605; Walden, B. 24, 2036).
Iso-propyl-succinic acid v. Pimelic acid.

Di-isopropyl-succinic acid C_{1e}H_{1e}O₄ i.e. CO₂H.CHPr.CHPr.CO₂H. [168°]. The ether is formed from a-bromo-isovaleric ether and finelydivided silver (Hell a. Mayer, B. 22, 48). Dendritic crystals (from water).—BaA" 5aq. S. 7-7 at 17°.—CuA" aq. S. °099 at 24°.—SrA" 3aq.—CaA" 4aq.—MgA"7aq.—CoA" 7aq.—NiA" 5aq.—CdA" 4aq.—MnA" 7aq. S. 4.71 at 21°.—ZnA".

—PbA".—Ag,A". S. °062 at 20°.

Tamparid. C. H. O. (2000).

Reference. - OXY-PROPYL-SUCCINIC ACID. TETRA-PROPYL-SUCCINIMIDINE C, H, N,

i.e. CH:C(NPr₂) N. Got from succin-imido-CH, C(NPr₂) N. Horizond alcohol at ethyl ether hydrochloride, NHPr., and alcohol at 50° (Pinner, B. 23, 2930).—B'2HNO, [53°].— B'₄H.PtCl. [174°]. Needles, sl. sol. hot water. PROPYL SULPHATES.

Propyl sulphuric acid Pro.So..OH. Formed arom propys atconol and H₂SO₄ (Chancel, C. R. 87, 410). — KA': needles, v. sol. water. — BaA'₂ 8aq (Schmidt, Z. 1870, 576).
Di-propyl sulphate Pr₂SO₄. Formed from propyl alcohol and CISO₂OH (Mazurowska, J. pr. [2] 18, 162). Oil. from propyl alcohol and H₂SO₄ (Chancel, C. R.

DI-n-PROPYL SULPHIDE Pr.S. (Winssinger, Bl. [2] 48, 109). S.G. 17 ·814 (C.). Occurs in raw petroleum (Mabery a. Smith, \hat{B} . 22, 3303). Formed by heating K2S with PrCl or Pri in alcohol (Cahours, C. B. 76, 133). Fetid oil. Brome-acetic acid forms the acid Pr.SBr.CH.CO.H. which yields Pb.A'Br, and Pb2A'Br3 (Letts, Tr. E. 28, 586).

Compounds with platinum salts (Blomstrand, J. pr. [2] 38, 354, 408).— (Pr.S).PtCl. Occurs in three varieties: (a) [46°] S. (alcohol) 15°6 at 15°, (a) [66°], and (γ) [63°]. Alcoholic KOH (1 mol.) acting on the (a)-com-Alcoholic ROH (1 mol.) acting on the (a)-compound forms crystalline (Pr.S),Ptcl(OH).—

(Pr.S)(Et,S)PtCl.; syrup.—(Pr.S),Pt.Cl., [185°].—(Pr.S),PtBr., [185°].—(Pr.S),PtBr., [185°].—(Pr.S),PtBr., [185°].—(Pr.S),PtBr., [185°].—(Pr.S),PtBr., [185°].—(Pr.S),PtBr., [185°].—(Pr.S),PtBr., [185°].—(Pr.S),PtBr., [185°].—(Pr.S),PtBr., [181°].—(Pr.S),PtJ., [181°].—(Pr.S),PtJ.

HAHG. — (HA), H.PtOl, aq. — (HA'), HAuCl.; | [210°] and [195°].—(Pr,S), Pt(NO,), Occurs in [210°] and [195°].—(Pr.B),Pt(NO₁).—Occurs in two varieties, an oil and a crystalline body [70°] which yields (Pr.S),Pt(NO₂)(OH) [145°].— (Pr.S),PtCrO₂. Bod prisms (from chloroform). (Pr.S),PtC₂O₄: crystalline pp.—(Pr.S),Pt(SON₂: yellow pp.—(Pr.S),PtOl,HgCl₂. [82°]. Trimetrie crystals, a:b:c=:554:1::591.

Propylo-iodide SPr.I. Yields the compound (SPr.Cl).PtCl, (Cahours).

Isopropyl sulphide Pr.S. (121° i.V.). Formed by distilling PrI with alcoholic K.S (Henry, B. 2, 495; Beckmann, J. pr. [2] 17, 459). Oxidised by KMnO, to Pr.SO, [36°]. Yields Pr.SHgOL.

by Kand, to Fr₂SO₂ [30°]. Items Fr₂SI₃GU₂ Compounds with salts of platinum (Blomstrand):—(Pr₂S)₂PtCl₂. [163°].— (Pr₂S)₂PtBr₂. [174°].—(Pr₂S)₂Ptl₃. [176°].—(Pr₂S)₂Pt(SON)₂. [102°].—(Pr₂S)₂Pt(NO₃)₂. Prisms, decomposing at 210°.—(Pr₂S)₂PtI₄, [189°]. Di-propyl disulphide Pr.S. (193°). (Spring a. Legros, B. 15, 1940)

Di-isopropyl disulphide Pr.S. (175°). A product of the action of Na and MeI on isopropyl mercaptan in ether (Obermeyer, B. 20, 2928).

PROPYL SULPHOCYANIDE PISCN. (163°). Liquid (Schmidt, Z. 1870, 576).

Isopropyl sulphocyanide PrSCN. (Henry, B. 2, 496); (153°) (Grlich, A. 178, 90). S.G. 2º 963. Formed from PrI and potassium sulphocyanide. Liquid, decomposed by boiling water. H₂S yields NH₂.CS₂Pr [97°].

DI-n-PROPYL SULPHONE Pr₂SO₂.

Formed by oxidising Pr.SO (Winssinger, Bl. [2] 48, 111). Scales, sol. water, alcohol, and ether Volatile with steam.

Di-isopropyl sulphone Pr., SO., [36°]. Got by oxidising Pr., S with KMnO. (Beckmann, J. pr., [2] 17, 459). V. sol. water and HClAq. Not

affected by reducing agents.
DI-PROPYL SULPHONE DICARBOXYLIC ACID SO. (CHEt.CO.H). Sulpho-dibutyric acid. [152°]. Formed from SO. (CH. CO.Et), Et1. Dimetric and NaOEt (Lovén, B. 17, 2817). octahedra.

Di-isopropyl sulphone dicarboxylic acid SO₂(CM₂,CO₂H)₂, [188°]. Formed from SO₂(CH₂,CO₂Ht)₄ (1 mol.), MeI (4 mols.) and NaOEt (4 mols.) (Lovén, B. 17, 2824).

DI.PROPYL SULPHOXIDE Pr.SO. [15°].

Got by oxidising Pr.S with dilute HNO. (S.G. 1.2) (Winssinger, B. 16, 329; Bl. [2] 48, 110). Needles, sol. water, alcohol, and ether. Decomposed by heat. Readily reduced to Pr.S. Calcium nitrate forms (Pr2SO),5Ca(NO2)2, a fibrous mass [80°].

B-ISOPROPYLTHIENYL ETHYL KETONE C,H,PrS.CO.C,H,. (251°). Formed from (\$). isopropyl-thiophene, propionyl chloride, and AlCl, (Thiele, A. 267, 136). Oil, volatile with steam. Appears to yield isopropyl-thienyl-glyoxylic acid on oxidation with alkaline KMnO

PROPYL THIENYL PLYOXYLIC ACID C,H2PrS.CO.CO,H. Formed by oxidising propyl thienyl methyl ketone with alkaline KMnO. (Ruffi, B. 20, 1745). Solid.—AgA'.
PROPYL-THIENYL METHYL KETOME

C.H.Prs.CO.CH., (255°). Formed by the action of AcCl and AlCl, on a solution of (a)-propylthiophene in ligroin (Ruffi, B. 20, 1744). Liquid. Yields an oxim [55°] and a phenyi-

Isopropylthienyl methyl ketone

C.H.Prs.CO.CH. (237°). Formed from iso-propyl-thiophene, AcCl, and AlCl, (Thiele, A. 267, 187). Oil. Yields a crystalline oxim and phenyl-hydrazide.

PROPYL-DI-THIO-BIURET C,H,1N,S, i.e. NH2.CS.NH.CS.NHPr. [121°]. Formed from sodium cyanamide and propyl-thiocarbimide (Hecht, B. 25, 754). Crystalline mass, v. sl. sol.

cold water.

PROPYL-THIOCARBIMIDE PrN:CS. (153°). S.G. % 9909; 89 8924. Formed from propylamine and CS₂ followed by HgCl₂ (Hecht, B. 23, 281. 1662). Pungent liquid, al. sol. water, miscible with alcohol and ether. Sodium cyanamide and alcoholic MeI form NHPr.CS.NCyMe [115°]. In the same manner may be prepared MHPr.CS.NCyEt [56°], MHPr.CS.NCyC₂H₅ [50°], NHPr.CS.NCyC₂F₆ [50°] erystallising in needles, and NHPr.CS.NCy.CH₂Ph [113°].

Isopropyl-thiocarbimide PrN:CS.

Pungent liquid (Jahn, M. 3, 168).

PROPYL DI-THIO-CARBONATE Pro.CS.SH. Unstable oil.—Pro.CS.SK. Formed from CS. and KOH dissolved in propyl alcohol (Scala, G. 17, 78). Silky needles. Its aqueous solution gives an orange pp. with CuSO₄. Iodine forms oily (Pro.CS)₄S₂ decomposing at 180°. – Pro.CS.SMe. (202°). Oil.—Pro.CS.SEt. (216°).

(a)-PROPYL-THIOPHENE C.H.PrS. (158° cor.). S.G. 16 974. Formed from iodo-thio-phene, PrBr, and Na (Meyer a. Kreis, B. 17, 1561). Oil. Yields (a)-thiophenic acid on oxidation.

Isopropyl-thiophene C_4H_3PrS . (154° cor.). S.G. 19 9695. Formed from PrBr, thiophene, and AlCl, (Schleicher, B. 19, 672). Oil with powerful odour. With HOAc, phenanthaquinone, and H2SO4 it gives a deep violet colour.

\$-Isopropyl-thiophene CH:CH S.

Formed by distilling sodium isopropyl-succinate with P.S. (Thiele, A. 267, 133). Oil, smelling like benzene, insol. water, miscible with alcohol. ether, and benzene. Forms C3H, C4H2S.HgCl [137°] crystallising from alcohol in white needles, and C,H,.C,HS(HgCl)2 as white grains, insol. alcohol (Volhard, A. 267, 183).

References. — Bromo-, Iodo-, and Nitro-

PROPYL-THIOPHENE.

PROPYL-THIOPHENE CARBOXYLIC ACID C.H.PrS.CO.H. [57°]. Formed from iodopropyl-thiophene, ClCO,Et, and sodium-amalgam; the product being saponified by alcoholic potash (Ruffi, B. 20, 1743). Needles (from warm water), or plates (from dilute alcohol).
PROPYL THIOSULPHATE.

Prs.SO, Na 5aq is made from Na, S,O, and PrI

(Spring a. Legros, B. 15, 1938). PROPYL-THIO-UREA NHPr.CS.NH₂. [110°]. Formed from propyl-thiocarbimide and NH Aq in the cold (Hecht, B. 23, 283). Four-sided plates, sol. alcohol.

Isopropyl-thio-urea NHPr.CS.NH2. [157°].

Plates (Jahn, M. 3, 168).

Di - propyl - thio - urea CS(NHPr)2. Formed in the preparation of propyl thiocarb-

imide. Pearly plates (from water).

Di-isopropyl-thio-urea CS(NHPr)2. [1619]. Reedles (from hot water) (Juhn).

PROPYL-TOLUENE v. CYMENE.

PROPYL-TOLUIC ACID v. CYMENE CARBOXYLLC

n-PROPYL-p-TOLUIDINE C10H15N C₀H₁Me.NHPr. (232°). S.G. $\frac{32}{2}$ 9296. $\mu_{\rm D}$ = 1.5367. S.V. 197.53. R_{∞} = 82.5. Formed by heating *p*-toluidine (1 mol.) with PrI (1 mol.) for two days at 160°; the yield being 90 p.c. of the theoretical amount (Hori a. Morley, C. J. 59, 36). Purified by means of the nitrosamine. Oil. Salts.-B'HCl. [151°]. Needles (from boiling benzene), v. sol. water and alcohol .-- B'H2C2O4. [173°]. S. (alcohol) 1.4 at 21°. Ppd. on mixing alcoholic solutions of the base (1 mol.) and oxalic acid (1 mol.). Sl. sol. cold water and alcohol.—B'_HI_C_O_. [117°]. Occurs in the filtrate from the preceding salt, and formed also when a large excess of base is added to a cold alcoholic solution of the acid oxalate. Crystals, m. sol. cold water and alcohol. Decomposed by boiling water, B'H,C,O, being ppd.—B',H,FeCy.

Nitrosamine C,H,Me.NPr.NO. Oil, not

solid at -20°. Decomposes below 100° Isopropyl - p - toluidine C₀H₁Me.NPr.NO. (220° uncor.). S.G. ²³ 9129. $\mu_{\rm b}=1.5322$. S.V. 199.57. $\rm R_{\odot}$ 81.4. Formed by heating PrI with p-toluidine for two days at 130° (Hori a. Morley, C. J. 59, 34). Got also by heating diazotoluene toluide C.H., N., NHC, H., with alcoholic NaOEt and PrI for 5 hours on the water-bath,

distilling off the alcohol, pouring into water, and

decomposing the pp. with HCl. Oil.
Salts. - B'HCl. [171°]. Wax-like crystals. (from alcohol) or needles (from benzene), v. sol. water.—B₂H.G.O₄, [130°]. S. (alcohol) 5.76 at 22°. Crystals (from dilute alcohol). The acid

oxalate is not easily crystallisable.—B.H.FeCy,
Nitrosamine C.H.Mo.NPr.NO. [59°]. S.
(alcohol) 65 at 22° Yellowish crystals (from

alcohol), not volatile with steam.

Reference .- OXY-PROPYL-TOLUIDINE. PROPYL UREA. NH. CO.NHPr. Formed from propyl cyanate and NH3, and from potassium cyanate and propylamine sulphate (Chancel, Bl. [3] 9, 101). Long needles, sol. water and alcohol. Its oxalate and nitrate are v. sol. water. Decomposed by HClAq in a sealed tube at 160° into NH, NH, Pr, and CO, Butyryl derivative NHPr.CO.NH(CO.C, H.). [99°]. Formed by the action of cold KOHAq on a mixture of butyramide (2 mols.) and bromine (1 mol.) (Hofmann, B. 15, 757). Colourless plates, sl. sol. water.

Isopropyl-urea. Isobutyryl derivative NHPr.CO.NH.COPr. [86°]. Formed in like manner from the amide of isobutyric acid.

Tables, sol. alcohol and ether.

NH, CO.NPr, u-Di-propyl-urea Formed from dipropylamine and KCyO. Needles (from alcohol). Its oxalate crystallises in needles, sl. sol. water.

s-Di-propyl-urea CO(NHPr)2. [105°]. (255°). Got by boiling the corresponding thio-urea with HgO and water (Hecht, B. 23, 285), or from PrCyO and aqueous NH_Pr. White plates (from water). Sl. sol. cold water, v. sol. alcohol and ether. Its salts are decomposed by water.

Di-propyl-urea C,H₁₈N₁O i.e. NH₂-CO.NPr₂

[76°]. Formed from propylamine sulphate and potassium cyanate (Von der Zande, R. T. C. 8, 228). Needles. An ethereal solution of aldehyde forms CH, CH(NH.CO.NPr.); [118°]. Chloral

hydrate gives CCl₂.CH(OH).NH.CO.NPr₂ [128°] called peptones, which after absorption undergo and in aqueous solution (C₂H₁₂N₂O)C.HCl₂O aq reconversion into proteids, [51°]. CEnanthol in ethereal solution gives Although much work has been done in at C,H₁₄(NH.CO.NPr₂), [113°].—B', H₂C₂O₄. [103°]. -B'C.H.N.O,. [135°].-B'2HNO.

s-Di-isopropyl-urea CO(NHI'r)2. Formed as a by-product in the production of isopropyl Na_aCO₄ (Hofmann, B. 15, 756). Needles, sol.

u-Di-isopropyl-urea NH_CO.NPr.. Formed by evaporating a solution of isopropylamine sulphate with potassium cyanate (Von der Zande, R. T. C. 8, 231). Crystals (from ether). An ethereal solution of aldebyde forms CH_xCH(NH.CO.NPr_x)_x[147°]. Chloral in ethereal solution gives CCl_x.CH(OH).NH.CO.NPr_x [121°]. $-B'_{2}H_{2}C_{0}$, [111°]. Nécdles. $-B'C_{e}H_{3}N_{3}O_{7}$. [134°]. Necdles. $-B'HNO_{1}$. [79°].

Reference.—DI-BROMO-PROPYL-UREA.

PROTAGON v. LECTTHIN.

PROTAMINE C₉H₂₁N₃O₃ or C₁₈H₃₁N₉O₄.

Occurs in the seminal substance of the salmon in November (Micscher, B. 7, 376; Piccard, B. 7, 1714). Gummy mass, insol. alcohol and ether, sol. water with alkaline reaction. Its salts give with K_sFeCy_s a milky pp. composed of minute drops. Salts.—(C₀H₁N₁O₀) H₂PtCl_s (M.); C_{1s}H₃₁N₁O₁H₂PtCl_s (P.). Yellow powder.

PROTEIDS. (Πρωτείου, 'pre-eminence.') This

name is given to a large group of organic compounds which are also known as 'albuminous.' The word 'proteid' itself has been retained simply as a convenient general term, and not as implying any adherence to the theory, first advanced by Mulder, that they all contain a complex molecule to which he gave the name of 'protein.' The word albumin is now limited to a certain class of proteids, and the word albuminoid. though it is still largely used synonymously with proteid, is restricted by physiological chemists to a class of nitrogenous substances (which includes such substances as gelatin and mucin) which are not proteids, but still in certain reactions resemble those substances closely.

Proteids are never absent from the protoplasm of active living cells, whether animal or vegetable, and they are indissolubly connected with every manifestation of organic activity. A definition of proteids is not possible in the logical sense. Gamgee (Physiol. Chem. p. 4) gives in the following sentences a terse description of these substances, which must take the place of a definition: 'Proteids are highly complex, and for the most part non-crystallisable compounds of carbon, hydrogen, nitrogen, oxygen, and sulphur, occurring in a solid viscous condition or in solution in nearly all the solids and liquids of the organism. The different members of the group present differences in physical, and to a certain extent in chemical, properties; they all possess, however, certain common chemical reactions, and are united by a close genetic relationship.

In vegetables the proteids are constructed out of the simpler chemical compounds which serve as their food. In animals such a synthesis never occurs, but the proteids are derived directly or indirectly from vegetables. By the action of certain digestive juices all proteids are capable of being converted into closely allied substances

tempting to unravel the constitution of the proteids, there is at present but little positive to be said on this point. All we can do is to give the result of the experiments that have been performed which show the classes of products yielded by the proteids, and to enumerate the various theories held by different observers concerning their constitution.

The various proteids differ somewhat in elementary composition within the limits of the following numbers (Hoppe-Seyler, Handbuch d. Phys. und Path.-Chem. Analyse, 4to Aufl. p. 223):

The various decompositions that proteids undergo may be conveniently stated under the following heads:-

a. Decomposition in the body. In the alimentary canal the proteids are converted into proteoses (albumoses) and peptones: this change is probably due to hydration. Under the influence of the pancreatic ferment, a certain class of peptones called hemi-peptones are further acted upon, resulting in the formation of leucine, tyrosine, aspartic acid, ammonia, and proteinchromogen (a substance coloured purple by bromine). Putrefactive processes due to bacteria in the small intestine also occur; these result in the formation of indole, skatole, phenol, and oxyacids. Ethereal hydrogen sulphates can be detected in the urine as a result of these putrefactive changes (Baumann, H. 10, 123); when putrefaction is hindered by the administration of large doses of iodoform in dogs, these products do not appear in the urine (V. Morax, H. 10, 318). One of the sources of hippuric acid in the urine of flesh-feeders is the phenyl-propionic acid that results from the putrefaction of proteids in the alimentary tract (Salkowski, B. 12, 648; Tappenier, Z. B. 22, 236).

After the proteids have been absorbed from the alimentary canal, they become assimilated by the tissues, and there undergo combustion or metabolism, the chief ultimate products being water, carbonic acid, and urea. It is probable that glycocine, leucine, creatine, and ammonium carbonate are intermediate products in this change. Urea had not been obtained from proteids by experiments performed outside the body until quite recently, when Drechsel (B. 23, 3096) has succeeded in obtaining a crystalline base lysatin by acting on casein with zine and hydrochloric acid. Lysatin yields urea when boiled with baryta water. It has also been demonstrated, by experiments on animals, that proteid food gives rise to glycogen in the liver, and to fat in the subcutaneous and other tissues. That proteids can be converted into fats is also shown by the occurrence of adipocere in the muscular tissues after death.

b. Action of heat. By dry distillation the proteids yield an oily liquid called Dippel's oil, which contains ammoniacal salts of the fatty acids, amines, and aromatic compounds.

c. Action of putrefaction. The chief products

are ammonia, ammonium sulphide, carbonic acid, volatile fatty acids, lactic acid, amines, Nucine, tyrosine, and other complex aromatic

compounds.

d. Action of acids and alkalis. Prolonged boiling with strong sulphuric or hydrochloric acid, or fusion with caustic alkalis, gives rise to a large number of products, of which the following are the most important; leucine, tyrosine, aspartic acid, and glutamic acid. Prolonged heating with dilute acids gives rise to hydrolytic decomposition (Hermann) and the dormation of albumoses and peptones (Neumeister, Z. B. 23,

The effect of heating proteids with caustic baryta was investigated by Nasse, and subsequently by Schützenberger (Bl. Feb. 15, March 5 and 15, 1875). Ammonia was evolved, and carbonic acid remained in combination with barium; these two products occurred in the same ratio as would result from urea similarly treated. In addition oxalic acid, acetic acid, tyrosine, amidoacids of the fatty acid series (especially leucine, butylamine, and amido-butyric acid), acids allied to glutamic and aspartic acids, and lastly a dextrin-like substance, were found in the residue. Schützenberger (A. Ch. [5] 16, 289) explains the mechanism of the reaction as follows: the proteid molecule, losing ammonia and carbon as carbonic oxalic, and acetic acids, and assimilating water, is converted into a mixture of glucoproteins $C_nH_mN_2O_4$, containing as its principal term $C_0H_{1n}N_2O_4$; by the prolonged action of baryta at a high temperature these split up partly into leucines or amido- acids of the acetic series $C_nH_{m+1}NO_2$ and leuceines or amido-acids of the acrylic series $C_nH_{m-1}NO_2$, and partly into double compounds formed by the union of glucoproteins and leuceines with the leucines. For Schützenberger's recent attempts to synthesise proteids see C. R. 112, 198.

e. Action of hydrochloric acid and stannous chloride. Ammonia, aspartic acid, glutamic acid, leucine, and tyrosine are the chief products (Hlasiwetz a. Habermann, Anz. Wien. Acad. 1872, 1873; A. 159, 304; 169, 150; J. pr. 7, 897).

f. Action of oxidising agents. By means of manganese dioxide and sulphuric acid, or potassium chromate and sulphuric acid, many fatty and aromatic compounds are formed. Nitric acid produces first a yellow insoluble substance, xantho-proteic acid, which dissolves on further action, and yields ultimately para-oxybenzoic and oxybenzoic acids.

Mulder (J. pr. 16, 129; 17, 312; A. 31, 129) obtained by the action of potash on proteids a substance which is now called alkali-albuminate. but which was regarded by Mulder to be the base of all proteids; he gave it the name 'protein.'
Various definite compounds of protein were described, such as oxyprotein, trioxyprotein, sulphoproteic acid, &c. Liebig (A. 57, 132) was the first to disprove these assertions, and the only remnant of this theory now is the term 'proteid. For recent work on this subject and the related one of sulphur in proteids see Danilewski (H. 7, 440), and Krüger (Pf. 43, 244).

Gerhardt was of opinion that all the proteids are identical in constitution and molecular arrangement, but differ from one another in the

nature of the mineral substance with which they are associated. He designated the common organic element by the name 'albumin,' and it may be mentioned that in the elaboration of his theory he regarded egg albumin as the neutral albumate of sodium, and fibrin as a compound of albumin with earthy phosphates. Proteids, however, have been separated from all but traces of mineral matter, and still exhibit their peculiar characteristics; careful elementary analysis also has shown that there is a difference of the percentage amounts of carbon, nitrogen, sulphur, &c., in various proteids. Nevertheless, it is still a fact that some of the distinguishing features of certain proteids are due to the adhering salt; for instance, the coagulation of caseinogen by rennet occurs only in the presence of calcium

salts (Hammarsten).

Gautier (Chimie appliquée à la Physiologie, i. 251) states that the proteids behave as amides of the higher homologues of lactic and tartaric acids, and residues of aromatic acids; hence when proteids are oxidised there is a simultaneous production of fatty acids, of aromatic compounds, and doubtless of bodies analogous to urea; the products furnished by different proteids are not in the same proportions. It must, therefore, follow that the different radicles they contain differ not only in arrangement but in relative proportion, and sometimes even in their nature. It was Nasse who first observed (Pf. 6, 589) that the nitrogen in proteids appears to exist in two conditions, a certain fraction of it being more unstable and apparently more feebly combined than the rest. This view was fully confirmed by Schützenberger in the experiments already alluded to. The latter observer regards the proteids as complex ureides, i.e. combinations in various proportions of urea with amido-acids, some of which belong to the leucine series, others to the aspartic series. Representing albumin by the empirical formula $C_{r2}H_{112}N_{18}O_{22}S$ (Lieberkühn), it yields, when decomposed by caustic baryta, urea, acetic acid, a sulphur-containing body, and a substance with the formula $C_{88}H_{132}N_{14}O_{24}$, which may on further hydration be split up into the substances already mentioned (glucoproteins, leucines, leuceines, &c.).

Pflüger's view relative to the constitution of the proteids (Pf. 10, 251) may be thus summarised. One of the most striking features of the proteids is the difference that exists between nonliving proteid matter, such as white of egg, and that which forms part of living protoplasm. former may remain for years without undergoing decomposition, and is indifferent to neutral oxygen; while the latter is continually decomposing, undergoing intramolecular changes, and lives by breathing oxygen. The assimilation of proteid food is looked upon by Pflüger as an ether-like combination of a molecule of living proteid with one of the non-living proteid, water being climinated. This union of isomeric molecules, which forms a heavy mass but still remains a simple molecule, may be conceived to go on indefinitely. In this process it seems probable that the nitrogen of the food proteid, which exists there in combination as amides, passes into combination with carbon, so that in living proteid it is combined in the form of cyanogen. This view is strengthened by the fact that substances like uric acid, creatine, and guanine, are products of proteid metabolism, while such compounds are never obtained from non-living proteid material. O. Loew (Die chemische Kraftquelle im Lebenden Protoplasme, Munich, 1882, B. A. 1885, p. 1075) has also found that a striking difference between living and non-living proteids is the fact that the former reduce silver nitrate, probably owing to some radicle of the nature of addehyde, whereas the latter do not behave in this way. He suggests that albumin is a condensation product of aspartic aldehyde. The simplest formula for Schützenberger's leucene O,H,NO, is also that of aspartic aldehyde.

Latham (Brit. Med. Journ. [1] 1886, 629) regards albumin as a compound of cyan-alcohols united to a benzene nucleus. The cyan-alcohols resemble proteids in readily undergoing condensation and intramolecular changes; and, morcover, the various products of the disintegration of proteids can also be obtained as the decomposition products of these cyan-alcohols. See also Drechsel's art. in Ladenburg's Handw. d. Chem. 3, 541; Beilstein's Handw. 3, 1258.

GENERAL PROPERTIES OF PROTEIDS.

- 1. Indiffusibility. Solutions of proteids are non-diffusible. They belong to Graham's class of colloid substances. Peptones, and to a less extent cibumoses, are, however, diffusible. This property of indiffusibility enables us to separate proteids from saline admixtures, and also to separate various proteids from one another: e.g. if a mixture of albumin and globulin in a saline solution be dialysed, the salts pass out, the albumin remains within the dialyser in solution, while the globulin, which is insoluble in water, is precipitated.
- 2. Action on polarised light. Proteids all rotate the plane of polarised light to the left. The following table gives the specific rotatory power for the yellow line D of some of the chief proteids:

of various proteids is usually characteristic, but it can be varied somewhat by additions of small quantities of acid or alkali; the former lowers, the latter heightens, the coagulation temperature. Alkali albumin in the latter case is not coagulable by heat, and forms so readily that it is advisable to have the solution either perfectly neutral or faintly acid before performing the experiment. Rendering the liquid faintly soid with weak (2 p.c.) acetic acid also renders the flocculi of precipitate larger and easier to filter off. The alkalinity of a liquid is always increased, or its acidity diminished, after the separation of a heat congulum. Various neutral salts in excess also cause the coagulation temperature to vary; sodium chloride lowers the temperature. while magnesium sulphate has little or no effect. A solution of proteid enters into an opalescent condition a few degrees below that at which the separation of flocculi begins. In the dry state proteids are rendered insoluble, like coagulated proteid, at a temperature of 110°C. On the influence of salts on coagulation temperatures, see Limbourg (II. 13, 450). Haycraft criticises the method of fractional heat coagulation (Pr. Roy. Soc. Edin. 1888-9, 361). It is defended by numerous observers (for references see Halli-burton, J. Physiol. 13, 806; Hewlett, ibid. 798). The following table gives the heat coagulation temperatures of some of the most important pro

oteids:				
Proteid			Te	mperaturs of heat congulation
Egg albumin				72 8°C.
Serum albumin	α			72 -8°
Vitellin .	•	•	•	75°
Serum globulin		•	•	75°
Fibrinogen	٠	•	•	56°
Myosin .	•	•	•	560
Crystallin .	•	•	•	93° 65°
Hæmocyanin	•	•	•	09-

4. General tests for proteids. Solutions of the proteids are precipitated by strong mineral

•	1	
Proteid	Observer	Value of [a]

Syntonin (from egg albumin) .	Наав	- 63·12°
Syntonin (from myosin)	Hoppe-Seyler	-72°
Casein (in weak MgSO, solution)	Hoppe-Seyler	80°
Serum-globulin	Haas	- 59·7 5°
Various albumoses	Kühne a. Chittenden (Z. B. 20, 51)	-70° to 80°

According to Haas, these numbers are unaltered by the salts adherent to the proteids.

3. Heat coagulation. Most of the native proteids are coagulated by heating their solutions, but more especially the globulins and albumins. By this means the character of the original proteid is lost, and all are converted into an exceedingly insoluble substance, called 'coagulated proteid.' When several proteids are mixed in a solution, if their temperature of coagulation differs, it is possible to separate them by a process of 'fractional heat accordation.' The heat coagulation temperature

acids, acetic acid and potassium ferrocyanids, by acetic or oxalic acid together with a large addition of concentrated solutions of neutral salts, by basic lead acetate, by mercuric chlorids, by copper sulphate, by tannic acid, by saturation with powdered potassium carbonate, ammonium sulphate or sodio-magnesium sulphate, and by alcohol.

'coagulated proteid.' When several proteids are mixed in a solution, if their temperature of coagulation differs, it is possible to separate them by a process of 'fractional heat engulation.' The heat coagulation temperature phuretted hydrogen, and the proteid again ob-

tained unaltered. Neutral salts like ammonium sulphate, or sodio-magnesium sulphate, completely precipitate all proteids but peptones, and in an uncoagulated condition—i.e. they can be re-dissolved in water or weak saline solutions, and exhibit their characteristic properties. Alcohol precipitates proteids, and after long contact with the precipitate converts them into 'coagulated proteid.' The following reactions are those most frequently employed in the de-

tection of proteids in solution:

(a) The xanthoproteic reaction. Nitrie acid is added; this usually produces a precipitate, but in the case of peptones, or if the quantity of proteid is very small, it does not. The mixture is then boiled, when the liquid and the precipitate turn yellow (xanthoproteic acid); if it is boiled sufficiently long with excess of acid the precipitate dissolves. Addition of ammonia causes the yellow colour to become orange. A similar reaction is given by gelatin and keratin. Analyses of xanthoproteic acid and its compounds made by Mulder and others are not of any value, as it has since been shown that this yellow substance is not constant in composition. The reaction is due to the aromatic radicle undoubtedly present in all proteids. On colour reactions of proteids see Salkowski (H. 12, 215), On colour Gnezda (Pr. 47, 202), Pickering (J. Physiol. 14).

(b) The liquid is rendered strongly acid with acetic acid, and solution of potassium ferro-cyanide added, which throws down the proteid

as a white flocculent precipitate.

(c) Millon's reaction. Millon's reagent' causes a white precipitate of the proteid. On boiling this precipitate and the surrounding liquid, both turn a brick-red colour. If only a trace of proteid is present there may be no initial precipitation. This test is given also by tyrosine, and it is in all probability owing to the aromatic radicle in proteids that those substances give it.

(d) Addition of a trace of copper sulphate and excess of potassium hydroxide causes a violet solution. In the case of albumoses and peptones the colour produced is a pink one (biuret reaction). See also Gnezda a. Pickering (loc. cit.) for similar reactions with nickel and cobalt.

(e) Proteids when dissolved in glacial acetic acid and treated with strong sulphuric acid exhibit a violet colour and faint fluorescence. and if sufficiently concentrated show an absorption spectrum very like that of urobilin (Adamkiewicz, B, 8, 161).

The reactions which are applicable to proteids which will not dissolve in water or neutral saline liquids, are the xanthoproteic, Millon's, and the Adamkiewicz colour reactions.

QUANTITATIVE ESTIMATION OF PROTEIDS.

A large number of different methods of estimating quantitatively the amount of proteid in a solution have been proposed and used; the polarimetric method has been much employed (Hoppe-Seyler, Virchow's Archiv, 11, 547). Among gravimetric methods various precipitants

¹ Millon's reagent. Equal quantities of mercury and strong pitric acid are mixed and gently warmed till the barecury is dissolved. The solution is diluted with twice the bulk of water, and the copious precipitate which forms allowed to settle. The supernatant liquid is the reagent.

of proteids have been suggested, e.g. tannin and sodium chloride (Girgensohn, N. R. P. 22, 557); hydrochloric acid and potassio-mercuric iodide (Brücke, Sitz. W. 1871), &c.; but the following methods are those most frequently employed:

(a) Clinical method. The rough method generally used for the comparison of albuminous urines consists in acidulating the urine, if it is alkaline, with acetic acid and then boiling it in a graduated tube. The flocculi which form are allowed to settle, and the proportion of the precipitate to the total volume of the liquid read off and expressed in fractions, such as a half, a tenth, and so on. Esbach's tubes are graduated to correspond to percentages of proteid; the precipitant being picric acid.

(b) Precipitation by heat. 50 to 100 c.c. of water are boiled and an accurately-weighed amount of albuminous fluid, about 15 or 20 g., poured in. The fluid is boiled for some minutes, a few drops of two per cent. acetic acid added, until the precipitate separates in flakes from a clear liquid. The precipitate is collected on a weighed filter, washed with water, alcohol, and ether, and finally dried, weighed, incinerated, and the ash deducted. This method is obviously applicable only to such proteids as are coagu-

lable by heat.

(c) Precipitation by alcohol. An accurately measured or weighed quantity of the liquid is mixed with three or four times its volume of spirits of wine, and set aside for some hours; the precipitate is then collected, washed with spirit, hot absolute alcohol, ether, warm water, and finally dried and weighed as before (Hoppe-Seyler, Handbuch, 3te Auft. 312). Or the liquid may be neutralised with acetic acid and mixed with ten times its volume of strong alcohol, and then boiled, the precipitate being treated as before (A. Schmidt, Pf. 11, 10; A. Hoffmann, Virchow's Archiv, 1879, 255).

(d) Precipitation with ammonium sulphate. Since Kühne (Z. B. 22, 423) has fully shown that saturation with this salt causes complete precipitation of all proteids but peptones, this method may be employed as follows for the quantitative estimation of these proteids:-The liquid is shaken or stirred with excess of the powdered salt, filtered, and the precipitate washed with saturated solution of ammonium sulphate. The filter with adherent proteid and salt is dried at 110°, by which means the proteid is rendered insoluble, and the salt can then be washed away with distilled water. The precipitate is then washed with alcohol and ether, dried, and weighed as before.

CLASSIFICATION OF PROTEIDS.

I. Albumins. These are proteids which are soluble in water, and not precipitable from their solutions by saturation with sodium chloride or magnesium sulphate. They are coagulated by heat. The important members of the group are egg albumin, serum albumin, and lactalbumin.

II. Globulins. These are proteids which are insoluble in water; they are soluble in dilute solutions of neutral salts; and are precipitated in an uncoagulated condition by saturation with sodium chloride and magnesium sulphate. They are coagulated by heat. The most important members of the group are: serum globulin, fibrinogen, myosin, crystallin, and globin.
III. Albuminates. This name is applied to

the metallic compounds of proteids, and also to acid albumin or syntonin, and alkali-albumin. Restricting the term to the two latter substances. they may be defined as proteids insoluble in water or in solutions of neutral salts, but readily soluble in dilute acids or alkalis. Their solutions are not coagulated by heat.

IV. Proteoses. These are proteids which are not coagulable by heat, and most of them are precipitable by saturation with certain neutral salts. They are precipitated by nitric acid, the precipitate dissolving on the application of heat and reappearing when the solution is cooled. They resemble peptones in being slightly diffusible, and in giving the biuret reaction. They are formed from other proteids as the result of the action of proteolytic terments on them, being an intermediate stage in the formation of peptones. They are also found in certain animal and vegetable tissues. The best-known members of the group are the albumoses.

V. Pentones. These are proteids which are very soluble in water; they are not precipitated by heat, by saturation with any neutral salt, nor by nitric acid. They are completely precipitated by tannin, by excess of absolute alcohol, and by potassio-mercuric iodide; incompletely by phosphotungstic acid, phosphomolybdic acid, and pieric acid. They give the biuret reaction. Peptones are subdivided into hemipeptones, those which yield leucine and tyrosine as the further result of pancreatic digestion, and antipeptones,

those which do not.

VI. Insoluble proteids. This class includes a number of proteids varying in their reactions which cannot be included in any of the foregoing classes, but which all resemble one another in their extreme insolubility in various reagents. This class includes fibrin, coagulated proteid, lardacein, antialbumid, and gluten.

DESCRIPTION OF THE PROPERTIES OF INDIVIDUAL PROTEIDS.

It will now be convenient to take the most important members of the various foregoing groups, and describe the characteristic properties of each. The animal proteids will be taken first.

CLASS I., ALBUMINS .- Egg albumin. This is the albumin occurring in white of egg; it may be separated from the globulin, which also occurs in that situation, by precipitating the latter with dilute acetic acid, or by saturation with magnesium sulphate. It is coagulated at a temperature of 70°-73°C. By fractional heat coagulation further pps. are obtained at 76° and 82° (Corlin a. Berard, Arch. de Biol. 9, 1). Its specific rotation is -35.5°. It is precipitated by agitation with ether. Crystalline egg albumin may be obtained by addition of an equal vol. of sat. sol. of ammonium sulphate and filtration to remove oviglobulin. On slow evaporation of the filtrate, crystals of egg albumin form (Hofmeister, H. 14, 165; Gabriel, 15, 456). Lieberkühn ascribed to albumin the formula

 $C_{22}H_{112}N_{18}SO_{22}$, Schützenberger $C_{248}H_{222}N_{18}O_{48}S_{2}$, Since Harnack (H.~5,~207) $C_{244}H_{222}N_{182}O_{48}S_{2}$. Since Lieberkühn attempted to establish the molecular weight of albumin by preparing and analysing

the copper compound, various investigations have been published bearing on the nature and composition of the compounds of albumin with the heavy metals, and especially with copper (F. Rose, Mitscherlich, Harnack, Bielitzki, Ritthausen, Lassaigne, &c. Further particulars will be found, with references to literature, in a paper by R. H. Chittenden and H. H. Whitehouse in Studies from the Laboratory of Physiol. Chem., Yale University, 2, 95). The results obtained are most contradictory, and illustrate that numerous compounds may be obtained by slightly modifying the conditions of precipitation; they are also very liable to dissociation. The only other proteid the metallic compounds of which have been studied is myosin; the percentage amount of the various metals in the compounds obtained differ from those formed from egg albumin (Chittenden a. Whitehouse, l.c.).

Uses of albumin. It is much used for clarifying vinous and syrupy liquids, as when boiled with it the heat coagulum carries down colouring matter and other impurities. In cookery white of egg is employed for this purpose, but in large operations, such as sugar refining, blood serum is used. Albumin is also largely used in photography, and in calico-printing for fixing colours. Its property of forming a hard compound with lime renders it useful as a coment in repairing earthenware. Spoilt albumin in print works may be recovered for practical purposes by the action of pepsin (Wagner a. Witz, Ď. P. J. 119, 166).

Scrum albumin. This is the albumin occurring in serum. Its specific rotation is -56°. Fractional heat congulation, and elementary analysis show that it is probably not a single proteid but consists in warm-blooded animals of three, a, β, and γ, coagulating respectively at 73°, 77°, 84° (v. Blood). Aronstein a. A. Schmidt (Pf. 2, 1) stated that serum albumin completely freed from salts by prolonged dialysis does not congulate by heat. This statement has not been confirmed by subsequent observers, who have found it impossible to free serum albumin from ash by this method, and have attributed the non-coagulation to a slight alkaline residue (Heynsius, Pf. 9, 514; Winogradoff, 2, 605; Hinzinga, 2, 392; Haas, 2, 378). On ash-free albumin sec also Harnack, B. 22, 3046; 23, 3745. Serum albumin is not congulated by ether. It is the proteid which most frequently occurs in morbid urine.

Serum albumin is not precipitated by saturating the scrum with magnesium sulphate; if, however, the globulin precipitated by this method be filtered off, and the filtrate saturated with sodium sulphate, the albumin is precipi-tated; this is due to the formation of sodio-magnesium sulphate (MgSO₄.Na₂SO₄.6H₂O) in the liquid (Halliburton, Journ. of Physiol. [5] 152). Albumin having nearly the same characters as serum albumin is found also in milk, muscle. lymphatic glands, and other tissues in small quantities.

CLASS II., GLOBULINS. - Serum globulin. (Synonyms, paraglobulin, fibrinoplastin, serumcasein.) This is the globulin occurring in serum. It is soluble in weak solutions of sodium chloride; it is partially precipitated when the 882 PROTEIDS.

percentage of sodium chloride reaches 0.03 to 1 0.07, re-dissolved on the addition of more salt, and again precipitated, though never completely, when the amount of salt present is 20 p.c. It is completely precipitated by saturation with magnesium sulphate. It does not coagulate on the addition of fibrin ferment, and probably takes no part in the formation of fibrin (v. art. BLOOD; v. also Hammarsten, Pf. 17, 447; 18, Its heat coagulation temperature is 75°C.
 The following methods have been suggested

for the separation of the globulin from the

albumin of serum:

(a) Dialysis. When the salts are dialysed the globulin is precipitated, the albumin remains in solution.

(b) Dilute the serum to 10 or 15 times its volume with water, and pass a stream of car-bonic acid through it, the globulin is precipitated (A. Schmidt, Arch. f. Angt. u. Physiol. 1862, 429); it is also partially precipitated by the addition of very weak acetic acid when the serum is similarly diluted (Panum, Arch. f. Pathol. Anat. 4); it was on account of this that a special alkali albumin or serum casein was formerly believed to exist in the blood.

(c) Saturation with sodium chloride precipitates the globulin, leaving the albumin in solution (A. Schmidt).

(d) Saturation with magnesium sulphate (Hammarsten). This is the only method commonly employed which effects a complete separation. Kauder has stated that half-saturation with ammonium sulphate will act similarly, and Halliburton (loc. cit.) that sodium acetate and sodium nitrate may also be used.

Serum globulin may be estimated quantitatively in serous liquids in the following way: a weighed or measured quantity of the liquid is saturated with magnesium sulphate, the precipitate collected on a weighed filter and washed with a saturated solution of magnesium sulphate, and then dried at 110 °C. for some hours; the proteid is thus rendered insoluble, and is freed from the salt by washing with water and alcohol. The precipitate is again dried on the filter to constant weight, weighed, and subsequently ignited and the ash deducted. In such a liquid as serum, viz. one containing a mixture of globulin and albumin, the latter may be estimated by deducting the amount of globulin from the amount of total proteids present.

Cell globulin found in lymph cells and other cellular structures coagulates at 47°-50°. A globulin (myoglobulin) which coagulates at 68°C. but otherwise resembles serum globulin

exists in muscle plasma.

Fibrinogen. This proteid, which occurs in blood plasma, very closely resembles the preceding; it differs from serum globulin in being completely precipitable by half-saturation with sodium chloride, and may thus be separated from that proteid (Hammarsten, Pf. 19, 563). It is precipitable by a stream of carbonic acid, but it is necessary to dilute the plasma with at least 20 times its volume of water before precipitation occurs, whereas serum globulin is precipitated when the dilution is less. It is coagulated by heat at 56°C. The heat coagulum is a very sticky one; the low temperature at which fibrinogen soagulates forms the basis of a method for esti-

mating it quantitatively: the coagulated proteid formed from the fibrinogen at 56°C. is collected on a weighed filter, washed with distilled water and alcohol, dried at 110°C., and finally weighed, ignited, and the amount of ash deducted (Fredericq). Under the influence of the fibrin ferment. fibringen is converted into fibrin; it is due to this change that blood coagulates when drawn, the fibrin entangling the blood corpuscles to form the clot. The term fibrinogen has been recently extended by Wooldridge to other ill-defined proteid substances which he considers to be precursors of fibrin. These are probably nucleo-albumins mixed with lecithin. For latest views on blood coagulation with references see Halliburton (J. Physiol. 13, 829; Goulstonian Lecture No. 3, Brit. Med. Jl. March 1893).

Plasmine. The term 'plasmine' was given by Denis (Mémoire sur le Sang, Paris, 1859) to the precipitate produced by saturating blood plasma with common salt; this has since been shown to consist of the two proteids, fibrinogen and serum globulin; serine was the name given to the proteid left in solution, or, as it is now

called, serum albumin.

Myosin. This is the proteid which is formed after the death of muscle; the muscle plasma separates into a clot composed of myosin, and muscle serum, as blood plasma separates into fibrin and blood serum. This produces a stiffening of the muscles called rigor mortis. The name given to the proteid precursor of myosin in the living muscle is myosinogen. The clot of myosin formed by diluting with water a saline extract of flesh is not so coherent as that of fibrin; it is readily soluble in 10 p.c. sodium chloride solution, from which it is precipitable by saturation with that salt or with magnesium sulphate; it forms a heat coagulum in such a solution at 56°C. Myosin is converted with great readiness into acid albumin or syntonin by weak hydrochloric acid; A. Danilewsky regards the compound so formed as being not ordinary syntonin but a combination of HCl with myosin, from which by suitable treatment myosin is recoverable. After long-continued dialysis, myosin can be freed from salts, and is thus rendered exceedingly insoluble, both in saline solutions and in dilute hydrochloric acid (A. Danilewsky, H. 5, 158; Halliburton, Journ. of Physiology, 8,

136). (See also Muscle.)
Vitellin. A proteid present in yolk of egg, which, although it resembles globulins in certain particulars, differs from them in not being precipitable by saturation with sodium chloride. Solutions coagulate at 70°-75°C. It is prepared by treating the yolk of hen's egg with ether, by which reagent most of the fatty and colouring matters are dissolved; vitellin remains undissolved as a white granular substance, which is insoluble in water, but readily soluble in dilute saline solutions. Nuclein appears to be united closely to, and may be obtained from, vitellin.

Crystallin. This was once called globulin, but that term has been extended to the whole group. It is obtained from the crystalline lens of the eye, composing, according to Berzelius, 85-9 p.c. of that structure. Its saline solutions become opalescent at 73°, but a coagulum is not deposited till 98°C. is reached. According to PROTEIDS.

Lehmann (Physiol. Chem. 1, 866) the formation of a heat coagulum is accompanied by the development of an acid instead of an alkaline reaction, as is the case with other proteids; he accounts for this by supposing that crystallin is united to ammonio sodic phosphate, which, on the application of heat, is resolved into ammonia and acid phosphate of soda. Valenciennes and Fremy (C. R. 44, 1122) state that other proteids are found in the lens, and have given the name phaconin to one in that of fishes (v.

also Béchamp, C. R. 90, 1255).

Hæmoglobin. When a solution of hæmoglobin, the red pigraent of the blood, is heated, the liquid becomes turbid, and a congulum of a reddish-brown colour separates out between 70° and 80°C. Heat decomposes the hamoglobin into two substances insoluble in water, one coagulated proteid, the other a colouring matter, hematin, which contains all the iron of the hæmoglobin. A similar decomposition occurs when hamoglobin is acted on by strong acids or alkalis, or by excess of alcohol. Prever described the proteid substance under the term globin, which is insoluble in water, and which swells in solutions of sodium chloride and sodium hydrate without dissolving. Kühne concludes from the action of reagents that a mixture of proteids rather than a single proteid results from the decomposition of hamoglobin; these would, however, seem to belong to the globulin class from the fact that hæmoglobin is precipitable from its solutions by saturation with such neutral salts as precipitate other globulins, and also by a stream of carbonic acid (v. art. HEMO-GLOBIN).

Hæmocyanin. This is a proteid associated with a colouring matter which takes the place of hæmoglobin as an oxygen-carrier in the blood of certain crustacea, arachnida, gastropoda, and cephalopoda. It was first described by Fredrica in the blood of the octopus; the blood which comes to the gills being colourless, and that leaving them being blue: the blue pigment is due to a loose combination of the proteid with oxygen, which, like oxy-hæmoglobin, parts with its oxygen to the tissues. Copper takes the place of the iron of hæmoglobin in this compound. It has not been separated into a pigment and a proteid, as hæmoglobin has. It coagulates by heat at 65°, and is precipitated by saturation with neutral salts, and by dialysis like other globulins (for references see Halliburton, Journ. of Physiol. 6, 800; Griesbach, Pf. 50.

CLASS III., ALBUMINATES.

Acid albumin. If a small quantity of dilute acid (hydrochloric or acetic) be added to serum or egg-albumin, no precipitation occurs, but after a short time it will be found that the albumin no longer coagulates on heating, and that its dextrorotatory power is increased. The albumin has been converted into acid albumin. On carefully neutralising such a solution with weak alkali, the whole of the proteid matter is thrown down as a white precipitate, which is soluble in excess of the alkali, and may be re-precipitated by neutralisation with weak acid, and again dissolved by excess of the acid, and so on. Acidalbumin is soluble in solutions of alkaline carbonates; it is precipitated, like globulin, by

saturation with sodium chloride or magnesium sulphate.

Acid-albumin may also be formed in a similar way from any globulin; myosin, for instance, is converted into acid albumin or syntonin, as it was first termed by Liebig, when prepared from muscle. The parapeptone of Meissner, which is formed in the first stages of peptic digestion, is also identical with acid albumin.

Alkali albumin. If, instead of dilute acid. dilute alkali be added to an albumin or globulin, coagulation by heat is similarly prevented, and the whole of the proteid is thrown down by neutralisation, and is soluble in excess of either acid or alkali. The name alkali-albumin is given to the proteid thus altered by alkali. Like acid albumin it is soluble in solutions of alkaline carbonates, and precipitated by saturation with sodium chloride or magnesium sulphate. In the presence of alkaline phosphates it is necessary to add more acid to obtain a precipitate than if the alkaline phosphate were absent; the acid is just used to convert the alkaline into neutral phosphate. When heated with strong solution of potassium hydrate, potassium sulphide is not formed.

Lieberkühn's jelly. When either tribasic phosphoric acid, acetic or tartaric acids, which do not precipitate moderately concentrated solutions of albumin, is added in excess to concentrated serum or white of egg, a jelly is produced which liquefies like gelatin on heating, and again solidifies on cooling. A similar jelly is formed by adding a strong solution of potesh to serum or white of egg. This substance, called Lieberkühn's jelly, is regarded as a variety of ac'd or alkali albumin respectively; it is soluble with difficulty in water; the aqueous solution remains, however, clear when boiled, and is precipitated by neutralisation.

Compounds of albumin with acids. On account of the present uncertain state of our knowledge concerning the constitution of the proteids, the statements concerning compounds which have been described of albumin with various acids must be received with caution, as is also the case with metallic albuminates (see

Egg albumin).

Trinitro-albumin C12H103(NO2)3N18SO22 in prepared by triturating or shaking dried and powdered albumin with 14 or 15 times its weight of nitric acid (HNO,); a gelatinous mass is the result, and on pouring this into water the in-soluble light-yellow tinted compound separates out. If the gelatinous mass be left to itself at a temperature below 10°, a small quantity of nitrogen tetroxide is given off, and a solution formed which, when diluted with water, deposits a dark-yellow tasteless hydroxytrinitro-albumin, $C_{72}H_{100}(NO_2)_2N_{10}(OH)_2(SO_2OH)O_{27}$. Both these compounds dissolve without alteration in dilute alkalis, from which solution they are precipitated in yellow flocculi on addition of acid (O. Loew, J. pr. [2] 5, 433). If, instead of using nitric acid, a mixture of concentrated nitric and sulphuric acids be employed, a bitter yellow pow-der, insoluble in water, alcohol, or dilute acids, but soluble in dilute alkalis, is obtained which is called hexnitro-albumin sulphonic acid, C₇₂H₁₀₁(NO₂),(SO₂OH)N₁₈SO₂₂; on treating this with ammonium sulphide, hexamido-albumin sulphonic acid $C_{rgH_{1ei}}(NH_2)_u(8O_xOH)N_{1e}SO_{22}$ is formed; this is decomposed by strong alkalis (J. pr. 29, 70, 110) distinguishes between casein with evolution of ammonia, and by nitric acid which forms the envelopes of the fat globules, with evolution of red fumes. It is insoluble in dilute acids, but readily dissolves in concentrated ones (O. Loew, J. pr. (2] 3, 180).

Gelatinous compounds of albumin with acids are prepared by leaving it twenty-four hours in a parchment paper dialyser and a dilute acid in the outer vessel. For a quantity of albumin represented by Lieberkühn's formula, C₇₂H₁₁₂N₁₈SO₂₂, the compounds contain 2 mols. nitric, 2 mols. hydrochloric, 1 mol. sulphuric, and 1\frac{1}{2} mols. phosphoric acid (G. S. Johnson, G. J. 27, 734).

Casein and Caseinogen. Caseinogen is the chief proteid in milk. By the action of rennet it is converted into a curd called casein. Caseinogen is thrown down by the addition of acetic or mineral acids, especially if the milk be first diluted; this precipitate when freed from fats is insoluble in water, soluble in dilute acids or alkalis (and alkaline carbonates), and re-precipitable by acidulation. It may also be prepared from milk by saturating it with magnesium sulphate, followed by washing the precipitate with saturated solution of that salt till the washings contain no albumin, and then re-dissolving the precipitated caseinogen by adding water. salt still adherent to the precipitate enables it to dissolve; the fat remains undissolved on the filter. Such a neutral solution of caseinogen becomes cloudy on heating, and the cloudiness disappears on cooling if the heating has not lasted too long. Lubavin states that caseinogen differs from alkali albumin in the following particulars: (1) when caseinogen is treated with caustic potash potassium sulphide is produced; (2) on digestion with artificial gastric juice, caseinogen yields a substance containing phosphorus, whereas an albuminate can be prepared from white of egg which contains no phosphorus (Lubavin, Hoppe-Scyler's Med. Chem. Untersuch. 1871, 468). C. Wurster (B. 20, 263) states that when hydrogen peroxide is passed through a solution of egg albumin in the presence of sodium chloride and an acid (lactic, acetic, phosphoric, or sulphuric) a proteid insoluble in water is thrown down, which he states to be a mixture of gelatinous acid albumin with a large quantity of proteid similar to caseinogen; he further supposes that hydrogen peroxide plays an important role in the living tissues of the body, and that the caseinogen of milk may be produced from the proteids of the blood by a similar means. The precipitate produced by adding ether to yolk of egg is also stated to have properties similar to

caseinogen (Bopp, A. 79, 16).

Most of the older writers use the word casein to include both it and caseinogen. Different varieties of casein have been described by different observers; Berzelius, Braconnot, and others described soluble casein, soluble in water, and unsoluble casein, insoluble in water (v. also Bopp, l.c.). The soluble casein probably consisted of the other proteids present in milk in addition to casein. More recently the view has, however, been again advanced that the only proteid in milk is casein; and that the apparent presence of albumin and other proteids is due to the action of reagents or ferments (Duclaux, C. R. 98, 378, 438, 526;

(J. pr. 29, 70, 110) distinguishes between casein which forms the envelopes of the fat globules, and that which exists in solution in the milk; both, however, have the same properties. A. Danilewsky (H. 7, 433) states that casein can be separated into caseo-protalbin, soluble in hot 50 p.c. alcohol, and caseo-albumin, insoluble in that reagent. Hammarsten (H. 7, 227) has, however, shown that this behaviour of casein depends in part upon its content of calcium phosphate, the presence of which impurity depends upon the use of hydrochloric acid in the precipitation of the casein, which acid does not favour the removal of the salt as well as acetic acid. Hammarsten, moreover, showed by elementary analysis that casein is a single body; this has been confirmed by Chittenden and Painter (Studies from the Lab. of Physiol, Chem., Yale Univ. 2, 156). The two last-named observers obtain the following as the percentage composition of casein: C, 53:30; H, 7:07; N, 15:91; S, 0:82; P, 0:87; O, 22:03. Hammarsten (H. 7, 269) and Ritthausen (Maly's Jahrsber, 1873, 28) have also published elementary analyses of casein.

It is owing to the presence of caseinogen that when rennet is added to milk a curd is produced, which is composed of the clotted casein and entangled fat globules; the whey or liquid residue contains the sugar, albumin, and salts of the milk. The spontaneous coagulation that sometimes occurs in milk is due either to the precipitation of caseinogen by lactic acid formed from lactose by fermentation, or to aërobic organisms which act like rennet. The coagulation that occurs when milk is boiled is due, not to the casein, but to the albumin in the milk. The ferment coagulation is a process which is entirely different from the precipitation by acid. A solution of pure caseinogen in dilute alkali will not coagulate on the addition of rennet; if, however, a small quantity of calcium phosphate or chloride be added, coagulation readily occurs. If caseinogen, precipitated by acctic acid, be well washed with water till the reaction is nearly neutral, and then neutralised with solid calcium carbonate, a pasty mass is formed which, on the addition of rennet thereto, sets into a solid clot; but here again if the caseinogen has been washed free from calcium phosphate rennet has no such action. This dependence of the rennet coagulation on the presence of earthy phosphate has been worked out by Hammarsten. The ferment causes the change from caseinogen to casein The lime salt combines with the latter and precipitates it. Hammarsten showed that on the coagulation of caseinogen by rennet a whey albumin easily soluble in water is formed in addition to the clot of casein. Soxhlet (J. pr. [2] 6, 1) states that alkaline solution of artificially prepared alkali albumin also coagulates on the addition of rennet, but this statement has not been confirmed. Metacasein is a name given to an early stage of the action of rennet and pancreatic juice on cascinogen. It coagulates by heat (Roberts, Proc. Roy. Soc. 1881; Edkins, Journ. Physiol. 12, 193).

Casein in the milk of different animals is stated by Simon to vary slightly; thus human casein is yellowish white, and very friable; it is incompletely precipitated from its aqueous solu-

PROTEIDS. 836

tion by alum or by acetic soid. Casein from cow's milk is less soluble in water, and becomes viscid and horny on drying. Canine milk gives a casein which does not become viscid and horny when dried, and is less soluble in water. Human casein is much more easily digested than that of cow's milk, which is more viscid, and sets into a more solid clot under the influence of the rennet ferment of the gastric juice. For recent papers on casein see Ringer, Journ. Physiol. 11, 464; 12, 164; Halliburton, 11, 459; Sebelien, 12, 95; Hewlett, 13, 798.

CLASS IV., PROTEOSES .- Under the name proteose it is convenient to include the large number of products which are intermediate in the formation of peptones from other proteids. Similar substances are formed by the action of both the peptic and tryptic ferment; those formed from fibrin or egg albumin have received the name ofalbumose; from globulin, globulose; from casein, cascose; from vitellin, vitellose, &c. various substances resemble each other in their general reactions, and differ from one another in origin, slightly in percentage composition, and in a few minor reactions. The albumoses are those which have been most studied. It will be sufficient here to describe the properties of the varieties of albumose. The globuloses, vitelloses, &c., are divided into similar varieties, with corresponding prefixes.

The properties of these substances have been chiefly worked out by Kühne and Chittenden. The names first given to them were propeptone (Kühne) and a peptone (Meissner). Kühne then adopted the name albumose, and subdivided the albumoses into hemi-albumoses, those which are converted into anti-peptones. Ampho-albumose is a term which includes both hemi- and anti- varieties.

The following are the chief albumoses:

- (i.) Proto-albumose, soluble in distilled water and weak saline solutions, partly precipitated by saturating its acidified solutions with sodium chloride. It is also precipitated by mercuric chloride and by copper sulphate.
- (ii.) Hetero-albumose, insoluble in distilled water, soluble in weak saline solutions, and completely precipitated therefron either by dialysing out the salt or by saturation with sodium chloride. It is precipitable by mercurio chloride only in acid solutions; it is precipitated by copper sulphate. By heating its saline solutions a cloudiness is produced, which is not caused by the formation of coagulated proteid, since it readily disappears on the addition of weak acid or alkali. By the action of alcohol hetero-albumose is partially converted into an insoluble product (dys-albumose).
- (iii.) Deutero-albumose. This is the albumose most nearly allied to peptone. It is soluble in distilled water, and in saline solutions; it is not precipitated by saturation with sodium chloride. It is precipitable by nitric acid only in the presence of excess of salt, and then does not dissolve so readily on heating as in the case of the other albumoses. It is precipitable by mercuric chloride, but not by copper sulphate. It can be separated from peptones by saturation with ammonium sulphate, which precipitates

deutero-albumose but not peptones. For latest work on this see Kühne, Z. B. 29, 1.

The above reactions are those in which the albumoses differ from one another; they resemble one another in their characteristic behaviour with nitric acid (already described), and in giving the birret reaction. Noumeister says that in the formation of peptones from albumin, in the first stage of digestion, proto-albumose (chiefly a hemi-product), hetero-albumose, and anti-albumid (an insoluble product only partially further changed, and that into antipeptone) are formed. Deutero-albumose is in all cases an intermediate product between these and the final poptones.

The following are the chief papers published in reference to this subject. On albumoses: Kühne and Chittenden, Z. B. 20, 11; R. Noumeister, ibid. 23, 381; Chittenden and Bolton, Studies from the Physiol. Lab., Yale Univ. 2, 126. On globuloses: Kühne and Chittenden, Z. B. 22, 409. On vitelloses: Neumeister, ibid. 23, 402. On caseoses: Chittenden and Painter, Studies from the Physiol. Lab., Yale Univ. 2, 156. On the digestion of casein: H. Thierfelder, H. 10, 577. On benzoylated ethers of the albumoses: Schrötter, B. 22, 1950.

CLASS V., PEPTONES. -The general reactions of these substances and of their chief varieties. hemi- and anti- peptone, have been already described. It is only since the introduction of the method of separating them from other proteids by saturating a solution containing such a mixture with ammonium sulphate that they have been obtained free from proteoses. Most of the peptones of commerce consist almost entirely of protecses. Peptones have also been described as occurring in milk, and in certain animal and vegetable tissues, whereas these proteids are in reality proteoses artificially formed during manipulation. Certain properties previously ascribed to peptones, e.g. a power of preventing blood from coagulating after intravenous injection, are now known to be due to proteoses.

When peptones are formed artificially a bitter taste is developed; what this is due to is unknown. Pure peptone has a meaty or cheesy taste; the albumoses are also free from bitterness. It is exceedingly difficult to dry pure peptone, and when dry it hisses and froths, with evolution of heat on the addition of water.

Anti-peptone—and the same appears to be true of other anti-products of digestion (e.g. anti-albumid)—do not only not yield leucine and tyrosine on further pancreatic digestion, but appear not to contain the tyrosine radicle; they do not give Millon's reaction, and do not yield tyrosine on boiling with sulpluric acid.

(For the most recent paper on peptones, methods of purification, and ultimate analysis, see Kühne and Chittenden, Z. B. 22, 423.)

CLASS VI., INSOLUBLE PROTEIDS.

Fibrin. This is the proteid formed from fibrinogen, probably under the influence of a ferment derived from the white corpuscles of the blood. It is owing to its formation that blood clots after withdrawal from the body (see Blood). It may be prepared pure by washing the clot free from corpuscles by a stream of water, or better, by allowing the plasma freed from corpuscles to coagulate, and then it is

washed free from other proteids by water. It is a white elastic solid, usually exhibiting fibrillation under a high magnifying-power. It is insoluble in water, partially soluble in dilute saline solutions, the proteid which goes into solution having the properties of serum globulin. Fibrin possesses the power of liberating oxygen from solutions of hydrogen peroxide. Fibrin swells up in cold weak hydrochloric acid (0·1 p.c.); it dissolves, forming acid albumin, on heating it with weak hydrochloric acid. It is readily digested by pepsin or trypsin, yielding albumoses and peptones. Hasebrook (H. 11, 348) and A. Herrmann (ibid. 11, 508) state that a first product in the digestion of fibrin is a substance with many of the properties of fibrinogen. (For elementary analyses and varieties of fibrin see Hammarsten, Pf. 22, 484; 30, 437. See also Fibrinogen.)

Cagulated proteid. This is proteid converted by heat or alcohol into a coagulum. It is insoluble in water or dilute acids or alkalis; it is, however, like fibrin, readily digestible by

proteolytic ferments.
